New Pharma-Ject™ adaptor and prefilled syringes of preservative-free Morphine Sulphate Injection

- Presentation specifically designed for use in patient controlled analgesia.
- Manufactured to exacting standards for precise drug delivery, even at low flow.
- Prefilled syringes with preservative-free morphine sulphate injection 50mg/50ml and 100mg/50ml.
- Pharma-Ject™ adaptor and syringes separately packaged for convenient and easy storage.

A World of Health

DATE OF PREPARATION: SEPTEMBER 1997. D/97/050

' **Pharma-Ject™ Morphine Sulphate Injection B.P.** is a clear sterile solution of morphine sulphate in Water for Injections, able in 50mg/50ml and 100mg/50ml presentations as a prefilled syringe. **Indications:** Continuous intravenous infusion in nts with severe pain or use with controlled rate infusion pumps in accordance with appropriate protocols for patient controlled jesia (PCA). **IV infusion dosage:** Should be titrated according to requirements. Most adult patients can tolerate a starting ge of 0.5 to 1.0mg/hour. As with other narcotics, a reduction in dosage may be advisable in the elderly. In children, an infusion of 10 to 50mcg/kg/hour morphine is recommended. A maximum intravenous dose of 4mg/hour should be exceeded with on. **Patient-controlled analgesia:** For adults, demand doses of 0.05 to 1.5mg morphine have been given via PCA using a out interval of 6 to 10 minutes. If a background infusion is adopted, a dose of 1 mg/hour morphine is often used in adults. n, a reduction in dosage may be advisable in the elderly. There is limited clinical experience of the use of patient-controlled jesia in children. A demand dose of 0.01 to 0.025mg/kg morphine has been used in children and adolescents between the of 7 and 19. If a background infusion is employed, an infusion dose of 0.015mg/kg/hour morphine may be used in children. **effects:** Essentially the same as those observed with other opioid analgesics. Include the following major hazards: respiratory ession, apnoea and to a lesser degree circulatory depression, respiratory arrest, shock and cardiac arrest. Less hazardous non adverse effects: Constipation, light-headedness, dizziness, sedation, nausea, vomiting, sweating, dysphoria and euphoria. r adverse reactions include: Flushing of the face, chills, tachycardia, bradycardia, palpitations, faintness, vertigo, syncope, thermia, hypotension, orthostatic hypotension, and hypertension. Weakness, headache, agitation, tremor, uncoordinated le movements, insomnia, confusional symptoms and occasionally hallucinations. Dry mouth, anorexia, laryngospasm, colic, hormone secretion. Blurred vision, nystagmus, diplopia and miosis. Pruritus, urticaria, other skin rashes and oedema. Withdrawal (abstinence) syndrome. Pain at injection site; local tissue irritation and induration following subcutaneous injection, particularly when repeated. **Contra-indications & warnings:** Known hypersensitivity to morphine. Acute or severe bronchial asthma; respiratory insufficiency or depression; obstructive airways disease; severe CNS depression; following biliary tract surgery or surgical anastomosis; biliary colic, hepatic disease gastrointestinal obstruction, delayed gastric emptying, paralytic ileus; patients concurrently on MAO inhibitors; cardiac arrythmias; heart failure secondary to pulmonary disease; acute alcoholism; head injuries; brain tumour; raised intracranial or cerebrospinal pressure and in convulsive states such as status epilepticus, tetanus or strychnine poisoning. PCA in young children and adults with poor cognitive function is contraindicated. Patients with hepatic disease. Morphine can produce drug dependence. Morphine should be used with caution in patients with any of the following: Renal dysfunction, shock or compromised ability to maintain blood pressure, predisposition to supraventricular tachyarrhythmias, hypothyroid state, Addison's disease, prostatic hypertrophy or urethral stricture. Pregnant patients should only be given morphine when the benefits clearly outweigh potential risks to the foetus. Breast-feeding is not recommended while a patient is receiving morphine. Morphine is not recommended for use in women during and immediately before labour. Morphine overdose is characterised by severe side effects as listed above. Management may include the use of opiate antagonists, ventilation and other supportive measures as necessary. **Legal category:** POM CD. Full prescribing information available from Faulding Pharmaceuticals plc or from the Summary of Product Characteristics. **Price: 50mg/50ml £9.50, 100mg/50ml £10.50. PL4515/0089 & PL4515/0090 Product Licence holder:** Faulding Pharmaceuticals plc, Tachbrook Park, Warwick, CV34 6RS. DBL® is a registered trademark of F. H. Faulding & Co. Limited.

Frontline 690

Blease Frontline Plus™

one less thing to worry about'

Some anaesthesia machines are so complicated, they demand more attention than your patient. It's the last thing you need in the middle of a hectic day, perhaps even in unfamiliar surroundings. The Frontline on the other hand, is ergonomically designed and user-friendly. Giving you one less thing to worry about.

A modular machine with all the benefits of an integrated system, but with none of the disadvantages, the Frontline is flexible enough to be tailored to your needs. Developed as a result of consultation with leading anaesthetists and hospital personnel, it uses the most up to date technology to ensure that even your toughest anaesthesia needs can be met – whatever your environment.

The Blease Frontline Plus™ - a simple answer in an ever complicated world.

INSPIRED THINKING IN HEALTHCARE

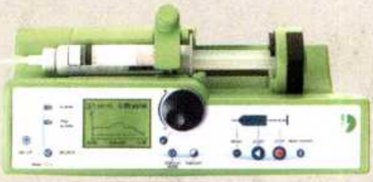
MASTER TCI

To master the art of target controlled infusion for anaesthesia



Master TCI

Master TCI is the first Target Controlled Infusion system to be CE approved. Master TCI offers important advantages (essential for daily pratice of TCI):

- graphical display of the calculated blood and effect site concentration curves.
- Selectable induction duration
- Convenient control
- Continuous display of the recovery time prediction.

Master TCI incorporates the pharmacokinetic model for propofol developed by Zeneca Laboratories. Patient data storage, print-out and downloading capabilities make Master TCI the adequate tool for anaesthesia and Patient Data Management Systems. Master TCI and Pilot Anaesthesia perfectly tailored for I.V. therapy.

GUIDE TO AUTHORS OF ESA ABSTRACTS

ESA encourages non-native English speakers to submit abstracts, and looks forward to receiving abstracts for the ESA congress in 1999. Please try to write as simply as possible and avoid language mistakes. After submission each anonymous abstract will be judged by three reviewers, and accepted abstracts will be published as a supplement to the May 1999 issue of the *BJA – International Journal of Anaesthesia*. The size of the original material will be reduced to 80%: please be sure that your abstract, **particularly any graphs**, can be read easily after this has been done.

Follow these rules **exactly**:

1. Use the example for layout. Use Times Roman or similar font with a size no smaller than 12 point. Dot matrix printing is not acceptable.

2. You **must** use the following headings for a structured abstract layout:

Background and Goal of study. The problem being addressed, and if relevant, the hypothesis to be tested.

Materials and Methods. Avoid abbreviations if possible; do not invent new abbreviations: if you must use abbreviations, try to use explicit ones e.g. prop, thio. Indicate statistical tests used.

Results and Discussion. The salient results. Use SI units for all measurements. One figure or table can be used and must lie within the boundaries. Give an index of variation and say what it is: e.g. standard deviation, 95% confidence intervals. Make absolutely sure that the symbols and text in a figure are large enough to allow reduction. Do not use three dimensional columns, dotted gridlines, or other unnecessary artwork in your figure. Reset the "default" graph in your computer!

Conclusion(s). What you conclude from the results.

References. Up to three references, numbered according to order of occurrence in the text, with the corresponding number in the text. Use the following layout and punctuation: Author names up to three (followed by et al if more) Journal title abbreviated as for Index Medicus year of publication;volume number:starting page number–finishing page number. Thus: Adam AB Eve Q Cain OM et al Clin.Sci. 1997;**99**:45–99.

Acknowledgements including financial support.

3. Prepare a version of the abstract with the author names removed and remove any text that could "unblind" the abstract. Submit the original abstract with three copies of **each** version of the abstract along with a **single** sheet with the following to allow indexing in *BJA*: Title of Abstract, List of Authors, Key words.

4. Complete a submission letter for **each abstract** you send which includes the statement signed by the Senior Author and the presenter.

5. Send these preferably by e-mail or in a stiff cardboard-backed envelope to arrive no later than December 1st 1998. Another possibility to submit electronically is via the Internet. Abstract form, cover letter and statement form will be available on our Internet address, www.euroanesthesia.org, from October 1st 1998. Abstracts which arrive after December 1st will not be considered. Faxed copies are not acceptable. Abstracts which do not fulfil the above guidelines will be returned. Authors will be informed, by fax if a number is given, within 10 weeks of the dead line date if their abstract is not accepted and within 14 weeks if the abstract is accepted.

Submit abstracts to:

The ESA Secretarial Office
c/o C.U.B. Erasme
Route de Lennik, 808
B-1070 Brussels
Belgium

Fax: +32 2 555 43 35
http://www.euroanesthesia.org

The ESA strongly recommends electronic abstract submission via the Internet for the 1999 congress in Amsterdam. It will not only be cheaper for you but also more reliable and save us lots of time. Electronic abstract submission will be available from the October 1st 1998. Deadline for electronic submissions to the 1999 congress is December 1st 1998. Look us up under the address **www.euroanesthesia.org** for further information on how to submit your abstracts, register for the 1999 congress and become an ESA member. Abstracts can also be submitted by e-mail to fbonnet.tenon@invivo.edu

EUROPEAN SOCIETY OF ANAESTHESIOLOGISTS

Cover letter for abstract submission 1999

This letter must be filled out completely and submitted with each abstract or the abstract will be rejected. All abstracts and completed cover letters must arrive no later than **December 1, 1998** in a stiff cardboard-backed envelope.

Please type in the space provided, in order, on separate lines, the following information:

1. Title of abstract
2. Name(s) of each author(s) in order, on separate lines with presenting author first
3. Name of Institution, City, State (only one institution, please) (exactly as you wish to see these entered in the programme)
4. Session preference (choose from list below)
5. Presentation preference (verbal, poster, or indifferent)
6. Name and Address of Presenter for use in correspondence
7. Telephone and Fax numbers.

Sessions

Epidemiology in anaesthesia and intensive care
Outpatient anaesthesia
Patient Safety: equipment, monitoring and computers
Circulation
Respiration
Transfusion and haemostasis
Neurosciences
Local and Regional anaesthesia
Pharmacology
Paediatric Anaesthesia and Intensive Care
Obstetric Anaesthesia
Intensive Care Medicine
Resuscitation and Emergency Medicine
Acute and Chronic Pain Management

You must **Complete and Sign the statement on the reverse of this form** for **each abstract** that you submit.

STATEMENTS

The work in the enclosed abstract will not be presented to a large English-speaking meeting before the 1999 ESA meeting.

The work will not appear in another form at that meeting.

The work will not be published before the 1999 meeting, in whole or in abstract, in an indexed journal.

For studies involving animal or human subjects: I have satisfied the requirements of my institution or organization regarding the use of human subjects or animals in research.

In consideration of the **European Society of Anaesthesiologists** taking action in reviewing and editing my/our submission, the author(s) under-signed hereby transfer(s), assign(s), and otherwise convey(s) all copyright to ownership in said work to the European Society of Anaesthesiologists in the event said work is published by the Society. I/We understand that this copyright assignment applies only to the abstract submitted herewith and does not apply to, or prevent, subsequent publication elsewhere of a full manuscript relating to the subject matter of such abstract.

This section is for you to confirm that you have submitted your materials correctly.

Checklist for Submissions

	Check
Original abstract	☐
Three copies of abstract	☐
Three copies of a blinded abstract	☐
Sheet with author names, title, and key words	☐
Signed covering letter for *each* abstract	☐
Telephone and Fax numbers with country and city codes	☐

EUROPEAN SOCIETY OF ANAESTHESIOLOGISTS
ANNUAL CONGRESS
25 April–28 April, 1998

PROGRAMME

8:30–10:00 Sunday 26 April 1998 — Room "A"
EPIDEMIOLOGY (ORAL SESSION)

Abdominal aortic surgery cardiac enlargement on preoperative chest x-ray as an independent predictor of postoperative left ventricular failure .... A 1
A. Declerck, J Karayan, K. Dhoste, D Thomas, J. Fusciardi

Preoperative thallium imaging and coronary revascularization in critical limb ischaemia. impact on perioperative morbidity and long-term survival .... A 2
G. Landesberg, Y. Wolf, M. Mosseri, D. Schechter, M. Bocher, H. Anner, Y. Berlatzky

Electrocardiographic and cardiokymography stress testing for cardiac risk assessment in patients undergoing non-cardiac surgery . A 3
A Gauss, H.J. Roehm, A Schaeuffelen, T. Vogel, U. Mohl, M. Georgieff, W Schuetz

Preoperative coronary angiography in patients undergoing abdominal aortic surgery: five years' experience .... A 4
D Eyraud, M. Bertrand, M.H. Fléron, B. Riou, P Coriat

Hypertension and perioperative cardiovascular complications. meta-analysis of observational studies A.5
S.J. Howell, J.W. Sear, P. Foex

Laparoscopy *vs* laparotomy for cholecystectomy in elderly patients .... A 6
M. Zając, K. Zając, Zb Engel

14:00–15:30 Monday 27 April 1998 — Room "A"
EPIDEMIOLOGY (ORAL SESSION)

Evaluation of Possum as a tool for quality assurance in an anaesthesiological ICU A.7
K. Schulze, R. Uebelen, Lj. Verner, A Bornscheuer, H Hecker, S Piepenbrock

Development of a high dependency unit illness severity scoring system A.8
K Stuart-Smith, C. Spring, E. Whitley, A. McCrirrick

Early prognosis value of SAPS II score after orthotopic liver transplantation .... A 9
P. Revel, R. Valles, E. Arthot, F. Semjen

Using revised simplified acute physiology score (SAPS II) in patients admitted to a neurosurgical intensive care unit A.10
D Siao, G. Boulard, B Grenier, R. Mesli, P. Maurette

Study of admissions for iatrogenic disease in a polyvalent intensive care unit A.11
P Jeanjean, M Andrejak, M. Ossart, M. Slama

Head injury-induced haemostasis impairment. .... A 12
A Peyclit, D. Cailloce, P B. Petitcolin, G. Pithan, P. Feiss, N. Nathan

10:45–12:15 Sunday 26 April 1998 — Room "A"
EPIDEMIOLOGY (POSTER SESSION)

Perioperative silent myocardial ischaemia. an indicator of postoperative morbidity or mortality? A.13
G.W.G. French, Z Rashid, H. Lam, J W. Sear, P. Foëx, S.J Howell

Cardiac troponin I for diagnosis of postoperative myocardial infarction in cardiac surgery .... A 14
J. Silleran, A Fiemeyer, M. Paris, J.F. Baron

Postoperative troponin Ic cut-off value is reliable with early cardiac complications after aortic repair A.15
G. Godet, S.B. Ayed, M.A. Bernard, C Baillard, M. Bertrand, C. Huraux, E. Kieffer, P. Coriat

Incidence and causes of cardiac arrests related to anaesthesia in 10 769 administrations A.16
J. Dubourdieu, P. Biboulet, P Aubas, X. Capdevila, Y Ryckwaert, Y Barthelet, F. d'Athis

Morbidity-mortality rates and risk factors after carotid endarterectomy A.17
A.F Moure, R. Segura, B Fernández, A. Pensado, P. Pose

Impact of the introduction of a daytime emergency operating theatre in a neurosurgical centre: prospective audit .... A 18
E V. Addy, C.F. Kearns, N.F. Maartens

Analysis of documentation of patient data in anaesthetic records in a university teaching hospital .... A 19
T.K. Tan, B.A. Crooks

Perioperative infusion of dobutamine: effects of morbidity and mortality A.20
A. Donati, D. Achilli, R. Coltrinari, D. Battisti, P. Bechi, L. Mariani, S Caporelli, P. Pietropaoli

Effect of thoracic epidural analgesia on postoperative complications after cardiac surgery – a prospective study A.21
D. Turfrey, D. Ray, N. Sutcliffe, P Ramayya, N. Scott

Influence of cardiopulmonary bypass-related factors in postoperative renal failure .... A 22
S. Garrido, M.J. Martín, A. Toral, P. Rama, S. Rodiño, A. Figueira

Fast-track recovery in cardiac surgery: experience in a public hospital A.23
H. Litvan, A Flo, J.M. Campos, J.A. Fernandez, J. Galan, J. Montiel, A. Aris, J.M.V. Landeira

10:45–12:15 Monday 27 April 1998 — Room "A"
EPIDEMIOLOGY (POSTER SESSION)

Serum creatinine cannot predict renal impairment in the perioperative period A.24
A. Zubicki, M L Cittanova, K Zaier, C Montalvan, N Nefaa, P. Coriat

Patient knowledge of anaesthesia and perioperative care in an Irish teaching hospital A.25
J. Laffey, M. Coleman, J. Boylan

Unintended decreasing body temperature: a stepchild of perioperative care and outcome consequences .... A 26
R. Uebelen, K. Schulze, D. Müller, H. Ruckoldt, M. Bund, S. Piepenbrock

Single-dose antiemetic treatment of postoperative nausea and vomiting in the recovery room is insufficient .... A 27
L H J. Eberhart, A M Staack, A.M. Morin, M Georgieff, W. Seeling

Multifactorial treatment including ondansetron eliminates postoperative nausea and vomiting .... A 28
K Zając, M Zając, A Ciaćma

Sixty per cent of patients can be extubated in the operating room after orthotopic liver transplantation A.29
E Cerutti, G Massano, R. Romagnoli, E. Castenetto, M. Schellino, F. Gennari, G Fagiano, M. Salizzoni

Preoperative risk factors for postoperative renal impairment after aortic surgery A.30
M.L. Cittanova, K. Zaier, N. Dieudonné, A. Zubicki, B. Riou, P. Coriat

Anaesthetic morbidity during laparoscopic surgery A.31
D. Milon, A. Rauss, H Musellec, M Gentili, F Bonnet

Early morbidity and mortality and risk factors in patients undergoing lung resection for lung carcinoma A.32
E del Barrio, G. Varela, M. Jiménez, I. Torán, P.G. Cosmes, C. Muriel

Rate of lower respiratory tract infection in intensive care units: an Italian multicentre observational study A.33
G Sangiorgi, M. Antonelli, E. Manso, A Brienza, A Gasparetto, E. Magliano, G. Martinelli, G. Montanari

13:00–14:30 Saturday 25 April 1998 — Room "A"
OUTPATIENT ANAESTHESIA (ORAL SESSION)

Inhalational induction for day-case anaesthesia: patient and anaesthetists' acceptability A.34
A J. Byrne, A S Wolverson

Propofol *vs* sevoflurane in short surgical gynaecological procedures A.35
A. Suarez, E Guasch, I. Fornet, A. Longarela, F.J. Palacio

A double blind comparison of sevoflurane *vs* propofol and mivacurium for tracheal intubation in day case wisdom tooth extraction A.36
A Thwaites, I. Smith

Sevoflurane *vs* propofol in day-case surgery anaesthesia A.37
N. Kokot, S. Rzymski, M. Gaca

Sevoflurane *vs* propofol for ambulatory anaesthesia: a cost-effectiveness analysis A.38
N. Nathan, A. Peyclit, A Lahrimi, P. Feiss

Postoperative nausea and vomiting in day-case arthroscopy patients A.39
M.B. Hough, B. Sweeney

14:00–15:30 Sunday 26 April 1998 — Room "A"
OUTPATIENT ANAESTHESIA (ORAL SESSION)

Propofol autocoinduction in ambulatory anaesthesia A.40
P. Ribes-Pastor, G. Djaiani

Remifentanil *vs* fentanyl in ultrashort gynaecological day surgery A.41
M. Mulas, D. Sances, E Sabbia, G. Pala, P. Rulu

Target-controlled remifentanil in combination with propofol for spontaneously breathing day case patients: effects on respiration A.42
J.A.C. Murdoch, R.A. Hyde, G.N.C. Kenny

Rapid recovery from anaesthesia with remifentanil and isoflurane, enflurane or propofol may enable more inpatient, short surgical procedures to be performed as day-cases A.43
J.-P. Muller, F. Chung, J. Scholz, H. Breivik, M. Araujo, K Hjelle, B. Upadhyaya, C. Haigh

Remifentanil and desflurane – an ideal combination for rapid recovery? A.44
A. Biedler, W. Wilhelm, K. Berg, A. Langhammer, C. Bauer, R. Larsen

16:15–17:45 Sunday 26 April 1998 — Room "A"
OUTPATIENT ANAESTHESIA (POSTER SESSION)

Blood alcohol concentration and psychomotor effects on skills associated with driving ... A 45
S Grant, G N.C. Kenny, K. Millar

Blood propofol concentration and psychomotor effects on skills associated with driving ... A.46
S Grant, J. Murdoch, K. Millar, G N.C Kenny

Assessment of balance using computerized dynamic posturography after day-case anaesthesia for nasal surgery ... A.47
M.G. Parry, H Glaisyer, P. Bailey

Predicting factors from unanticipated admission following ambulatory surgery ... A 48
M.J. Linares, M.D Pelegrí, F Pi, E Izquierdo, L Parra, P Gambús, A Abad, F Sanchez, R Masia

Patients' experiences of day surgery ... A.49
T. Kangas-Saarela, J. Ohukainen, M. Koivuranta

Day case laparoscopic cholecystectomy: the anaesthetic experience ... A 50
R.G. Miller, E.A. Clements, M Virdi, J.M. Wellwood

Bispectral analysis of the EEG to compare the hypnotic effects of inhalation (sevoflurane) *vs* intravenous (propofol) anaesthesia induction in day surgery patients ... A 51
E Van Den Eeden, C. De Deyne, M Struys, J P. Schiepers, J Deghislage, E. Vandermeersch, R. Heylen

Comparison of three methods of inhalation induction with sevoflurane in adults ... A.52
J. Rodrigo, R. Martin-Larrauri, J I. Gómez, P Vila, G Blanc, A Biarnés, L Usón

Cost minimization comparison of sevoflurane compared with propofol and isoflurane in gynaecological day-case surgery ... A 53
I M. McMenemin, T.B Lytle, S.J. Coles

16:15–17:45 Monday 27 April 1998 1998 — Room "A"
OUTPATIENT ANAESTHESIA (POSTER SESSION)

The ingestion of caffeine and the appearance of headache postoperatively or after an endoscopy or an x-ray procedure ... A 54
A K Zacharof, K Petrogiannopoulos, K. Mauronaslos, M Papadakis, J. Poulikakos

Spinal anaesthesia with hyperbaric bupivacaine 0.1% in ambulatory perineal surgery ... A 55
J. Rodríguez, L Martín, J. Sobrino, M Varela, R. Cabadas, J. Blanco

Comparison of rocuronium and mivacurium during outpatient surgery. propofol *vs* sevoflurane ... A 56
A Robert, C Plasman, J Massaut

Effect on postoperative nausea and vomiting by antagonizing neuromuscular block ... A 57
O Engdahl, S. Anskàr, S. Öster, C. Svedenhammar

Patient-maintained propofol sedation for premedication in day case anaesthesia ... A.58
J.A C. Murdoch, G.N.C. Kenny

Patient controlled sedation for colonoscopy ... A.59
C. Seavell, C. Roseveare, J Criswell, H. Shepherd, P Patel

Accuracy of waking time estimation after sedation by a computerized target-controlled infusion system ... A.60
E. Knolle, R. Fricker, S. Stoklas, H.G. Kress

Inspired concentrations of desflurane and isoflurane required for equivalent rates of inhaled induction ... A 61
W. Stevens, A Bengtsson

Cost minimization comparison of sevoflurane compared with propofol and isoflurane for the induction and maintenance of anaesthesia in day case surgery ... A 62
J.M Murray, C.W. Renfrew, T.B Lytle, S J. Coles

15:00–16:30 Saturday 25 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

Evaluation of respiratory problems during prolonged usage of cuffed oropharyngeal airways Comparison with laryngeal mask airway ... A.63
G.S. Voyagis, V Dimitriou, A. Tragou, N. Charisi, V Georgakopoulou

Choice of cuff inflation medium during nitrous oxide anaesthesia ... A.64
V Mitchell, T. Adams, I. Calder

Attenuation of vasomotor responses to tracheal intubation. Comparison of tramadol, pethidine, nalbuphine and placebo ... A.65
A A. van den Berg, E Halliday

Airway management and the incidence of sore throat ... A.66
E V. Addy, A. Kapila, C. Verghese

Swallowing after thyroidectomy in patients over 70 years of age without recurrent laryngeal nerve damage ... A 67
L Lacoste, J.C Ferrié, P. Ingrand, F. Lebrun, J. Fusciardi

Swallowing after thyroidectomy: impact of recurrent laryngeal nerve damage in patients less than 70 years of age ... A.68
L. Lacoste, J.C. Ferrié, P Ingrand, M S. Lehuédé, J Fusciardi

Effects of endotracheal intubation and laryngeal mask airway insertion on the risk of myocardial ischaemia in cardiac patients ... A.69
B. Ay, Z. Eti, A.S. Fak, T. Umuroğlu, F.Y Göğüş

Use of a cuffed oropharyngeal airway to assist fibreoptic laryngoscopy and tracheal intubation using the Portex bougie A.70
M Hawkins, E. O'Sullivan, P. Charters

Optimum cuff inflation in cuffed oropharyngeal airway A.71
V Dimitriou, G.S. Voyagis

Clinical evaluation of the cuffed oropharyngeal airway during positive-pressure ventilation A.72
B Haberland, H. Kühne, H. Guggenberger, K. Unertl

10:45–12:15 Sunday 26 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

A comparison of the laryngeal mask airway and the cuffed oropharyngeal airway for manual positive pressure ventilation .... A 73
G.S. Voyagis, V. Dimitriou

Comparison of cuffed oropharyngeal airway and laryngeal mask airway A.74
L. Versichelen, M. Struys, G. Rolly

Use of esmolol to attenuate haemodynamic responses to tracheal intubation, eye bandaging and tracheal extubation during cataract surgery A.75
A.A van den Berg

Intubation without muscle relaxants in Mallampati grade III and IV patients with mandibular fracture A.76
J. Kalinowski, I Furman, M. Mikaszewska, R. Uryszek, E. Mayzner-Zawadzka

Safety and simplicity of difficult tracheal intubation management: comparison of the Bullard laryngoscope with the video-optical intubation stylet in a mannequin A.77
M. Weiss, U. Schwarz, A.Ch. Gerber

Evaluation of McCoy laryngoscope in routine laryngoscopy .... A 78
D. Francon, P. Guerre-Berthelot, V.J. Bardou, J.L. Blache

Difficult airway management in cardiac anaesthesia: the role of transillumination guided intubation A.79
A. Gille, T. Alexander

The double lumen tube. Indications, application, monitoring (A video film) A.80
K. Wiedemann, U. Klein, H.D. Becker, R Gottschall

Intubatin laryngeal mask airway (Fastrach®)· the learning curve of its use A.81
N. Palgimesi, A. Bairaktari

How to choose the adequate size of a left-sided double-lumen endobronchial tube. An assessment of the radiographic Brodsky's method . A.82.
M. Landi, X. Baron, H. Lanquetot, J. Fusciardi

10:45–12:15 Tuesday 28 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

A new modality of high-frequency ventilation· superposition of two jet streams A.83
G. Ihra, A. Kepka, P Krainck, C. Schabernig, A Aloy

A new prototype of an electronic jet ventilator and its humidification system A.84
P. Krainck, A. Kepka, C. Schabernig, G. Ihra, A. Aloy

Carbon dioxide absorption without strong alkali A.85
C.W. Renfrew, J.M. Murray, J.P.H. Fee

Carbon monoxide production in rebreathing circuits: the halogenated concentration effect A.86
C. Bonome, J. Belda, F. Refojo, M. Soro, C. Gotti, H. Aymerich

Carboxyhaemoglobin concentrations in patients during desflurane anaesthesia using a circle circuit with partially dried soda lime A.87
M. Soro, F.J. Belda, A Cortes-Uribe, F Alvarez, C. Bonome

Sodium hydroxide is a factor in the production of carbon monoxide when dried soda lime is exposed to desflurane, enflurane and isoflurane A.88
C.W. Renfrew, J.M. Murray, J.P.H Fee

Effect of using dry carbon dioxide absorbent in a rebreathing anaesthesia circuit for sevoflurane A.89
S. Chang, K. Cromack, D. Grabenkort, V. Lafita, D. Pecosky, R. Raph, M. Richardson, V. Rubinshteyn, M Stramaglia

Dry soda lime heavily degrades sevoflurane during inhalation induction A.90
W. Funk, M. Gruber, K. Taeger, J Hobbhahn

Sevoflurane is not degraded during *in vitro* low-flow anaesthesia using a sodium hydroxide-free absorbent A.91
C.W. Renfrew, J.M. Murray, J.P.H. Fee

Xenon anaesthesia in humans· expenditure and recycling A.92
A. Ferrari, F. Giunta

16:15–17:45 Tuesday 28 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

Comparison of isoflurane-clonidine, desflurane-clonidine and sevoflurane-clonidine association in middle ear surgery A.93
S. Aunac, P.E. Pendeville, P. Gourdange, M.J. Van Boven

Influence of somatometric parameters on anaesthesia cost A.94
F. Kanakoudis, S. Foka, S. Spathopoulou, A. Petru

Elimination of isoflurane, desflurane and sevoflurane after prolonged anaesthesia . . . A 95
N. Molins, A Pensado, P. Rdma, A. Vázquez-Fidalgo, S. Garrido, P Pose

Recovery from anaesthesia with sevoflurane in comparison with isoflurane in elderly patients . . . A 96
S.E Gaßmayr, R L Moser, H. Voit, W. Kroll, W.F. List

Relationship between time of exposure to desflurane, sevoflurane or isoflurane and recovery times in surgical patients . . . A 97
P Rama, N. Molins, A. Pensado, H Aymerich, C. Fernández-Goti, C. Rodríguez-Valdés

Emesis and headache after (MAC) in N_2O of halothane, enflurane and isoflurane· outcome following ENT and eye surgery . . . A.98
A A. van den Berg, N.M. Honjol, C.R. Rozario, T Mphanza, A. Rizk, B. Udom

Sevoflurane and propofol in surgical patients comparison of emergence time and psychomotor function . . . A 99
A. Pensado, P. Rama, N Molins, M.L. Dávila, S. Rodiño, M Fraga

Cognitive recovery after carotid endarterectomy: a comparison of isoflurane *vs* desflurane or sevoflurane anaesthesia . . . A 100
V. Umbrain, J. Keeris, J. D'Haese, E. De Roover, F Camu

Quality and time of recovery from longlasting desflurane or isoflurane anaesthesia . . . A 101
A. Pensado, P Rama, N Molins, A Figueira, J Muñiz

Sevoflurane is comparable to propofol for the insertion of laryngeal mask airway in adults . . . A.102
L.K Ti, M.Y.H. Chow

10:45–12:15 Monday 27 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

PCCO monitoring during major surgery . . . A 103
G. Della Rocca, C. Montecchi, C. Coccia, F. Pugliese, L Pompei, F. Ruberto, F Musolino, P. Di Marco, A. Gasparetto

Evaluation of PCCO during lung transplantation . . . A.104
G. Del Rocca, C. Montecchi, C. Coccia, F. Pugliese, L. Pompei, F. Ruberto, M.G. Costa, M. Antonini, A Gasparetto

Continuous cardiac output. agreement with bolus thermodilution method . . . A.105
J.G. Martín Hernández, T Carnero Carnero, M.M. Orts Rodriguez, C. Pérez Hernández, J Lorenzana, F. Gilsanz

Clinical implications of continuous automated thermal cardiac output measurement in abdominal aortic surgery . . . A 106
B. Grosomanidis, N. Tsotsolis, E. Papanastasiou, D. Setzis, A. Efthimiou, C. Skourtis

Continuous *vs* intermittent thermodilution cardiac output after cardiopulmonary bypass . . . A 107
A. Mallick, B. Barry, M. Vucevic, A R Bodenham

Continuous cardiac output and mixed venous oxygen saturation monitoring during cardiac anaesthesia . . . A 108
A Herrera, S. Amezcua, F. Marin, A. Merina, C Suan

Comparing methods of cardiac output measurement: oesophageal Doppler *vs* thermodilution . . . A.109
T. Delgado González, S. García del Valle, S. Gonzáles Fernández, B. López López

Non-invasive haemodynamic monitoring: oesophageal Doppler *vs* thermodilution in cardiac surgery . . . A.110
A. Toral, M.J Martín, C. Bonome, S. Garrido, E. Rodriguez

Improved safety during labetalol-induced hypotension by using an oesophageal Doppler for continuous monitoring of cardiac output . . . A 111
M Papageorgiou, I. Zevla, A. Dimakopoulou

Intraoperative control of the efficiency of thoracic sympathectomy for palmar hyperhidrosis by monitoring width pulse waveform and temperature . . . A 112
M.J Jiménez, G. Fita, I. Rovira, G. Martínez, M.A Callejas, X. Baldó

13.00–14.30 Saturday 25 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (ORAL SESSION)

Premedication with clonidine for laparoscopic cholecystectomy . . . A 113
J. Málek, J Knor, A Kurzová, M Lopourová

Effects of age and gender on the optimal administration dose of intramuscular midazolam premedication . . . A.114
T. Nishiyama, K. Hanaoka

Effect of midazolam premedication on implicit memory activation during alfentanil-nitrous oxide-halothane anaesthesia . . . A 115
F. Ulus, G. Ozmert, N Kadıoğulları

Awareness during anaesthesia in patients undergoing cardiac surgery . . . A 116
L. Qvist, L Algotsson

Need for oxygen supply for patients' transfer from the surgical room to the post-anaesthesia care unit . . . A 117
T Saz, G. Aguilar, J. Solliveres, C. Reina, J V. Llau, F.J Belda

Oculocardiac reflex· is it relevant? . . . A 118
Á Bognár, T. Török, Z. Gingl, A. Kardos, L Kolozsvári, L Rudas

8:30–10:00 Sunday 26 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (ORAL SESSION)

Is there a correlation between postoperative vomiting and increased extraocular muscle tone in strabismus surgery? . . . A.119
T. Papenfuss, C.C. Apfel, W.D. Schafer, P Kranke, C. Goepfert, P. Sefrin, N. Roewer

Decisional algorithms for target-controlled infusion of propofol in digestive endoscopy A.120
P. Pandin, F. Degroote, P. Vanderlinden, A. Haché, F Cantraine, L Barvais, A. d'Hollander

Perioperative stress under different regimens of propofol and sufentanil for 'Fast-track'-anaesthesia in cardiac surgery A.121
T. Uhlig, G. Neumann, A. Pietsch, M. Hüppe, H Kuppe, P. Schmucker

Balanced anaesthesia with remifentanil and propofol; a simplified administration protocol A.122
F.E.A. Geisler, M.P. Boldin, J.F.A. Blommerde

Remifentanil or fentanyl for carotid artery surgery A.123
W. Wilhelm, J. Harrer, N Schlaich, T. Ziegenfuß, M Müller, R. Larsen

TIVA without narcotics for anaesthesia under field conditions: interest of ketamine A.124
L. Bargues, Y. Auroy, F Servin, B. Lenoir

14:00–15:30 Sunday 26 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (ORAL SESSION)

Bispectral index: a decision or a problem of an estimation of anaesthesia depth? A.125
V. Soubbotin, V. Vinogradov, O. Petrov, S. Juravel, V. Lickvantzev, V Smirnova

Informational saturation of EEG *vs* bispectral index of EEG A.126
V. Lickvantzev, O. Petrov, A. Sitnikov, V. Soubbotin, L Kalinkin

Bispectral EEG monitoring of deep breath inhalation induction of anaesthesia with sevoflurane A.127
R Vermeulen, C De Deyne, M. Struys, B Claessens, G. Vundelinckx, E Vandermeersch, R. Heylen

Patient-tailored sevoflurane anaesthesia guided by bispectral EEG A.128
H. Keyer, C. De Deyne, M. Struys, K Vissers, R. De Jongh, L. Merckx, E. Vandermeersch, R. Heylen

Clonidine pretreatment does not reduce anaesthetic requirements in bispectral EEG-guided sevoflurane anaesthesia A.129
M. Vanderlaenen, C. De Deyne, M. Struys, H. Keyer, P. Van Leuven, J Van Canneyt, L Buyse, R. De Jongh, E. Vandermeersch, R Heylen

Bispectral index and calculated plasma concentrations of propofol and sufentanil during emergence from target-controlled anaesthesia . . . A.130
P. Hans, B Hubert, J.F. Brichant, P.Y. Dewandre, W. Dewé, A. Albert, V. Bonhomme, M. Lamy

8:30–10:00 Monday 27 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (ORAL SESSION)

Variations of bispectral index during peroperative movements and recovery from isoflurane anaesthesia A.131
B. Guignard, C Menigaux, C. Coste, M Chauvin

Dose-response relationship between target-controlled concentration of propofol and bispectral index A.132
M. Malinge, F. Petitfaux, J.Y. Lepage, J.M. Malinovsky, A. Cozian, M. Pinaud

Matching sympathetic response of visceral pain with propofol target-controlled infusion: a blinded bispectral study A.133
P. Pandin, F. Degroote, P. Vanderlinden, F. Cantraine, L Barvais, A. d'Hollander

Improved anaesthetic titration using the bispectral index of the EEG in malignant obese patients A.134
M. Verlaeckt, C. De Deyne, M. Struys, K. Vissers, R. De Jongh, L Buyse, E. Vandermeersch, R. Heylen

Bispectral index of EEG does not predict haemodynamic responses to laryngoscopy and intubation under sevoflurane anaesthesia A.135
P. Van Leuven, C. De Deyne, M. Struys, R De Jongh, M. Cauberghs, G. Goossens, H. Adriaensen, R. Heylen

Comparison of SEF and BIS by using two devices for electroencephalography under different regimens of induction of anaesthesia in cardiac surgery A.136
T. Uhlig, A. Schöffel, H. Adams, M. Huppe, H. Kuppe, P. Schmucker

14:00–15:30 Monday 27 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (ORAL SESSION)

Who or which predicts anaesthetic depth better – the bispectral index of the EEG, pupillary responses to light or anaesthesiology residents? . A.137
C. Sitzwohl, M. Winkler, P. Nagele, A Bacher, A. Blaicher, T. Weber, D I. Sessler

Transcranial near infrared spectroscopy and EEG during cardiopulmonary bypass A.138
P. Durak, J. Şenyurt, Ö Erdemli, S Ebil

Comparative study of the TOF ratio measured by the TOF guard with and without thumb repositioning. A.139
K. Pelgrims, B.F. Vanacker, E. Vandermeersch

Comparative study of the TOF ratio measured by the ParaGraph *vs* the TOF guard A.140
K. Pelgrims, B.F. Vanacker, E Vandermeersch

An alternative to adductor pollicis muscle in monitoring neuromuscular function. flexor hallucis brevis muscle A.141
H. Hepağuşlar, A Onal, F. Övül

Computer-controlled infusion of non-depolarising muscle relaxants using an adaptive neural network A.142
G Geldner, U. Schwarz, J Romeiser, M. Lendl, M. Georgieff

16:15–17:45 Monday 27 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

C7E3-modified thromboelastography predicts plasma fibrinogen concentrations in cardiac patients A.143
O.P. Panzer, S C Kettner, S A. Kozek, F.A. Seibt, J. Kofler, B. Stoiser, G.J. Locker, M. Zimpfer

Cross-sectional area of the internal jugular veins ultrasound comparison between sides and correlation with anthropometric parameters A 144
G R de Oliveira Filho, C.R de Oliveira

Percutaneous catheterization of the internal jugular vein· original approach A.145
P Stevanović, M Kaludjerović, M. Plazinčić

Factors affecting guide wire position during central venous catheter placement A 146
H.A McLure, J. Filshie, R. Craig

When must we stop subclavian vein cannulation attempts? A 147
J.-Y. Lefrant, L. Muller, J-L. Pandolfi, S. Bouges, G. Saïssi, J-J Eledjam

Knowledge about pulse oximetry among residents and nurses A 148
H Bilgin, O. Kutlay, D Cevheroğlu, G. Korfalı

The advantage of preadmission anaesthesia consultation: results of a randomized controlled study A 149
M. Blanc-Jouvan, D Long, A. Mercatello, M P Benoit, M Khadraoui, R. Chacornac, C. Némoz, M Gaydarova, J.P Boissel, J F Moskovtchenko

Evaluation of the degree of knowledge about difficult intubation A 150
P Avarguès, A M Cros, R Shehata, V. Daucourt, P Michel

Difficult intubation evaluation of the impact of the French expert conference A 151
P. Avarguès, A.M Cros, R. Shehata, P Maurette

16:15–17:45 Sunday 26 April 1998 — Room "B"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

Physical treatment of fever A.152
R Lenhardt, C H. Negishi, Jin-Soo Kim, D.I. Sessler

Influence of paralysis on the development of fever during isoflurane anaesthesia A 153
C H Negishi, R Lenhardt, J -S. Kim, D.I Sessler

Comparative study of tympanic, bladder, oesophageal and pulmonary artery temperature measurement during major abdominal surgery A.154
J.M. Budd, A. Helmy, J.W Freeman

Preservation of heat and humidity after 48 hours use of one hygroscopic heat and moisture exchanger A 155
L Thomachot, C. Boisson, F. Michelet, R. Vialet, S Arnaud, C. Martin

Effect of humidification on the incidence of adverse airway events during deepening of anaesthesia with desflurane. A.156
J.E. Hall, A.R Wilkes, E. Wright, S. Grundler

Failure of warmed insufflation gas to prevent hypothermia during laparoscopic hysterectomies A.157
K Nelskyla, A. Yli-Hankala, J Sjoberg, K. Korttila

Comparison of four forced-air blankets for intraoperative cutaneous warming A.158
Y. Camus, E Delva, Z. Abdelhalim, A. Lienhart

Tissue thickness shift detection by a new miniature ultrasound device in anaesthetic practice A 159
W Eichler, J Schumacher, R. Vogel, K -F Klotz

Tissue thickness shift detection by a new miniature ultrasound device during the perioperative period of healthy surgical patients A.160
J. Schumacher, A. Engelke, W. Eichler, S. Hagelberg, K.-F. Klotz

15:00–16:30 Saturday 25 April 1998 — Room "A"
PATIENT SAFETY, EQUIPMENT, MONITORING AND COMPUTERS (POSTER SESSION)

Anxiety does not alter gastric emptying A 161
A. Lydon, J. McGinley, P.F Duggan, G. Shorten

Laparoscopic surgery of gastro-oesophageal reflux: ECG and enzymatic study A 162
G. Boccara, W. Mamoud, C. Mann, Y. Pouzeratte, P Colson

Effect of cricoid pressure on gastro-oesophageal reflux A.163
H. Skinner, K. Girling, N. Bedforth, R. Mahajan

Capnography monitoring in non-intubated patients during recovery from anaesthesia A.164
A. Herrera, C. Suan, S. Amezcua, M C Perez-Torres, J C Luis, M de las Mulas

Evaluation of a new colorimetric ETCO$_2$-detector (Colibri) for confirmation of adequate lung ventilation A 165
J. Kofler, A. Nikolic, C.G Krenn, R. Hofbauer, P. Krafft, M. Frass

Are colorimetric carbon dioxide detectors reliable over longer periods? A.166
I. Corrigan, A Larsson

Ethanol absorption during operative hysteroscopy A.167
T. Grau, R. Conradi, E. Martin

Effects of rapid blood administration on arterial blood gases continuously monitored A.168
G. Vretzakis, E. Matsaridou, G. Vassiliadou, S Koutsias, E. Ferdi, G. Vlachogianni, D. Papadimitriou

Prediction of plasma fibrinogen concentration with native and activated thromboelastography A.169
F.A. Seibt, C. Gonano, S.C. Kettner, S.A. Kozek, O.P. Panzer, C. Weinstabl, M Zimpfer

Thromboelastographic coagulation changes after 6% hetastarch administration for the treatment of perioperative hypovolaemia A.170
T.J. Gan, I.J. Welsby, D. Kucmeroski, M Mythen, P S A. Glass

10:45–12:15 Sunday 26 April 1998 — Room "C"
CIRCULATION (POSTER SESSION)

Clinical implications of portopulmonary hypertension in liver transplant patients A.171
R. Adàlia, P. Taurà, G. Martínez-Pallí, E. Zavala, A. Alarcon, J. Gracia

Mixed venous oxygen saturation. evolution and correlations during liver transplantation .... A 172
A. Mora, J Roigé, C. Cortés, M Noguer, C Bosch, V.A. Gancedo

Endoluminal laser-Doppler measurements of jejunal mucosal perfusion in patients undergoing liver transplantation .... A 173
E. Rønholm, L Backman, S Friman, K L Karlsen, L Mjornsted, M. Olausson, A. Åneman

Xanthine oxidase is directly associated with liver ischaemia-reperfusion-induced remote myocardial dysfunction A.174
A.A Weinbroum, V. Rudick, E. Hochhauser, Y Kluger, B.A. Vidne

Effects of positive end-expiratory pressure on indices of left ventricular diastolic function during laparoscopy A.175
L Dumont, V. Picard, C. Mardirosoff, C Dumont, M Mattys, J. Massaut

Haemodynamic and catecholamine responses to a rapid increase in sevoflurane or isoflurane concentration A.176
T. Nishiyama, K. Hanaoka

Which parameters unmask diastolic dysfunction in hypertensives during Valsalva manoeuvre as measured with Doppler sonography? .. A.177
G. Schuepfer, M Zuber, C Konrad, C Fankhauser, P Erne

Effect of the insufflating gas on the release of vasopressin during laparoscopy in pigs A.178
C Mann, G Boccara, Y. Pouzeratte, F Navarro, D Bichet, P Colson

13.00–14.30 Saturday 25 April 1998 — Room "C"
CIRCULATION (ORAL SESSION)

Comparison of gastric-to-arterial ($P(\text{r-a})_{\text{CO}_2}$) and gastric-to-end tidal ($P(\text{r-et})_{\text{CO}_2}$) P_{CO_2} gap after cardiac surgery A.179
G. Lebuffe, C. Decoene, A Pol, B. Vallet

Gastric mucosal hypoperfusion during cardiopulmonary bypass is associated with increased postoperative cardiovascular morbidity...... A.180
J C. Sicsic, H. Corbineau, V. Louvard, M Sellin, J. Duranteau, A. Leguerrier, Y. Logeais, C. Ecoffey

Increased gastric-to-arterial P_{CO_2} gap ($P(\text{r-a})_{\text{CO}_2}$) predicts occurrence of circulatory failure after cardiac surgery A.181
G. Lebuffe, C. Decoene, A Pol, B. Vallet

Systemic and regional tissue perfusion in response to increasing metabolic demands after cardiac surgery A.182
S.M. Jakob, E. Ruokonen, J. Takala

Can pharmacological intervention re-establish splanchnic blood flow during carbon dioxide-pneumoperitoneum? An experimental model A.183
M. Agustí, J.I. Elizalde, R. Adàlia, P Taurà, A Cifuentes, C. Gomar

Impact of ventilation with positive end-expiratory pressure on splanchnic oxygenation A.184
A. Fournell, L.A. Schwarte, T.W.L Scheeren

16:15–17:45 Sunday 26 April 1998 — Room "C"
CIRCULATION (POSTER SESSION)

Comparison of endothelial function in the internal mammary artery and the radial artery A.185
C. Huraux, K. Yamagushi, F. Szlam, J.H. Levy

Pressure-flow relationship of arterial and venous bypass grafts. influence of volume changes and pharmacological vasodilatation .... A 186
B.H. Walpoth, P. Neidhart, A. Bosshard, B Kipfer, O.M. Hess, U. Althaus, T. Carrel

Haemodynamic effects, myocardial ischaemia, and timing of extubation with TIVA propofol- sufentanil *vs* midazolam-sufentanil-isoflurane anaesthesia for CABG surgery A.187
K. Jovanovic, P. Romic, N. Filipovic, M Surbatovic

Effects of remifentanil and fentanyl on perioperative oxygen consumption in patients undergoing myocardial revascularization A.188
C. Reavley, A. Reidel, S. von Kier, D. Royston

Myocardial protection during coronary artery bypass graft surgery with thoracic epidural analgesia A.189
F.M. Lyons, B J. Riedel, M. Haw, D. Royston

Effects of hypothermic rewarming phase during cardiopulmonary bypass on cerebral perfusion and cerebral oxygenation A.190
F Gao-Smith, D.N.F. Harris, S. Sapsed-Byrne

Effects of hypothermic rewarming phase during cardiopulmonary bypass on NSE and S-100 release and cerebral lactate production A.191
F. Gao Smith, D.N F. Harris, S. Sapsed-Byrne

Effect of dexamethasone on extravascular fluid content after cardiopulmonary bypass A.192
S. Giannaris, M. Scholz, G. Wietasch, A. Hoeft, B. Schorn

Pulmonary endothelial cytoprotection by fructose-1,6-diphosphate in cardiac surgery A.193
B. Riedel, A.W. Fox, D. Royston

Propofol inhibits myocardial lipid peroxidation during coronary artery bypass grafting surgery A.194
M. Murat Sayın, O. Özatamer, R. Taşoz, K. Kılınç, T. Neyyir Eren

8:30–10:00 Sunday 25 April 1998 — Room "C"
CIRCULATION (ORAL SESSION)

Is load dependence of rate of left ventricular relaxation coupled to contractile function in coronary surgery patients? .... A 195
S.G De Hert

Intrathoracic blood volume as a reliable cardiac preload indicator in mechanically ventilated PTS with PEEP .... A 196
G Susini, A. Tosoni, M. Tullii, G.F Manfredi, R. Panzeri, E Villa, A Attanasio

Haemodynamic effects of an agonist of the vasopressin system for treatment of refractory hypotension at anaesthetic induction in patients on chronic ACEI-therapy. preliminary results .... A 197
D. Eyraud, S. Brabant, N Dieudonné, M H Fléron, M. Bertrand, S. Mouren, P Coriat

A prospective, randomized comparison of haemodynamic behaviour and treated haemodynamic side effects during remifentanil/ propofol/ oxygen, remifentanil/desflurane/oxygen, remifentanil/sevoflurane/oxygen and alfentanil/ isoflurane/nitrous oxide anaesthesia for ENT surgery .... A 198
T. Loop, H.-J. Priebe

Veno (inf. *vena cava*) – arterial carbon dioxide difference during clamping for surgery of the abdominal aorta A.199
G. Vretzakis, D. Papadimitriou, G. Papadopoulos, M Fatouros, V. Zervas, E. Ferdi, G. Vassiliadou, E. Kaprini

Cardiovascular and catecholamine responses to endovascular abdominal aortic aneurysm repair A.200
J.P. Thompson, J.R. Boyle, M.M Thompson, P.R.F. Bell, G. Smith

10:45–12:15 Monday 27 April 1998 — Room "C"
CIRCULATION (POSTER SESSION)

Effects of dobutamine on haemodynamic changes during surgical procedures performed in the genupectoral position. An echo-Doppler study .... A 201
G. Galimberti, G. Berlot, R. Muchada, A Gullo

Is load dependence of left ventricular relaxation influenced by β-adrenergic tone in coronary surgery patients? .... A 202
S.G. De Hert

A second post-induction dose of propofol does not attenuate the haemodynamic responses to intubation .... A 203
D Savva

Minimum dose of esmolol which attenuates the chronotropic response to intubation .... A 204
D. Savva

Effects of halothane, isoflurane anaesthesia and magnesium infusion on heart rate variability .... A 205
T.S. Çeliker, C. Çeliker, S. Küçukay, K. Pembeci, M. Tuğrul, F. Korkut

Heart rate variability: monitoring of autonomic nervous system activity during general anaesthesia A.206
W. Plazak, T. Muszyński, A Macheta, H Podziorny, J. Łach, P. Podolec, K Potocka-Plazak, J Andres

Effect of sandostatin on heart rate variability during anaesthesia and surgery A.207
A. Petru, G Kochiadakis, F Kanakoudis, D Michaloudis

Autoregulation of inner ear blood flow during propofol and isoflurane anaesthesia in middle ear surgery .... A 208
M P Preckel, C. Ferber-Viart, C Dubreuil, R. Duclaux, C S Degoutte, J.C Granry, V. Banssillon

Descending limb of the Frank-Starling curve: reality or myth? A.209
S.G. De Hert

A comparison of the effects on heart rate and blood pressure during and after anaesthesia with induced hypotension using glyceryl trinitrate alone or labetalol alone A.210
A A. van den Berg

14:00–15:30 Sunday 26 April 1998 — Room "C"
CIRCULATION (ORAL SESSION)

Influence of dantrolene sodium on myocardial reperfusion injury after regional ischaemia in the rabbit heart *in vivo* A.211
B. Preckel, T. Comfère, V. Thàmer, W. Schlack

Effect of propofol on reperfusion injury in the isolated rat heart A.212
D Ebel, T. Comfère, B. Preckel, V Thämer, W. Schlack

Influence of inhalational anaesthetics on myocardial reperfusion injury after cardioplegic arrest in the isolated rat heart A.213
B. Preckel, V. Thämer, W. Schlack

Hyperoxic lung injury and lung free radical metabolism in rats; the effects of N-acetylcysteine A.214
P Durak, G.Ozgen, A. Ayyıldız, S. Müftüoğlu, S. Kultufan, E. Aşan, O. Canbolat, S Ebil

Effects of isoflurane and halothane on hepatic blood flow and sinusoidal microcirculation in the presence of hypoxia A.215
K.-F Klotz, C Tsunoda, R. Nakagawa, K. Wagner

Tissue of oxygen extraction during ketamine anaesthesia in dogs: effects of sympathetic blockade A.216
P. Van der Linden, D. Schmartz, F. De Groote, N. Mathieu, H. Zang

14:00–15:30 Monday 27 April 1998 — Room "C"
CIRCULATION (ORAL SESSION)

Depressive effect of alfentanil on isolated human atrial muscle A.217
S. Ünver, K. Derici, S. Ebil, E.D. Yılmaz

Effects of midazolam and flumazenil in isolated rabbit hearts A.218
T. Ozturk, Y. Tuncok, H Guven, S Kalkan, G. Aran

Myocardial effects of desflurane in hamsters with cardiomyopathy A.219
B. Vivien, J.L Hanouz, P. Coriat, B. Riou

Ischaemic preconditioning and tissue noradrenaline concentration in the rat heart A.220
K Dote, N. Adachi, T. Yorozuya, Y Takasaki, S. Tsubota, T. Fujitani, T. Arai

Effects of hypertonic sodium solution in rat and rabbit myocardium: a mechanical and electrophysiological study A.221
P. Ruel, M.-P. Sauviat, B. Riou, Y. Lecarpentier, P. Coriat

Acute potassium ion replenishment normalizes arrhythmia rate in chronic hypokalaemic rats *in vitro* A.222
M. Anetseder, G. Mohiuddin, D.J. Miletich, N. Roewer

16:15–17:45 Monday 27 April 1998 — Room "C"
CIRCULATION (POSTER SESSION)

Haemodynamic effects of inhaled nitric oxide and intravenous milrinone in cardiac surgical patients with pulmonary hypertension A.223
I Rovira, G. Fita, M Pacheco, P. Matute, M. Basora, A. Faulí, C. Roux, C. Gomar

Demographic data of responders and non-responders to inhaled nitric oxide among patients with mitral valve stenosis A.224
P. Knapik, M. Zembala, J. Puzio, M. Knapik, G Juszczyk

Expression of endothelin receptors in the pulmonary circulation A.225
J. Schmeck, S. Schmeck, A. Heller, K. van Ackern, T. Koch

Effects of endothelin-1 in the pulmonary circulation A.226
J. Schmeck, S. Schmeck, A. Heller, K. van Ackern, T. Koch

Effect of halogenated and intravenous anaesthesia on hypoxic pulmonary vasoconstriction and cyclo-oxygenase and nitricoxide-synthase blockade A.227
P. Ewalenko, S. Brimioulle, S. Deneu, S. Pierre, R. Naeije

Pulmonary vascular tone does not affect central blood volume .... A 228
T.W.L. Scheeren, G. Wietasch, J.O. Arndt

Carbon dioxide reactivity in patients with sleep apnoea syndrome. a transcranial Doppler study A.229
A.B. Ahmed, R.P. Mahajan

Packed cell volume variations in a rabbit model of arterial thrombosis and bleeding A.230
B. Ouaknine-Orlando, C.M. Samama, B. Riou, P. Coriat

Intraoperative haemodynamic changes during open and laparoscopic adrenalectomy for phaeochromocytoma A.231
D. Bernard, Y Ozier, N. Jude, Y Chapuis, C Conseiller

15:00–16:30 Saturday 25 April 1998 — Room "C"
RESPIRATION (POSTER SESSION)

Gas exchange and intrapulmonary shunting during liver transplant .... A 232
G. Martínez-Pallí, J. Balust, J. Beltran, E. Zavala, M.T. Anglada, P. Taurà, J. Visa, J.A. Barberà, R. Rodriguez-Roisin

Abrogation of pulmonary dysfunction induced by liver ischaemia-reperfusion role of circulating xanthine oxidase A.233
A.A. Weinbroum, Y. Kluger, E. Karchevski, V. Rudick

Re-expansion of atelectasis during general anaesthesia. A study using computed tomography .... A 234
H.U. Rothen, P. Neumann, J.E. Berglund, J. Valtysson, A. Magnusson, G. Hedenstierna

Vital capacity manoeuvres after cardiopulmonary bypass. Effects on lung function in a pig model A.235
L. Magnusson, H. Tydén, G. Hedenstierna

Does the prone position improve arterial oxygenation during non-invasive positive inspiratory pressure ventilation? A.236
A. Eremenko, D. Levikov, V. Egorov

Effects of reverse Trendelenburg on compliance and oxygenation indices in obese surgical patients A.237
C. Modesti, L. Sollazzi, V. Perilli, S. Riccardi, R. Ranieri

Effects of fentanyl and alfentanil on breathing pattern during halogenated anaesthesia A.238
J. Canet, P. Vila, J. Giner, R.G Guasch, J. Sanchis, F. Vidal

Comparative effects of halothane and isoflurane on ventilation A.239
J. Canet, P. Vila, J Sanchis, J. Giner

Acute respiratory failure in patients after surgical thoracic oesophagectomy A.240
E. Zavala, F.X. González, L Sabater, R. Rull, M.A. López-Boado, N. Fábregas, G. Martinez, A. Alcón

10:45–12:15 Sunday 27 April 1998 — Room "D"
RESPIRATION (POSTER SESSION)

Pulmonary gas exchange during hyperthermia A.241
M. Deja, T Kerner, O. Ahlers, J. Loffel, H Riess, P Wust, D. Pappert, H Gerlach

Pressure-controlled ventilation *vs* volume-controlled ventilation during general anaesthesia with peroperative respiratory system dynamic compliance changes .... A 243
N Vialles, X Capdevila, E. André, P Biboulet, C. Plasse, F. d'Athis

Pressure-controlled ventilation with a laryngeal mask airway during general anaesthesia .... A 244
E André, X Capdevila, N. Vialles, P. Biboulet, C Plasse, F d'Athis

Influence of tracheal stenosis on high frequency jet ventilation a model study .... A 245
M. Dejonckheere, D Verbessem, A d'Hollander

High-frequency ventilation techniques improve oxygenation in patients with impaired pulmonary function .... A 246
G. Ihra, A. Kepka, C. Schabernig, P. Kraincuk, A Aloy

Alveolar pressure measurement in patients with acute lung injury (ALI) A.247
S. Sondergaard, S. Kárason, S. Lundin, O. Stenqvist

Comparison of expiratory washout and optimized conventional mechanical ventilation during permissive hypercapnia .... A 248
J. Richecoeur, S. Vieira, Q Lu, L. Puybasset, P Kalfon, P Coriat, J J. Rouby

Effectiveness of total and partial expiratory washout in permissive hypercapnia .... A 249
J. Richecoeur, Q. Lu, S Vieira, L Puybasset, P. Kalfon, P. Coriat, J.J. Rouby

8:30–10:00 Sunday 26 April 1998 — Room "D"
RESPIRATION (ORAL SESSION)

Effect of pipecuronium in isolated human bronchi A.250
L Zappi, S. Ping-Fang, S. Nicosia, F. Nicosia, K. Rehder

Comparative effects of nitric oxide, enflurane and isoflurane on respiratory resistance with methacholine-induced bronchoconstriction A.251
J.Y Sim, K.S. Hwang, I C. Choi, P.H. Park

Inhaled nitric oxide improves ventilation/perfusion relationship after anoxic ischaemia and reperfusion in isolated rabbit lungs .... A 252
G. Hermle, H. Schutte, W. Seeger, K Geiger

Effects of inhaled nitric oxide, L-NAME and the association of both in an experimental model of one-lung ventilation A.253
A. López, I. Rovira, G. Fita, E Carrero, S. Herrero

Role of endogenous nitric oxide in the adaptation of the pulmonary arterial bed to one-lung ventilation during thoracic surgery .... A 254
E del Barrio, G. Varela, P.G. Cosmes, M Jiménez, C. Muriel

10:45–12:15 Monday 27 April 1998 — Room "D"
RESPIRATION (POSTER SESSION)

Effects of thoracoscopy on the immediate postoperative pulmonary function .... A 255
C Karler, G. Bardoczky, M. Cappello, A. d'Hollander

Abdominal wall retractor technique *vs* pneumoperitoneum laparoscopic surgery. Implications for anaesthetics A.256
C. Vivo, T. Gallen, J. Zuriaga, M. Carrau, J Escrig, M Vila

Oxygen homeostasis during laparoscopic procedures in morbidly obese patients A.257
A Muregancuro, L Dumont, C Mardirosoff, M. Mattys, V. Picard, J Massaut

Effect of pneumoperitoneum on *Va/Q* in laparoscopic cholecystectomy patients A.258
L Andersson, L. Lagerstrand, A. Sollevi, L -Å. Brodin, S Odeberg-Wernerman

Estimating pulmonary shunt fraction in hypercapnic patients using a physiology simulator A.259
J G. Hardman, N M Bedforth, R P. Mahajan, A R. Aitkenhead

Use of a model of gas exchange to infer hypoxaemia in patients with impaired *V/Q* .... A 260
S. Snape, S Bakewell, J.G. Jones

Assessment of regional ventilation and determination of time constants in ARDS using dynamic multiscan computed tomography A.261
H U Kauczor, K. Markstaller, N. Weiler, B. Eberle, W. Heinrichs, M. Thelen

Measurement of regional alveolar oxygen partial pressure by helium-3 magnetic resonance imaging of the lung A.262
K Markstaller, B. Eberle, H.-U Kauczor, N Weiler, R. Surkau, W. Schreiber, W. Heinrichs, M. Thelen

A comparison of three methods for measuring thoracopulmonary P-V curves in patients with acute respiratory failure A.263
Q Lu, S. Vieira, J. Richecoeur, L Puybasset, P. Coriat, J J. Rouby

13.00–14.30 Saturday 25 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (ORAL SESSION)

Effect of overnight sedation with lorazepam on preoperative stress in cardiac surgery .... A 264
C J. Gilhooly, K.S James, N.B. Scott

Cytokines and corticoadrenal response in elective coronary artery bypass grafting and heart transplantation .... A 265
G. Marco, M J. Sánchez, R. Calderón, R. Pérez-Reiner, F Carrascosa, P. Monedero, I Olavide, J.L Arroyo

Postoperative plasma concentrations of procalcitonin and C-reactive protein after cardiothoracic surgery with and without extracorporeal circulation A.266
M Meisner, K. Tschaikowsky, A. Hutzler, J. Schmidt, F. Harig, J. von der Emde

Increased von Willebrand factor after low molecular weight hydroxyethyl starch priming solution in cardiopulmonary bypass . . . . A 267
W van Oeveren, A. Hagenaars, I. Tigchelaar, W. Siemons, R.C.G.G Huet

Blood transfusion and coagulation after autologous platelet-poor plasma transfusion in CABG patients . . . . . . A 268
E. Kafer, S. Schwarz, H Jellinek, R.D Fitzgerald

Reduction of blood utilization in cardiac surgery . . . . . . A 269
J C Catalá, J LLagunes, E. Mateo, P Marin, J.J. Peña, E Febré, I. Marqués, F. Aguar

14:00–15:30 Sunday 26 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (ORAL SESSION)

High dose aprotinin in complex total hip arthroplasty . . . . . . A 270
M.A. García-Enguita, J.P. Ortega, C. Gómez, S. Rasal, A Pascual, A Urieta-Solanas

Aprotinin administration reduces blood loss and transfusion requirements in patients undergoing total hip arthroplasty . . . . . . A 271
J.V. Llau, G. Aguilar, J Solliveres, M F Minguez, T Saz, F.J. Belda

Use of high-dose aprotinin during spinal surgery results in a reduction in both blood loss and the amount of blood transfused . . . . . . A 272
C Fejér, M. Mezofi, P.-Pál Varga

Blood loss reduction with aprotinin during spinal instrumented surgery A.273
R M Tommasi, M. Granell, R. García-Aguado, F. Petrini, F Grau, J.M. Palanca, G. Martinelli

Aprotinin: prevalence and predictive factors for the presence of specific antibodies A study of 520 cardiosurgical patients A.274
A.M Scheule, W. Beierlein, S. Arnold, H.P Wendel, F.S Eckstein, G Ziemer

Influence of aprotinin in the proinflammatory cytokine response to elective cardiopulmonary bypass A.275
M.J. Sánchez-Ledesma, G. Marco, A Panadero, J.I. Fernandez-Liesa, M J Iribarren, P. Monedero, F. Carrascosa

8:30–10:00 Tuesday 28 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (ORAL SESSION)

Perflubron emulsion delays blood transfusions in orthopaedic surgery . . . . . . A 276
D.R. Spahn, R van Bremt, G Theilmeier, J P. Reibold, M. Welte, C. Dunger-Baldauf, H. Heinzerling, P Keipert, K Messmer

Effect of acute normovolaemic haemodilution on allogenic blood transfusion during cardiac surgery· a meta-analysis A.277
P G. Loubser, I De Juan

Pre-autologous blood donation: comparison of red blood cell apheresis and standard whole blood donation in total hip arthroplasty . . . . . A 278
N. Rosencher, F. Kalfon, O. Langeron, L Eyrolle, A Belbachir, G Wolmant, J.L. Beaumont, G. Fabre, C. Conseiller

Oral iron supplementation increases erythropoiesis in autologous blood donors A.279
S.-M. Kasper, H. Lazansky, C. Stark, L. Radbruch, U Börner

Postoperative blood retrieval and transfusion in total knee arthroplasty A.280
R. Asbert, E. Udina, O. Gomez, D. Moreno, H Ferrer, J. Bernal

Intraoperative autotransfusion combined with irradiation of the washed erythrocytes for tumour surgery: experience with 30 patients A.281
S. Durrer, G. Schuepfer, C. Konrad, H. Gerber

14:00–15:30 Tuesday 28 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (ORAL SESSION)

Platelet activation during and after major vascular surgery A.282
D. Thiry, I. El Alamy, M Diaby, C.M. Samama, P. Coriat

Intracellular storage of hydroxyethyl starch in human endothelial cells *in vitro* A.283
B Nohe, M. Burchard, C. Zanke, K. Unertl, H J Dieterich

Hydroxyethyl starch impairs *in vitro* coagulation A.284
T.T. Niemi, A.H. Kuitunen

Potato starch derived hydroxyethyl starch (200 000/0.5) compromises *in vitro* blood coagulation more than corn starch derived hydroxyethyl starch (200 000/0.5) A.285
M. Jamnicki, A. Zollinger, B. Seifert, D. Popovic, T. Pasch, D.R. Spahn

Preoperative hypervolaemic haemodilution with 6% low-molecular-weight hydroxyethyl starch: effect on some coagulation factors A.286
R. Cohendy, S. Kadri-Rozouki, J-J. Eledjam

Safety and tolerance of a novel formulation of hydroxyethyl starch (HES 130/0.4) in patients undergoing autologous blood donation with isovolaemic volume replacement A.287
S.-M. Kasper, A. Strömich, U. Golla, J. Wixforth

15:00–16:30 Saturday 25 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (POSTER SESSION)

Factors involved in the perioperative adrenomedullary response to open heart surgery A.288
I. Fidalgo, M.T. García-Unzueta, C Montalbán, M. Galindo, I. Del Moral, J. Casanueva, M.C Diago, J.R Berrazueta, J.A. Amado

Measurement and correction of ionized plasma magnesium during cardiopulmonary bypass A 289
N J Wilkes, T Peachey, S V Mallett

Heparinase reverses the inhibition of platelets by heparin in patients undergoing cardiopulmonary bypass A 290
S C. Kettner, S A Kozek, C Gonano, F A Seibt, O P Panzer, M Zimpfer

Hydroxyethyl starch slightly impairs measurement of troponin Ic concentrations: an *in vitro* study A 291
G Godet, S Ben Ayed, M.A Bernard, A Kenzari, C Huraux, E Kieffer, P Coriat

White cell depletion of residual blood after normothermic CPB A 292
M Fox, S Coghlan, M Jackson, B. Fabri

Generation of elevated doses of bradykinin in retransfused pleural shed blood during extracorporeal circulation causes acute decrease of peripheral vascular resistance A 293
F.S Eckstein, H P Wendel, M J. Jurmann, A M Scheule, L Hdberle, G Ziemer

Trasylol exposure and re-exposure: histamine kinetics in patients undergoing cardiac surgery A 294
M Adt, G Mayer, B. Lamparter-Schummert, W Krack, W. Lorenz

16:15–17:45 Sunday 26 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (POSTER SESSION)

Polymorphonuclear neutrophil functions and major oncological surgery A 295
D Mokart, D Francon, J P Brun, J.R Delpero, G Houvenaeghel, J L Blache

Effects of midazolam + nitrous oxide + oxygen anaesthesia and surgery on cellular immunofunction in mice A 296
E Dárdai, L Dénes

Influence of cortisol inhibition on the response of IL-6 and IL-10 to surgery A.297
M A Villanueva, C Montalbán, M T García-Unzueta, I. Del Moral, J J. López-Cordovilla, I Fidalgo, J.A Amado

Effects of pure propofol, Diprivan® and intralipid on active oxygen species produced by activated polymorphonuclear neutrophils A 299
P Hans, M Mathy-Hattert, G Deby, C Deby, M Lamy

Cellular mechanisms underlying inhibitory effect of halothane on inducible nitric oxide synthase induction evoked by interleukin-1β A 300
H. Maeda, M Ymamamoto, K Mizumoto, K Ogawa, H Iranami, Y. Hatano

Leucocyte alterations during hyperthermia A 301
O Ahlers, T Boehnke, T. Kerner, M. Deja, D Keh, J Loffel, B Hildebrandt, H Riess, P. Wust, D Pappert, H. Gerlach

Use of single cell gel electrophoresis technique to detect DNA damage in lymphocytes of patients anaesthetized with isoflurane A.302
L. Karabiyik, N Aygun, S Şardaş

In vivo and *in vitro* effects of propofol, midazolam and fentanyl on natural killer cell cytotoxicity A 303
D Işik, Z. Eti, F. Tükenmez, F.Y. Göğüş, M. Başaran

Activation of the complement system during autologous blood transfusion an *in vitro* study with different autotransfusion devices A.304
M Tylman, A Bengtsson, J.P. Bengtson, H Haljamde

16:15–17:45 Monday 27 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (POSTER SESSION)

Arterial blood gases during shivering and after treatment with meperidine, oxygen or both A 305
G.R de Oliveira Filho, L C. Utzig, S F Linhares

Xenon does not trigger malignant hyperthermia in malignant hyperthermia-susceptible pigs A 306
G Froeba, R J. Pazhur, C Baur, M Georgieff, T Marx

Central-core-like structures in a family disposed to malignant hyperthermia A 307
R. Fricker, R.E. Bittner, H.G Kress

Effects of dantrolene on rat fast (extensor digitorum longus) and slow (soleus) skeletal muscles A.308
O Langeron, S. Fratea, G. Orliaguet, C Coirault, P Coriat, B. Riou

Secretion of i.v. dantrolene into breast milk after MH therapy A 309
R. Fricker, K. Hörauf, P. Felleiter, H G. Kress

Perianaesthetic hyperglycaemic and endocrine responses to open cholecystectomy: comparison of general and combined general plus epidural anaesthesia A 310
G R. de Oliveira Filho, E. Cidral, M K Zardeh, E Maier

Metabolic acidosis and respiratory acidosis impair gastroduodenal motility in a pig model A 311
J.P Tournadre, C.H. Malbert, P Boulétreau, D Chassard

Insulin concentrations in samples from stored glucose-insulin-potassium bags A 312
G R. McAnulty, H.J. Robertshaw, G.M Hall

Parenteral nutrition supplemented with glutamine improves splanchnic blood flow in an endotoxin rat model A.313
E. Pscheidl, M Schywalsky

Preoperative nutritional assessment using the mini-nutritional assessment: a study on 419 elderly surgical patients A 314
R Cohendy, F. Arnaud-Battandier, G Tran, T. Gros, J.-M Plaze, J.-J Eledjam

10:45–12:15 Tuesday 28 April 1998 — Room "D"
TRANSFUSION AND HAEMOSTASIS (POSTER SESSION)

Is the helium laparoscopy the best approach for pheochromocytoma surgery? A.315
P. Santos, P Taurà, A. Saenz, I. Ornaque, J. Fontanals, C Gomar

Early diagnosis of postoperative complications after major oncological surgery Interest of procalcitonin A.316
D. Mokart, J.M. Forel, M. Merlin, M. Bonnet, J R Delpero, G Houvenaeghel, G. Perrin, P. Guerre-Berthelot, J L Blache

Effects of halothane on hormonal secretion of GH3 and AtT-20 clonal cell lines A.317
C Edwards, A.E. Bryant, F Lyons, W. Ali, G M. Hall

Does isoflurane or nitrous oxide induce micronuclei in human lymphocytes *in vitro*? A.318
G Wiesner, K.H. Hoerauf, K. Schroegendorfer, M Weindlmayr-Goettel, H W. Rudiger, K. Taeger

Role of dimethyl sulphoxide and methylprednisolone in the prevention of halothane hepatotoxicity A.319
B. Karamanlıoğlu, A Turan, G. Huseyin, O. Sengönül, Z Pamukçu

Relationship between the ICG elimination rate (CBlig) and the Child-Pugh score in patients undergoing orthotopic liver transplantation .. A 320
S. Acimovic, J Stark, R. Exner, C G Krenn, H. Pokorny, H Steltzer, M Zimpfer

Nitric oxide blood concentrations and haemodynamic changes during liver transplantation A.321
E. Cerutti, S. Battista, R. Romagnoli, G. Mengozzi, F Bar, F Zamboni, P Andruetto, M Salizzoni

Soluble heat shock protein (hsp 60) in plasma of liver transplant recipients. A clinical study A.322
C G. Krenn, E. Wildling, G. Schett, S Winkler, H. Pokorny, H. Steltzer

Blood salvage with "cell-saver" *vs* 100 000 dalton filtration A.323
J. Catalá, J. De Andrés, F. Grau, A Bengtsson, J.P. Bengtson

Blood saving in dorsal spondylodesis A.324
D R Jonker, R.M Castelein

15:00–16:30 Saturday 25 April 1998 — Room "E"
NEUROSCIENCES (POSTER SESSION)

Comparison of spontaneous frontal electromyography, EEG power spectrum and bispectral index for predicting emergence after propofol sedation A.325
M. Struys, L. Versichelen, E. Mortier, D Ryckaert, G. Rolly

Effects of propofol-sufentanil *vs* midazolam-sufentanil on cortical somatosensory evoked potentials during major spine surgery A.326
X. Paqueron, B. Vivien, F Lille, D. Heitz, O. Langeron, B. Riou, P Coriat

Effects of calculated plasma sufentanil concentration on the haemodynamic and the bispectral index responses to mayfield head holder application A.327
P Hans, B Hubert, J F. Brichant, P Y Dewandre, G. Byttebier, E. Coussaert, F Cantraine, M. Lamy

The differences in somatosensory evoked potentials changes and neurological deficit according to the location of temporary clips of cerebral arteries .... A 328
J -H Kim, Y -T. Nam

Effect of tramadol and fentanyl on somatosensory evoked potentials in sedated volunteers .... A 329
S Hussain, G J. Hobbs, B.R. Baxendale

Effects of propofol infusion on central conduction time during carotid endarterectomy A.330
A. Yoshino, S Nagashima, K. Kataoka, M Uchiyama

Dose-dependent suppression of motor evoked potentials by propofol A.331
C Thees, K.M. Scheufler, J Zentner, D. Gordes, U Pechstein, J. Nadstawek

The "approximate entropy" as an EEG parameter of anaesthetic depth? A.332
J. Bruhn, H. Röpcke, A. Hoeft

Burst suppression or silent EEG for maximal cerebral metabolic suppression. evidence from flow-metabolism studies A.333
P.W. Doyle, A.K. Gupta, B M. Matta

A study of adenosine treatment in experimental acute spinal cord injury. effect on arachidonic acid metabolites A.334
E.A. Akpek, E. Bulutçu, A. Alanay, P. Korkusuz, Ü. Ors, E. Acaroğlu

16:15–17:45 Sunday 26 April 1998 — Room "E"
NEUROSCIENCES (POSTER SESSION)

Comparison of sevoflurane and isoflurane on middle cerebral artery blood flow velocity A.335
A.C Quinn, J.M. Freeman, G. Parkin, E. Moss

Dynamic cerebral autoregulation during sevoflurane anaesthesia. A comparison with isoflurane A.336
A. Summors, B. Matta, A Gupta

Blood flow velocity of middle cerebral artery during mask induction of anaesthesia with high concentrations of sevoflurane in adult patients A.337
J.L Hanouz, C. Daubin, L Auvray-Lefrancois, P. Cabal, J M Derlon, J.P. Houtteville, J.L. Gérard, H. Bricard

Effect of desflurane *vs* isoflurane on intraoperative EEG in elderly patients A.338
M Solca, M. Aveni, E. Dellino, G. Veschi, R Russo

Fast-track supratentorial craniotomies. Experience of 100 patients A.339
N Sáiz-Sapena, V Vanaclocha, A Sáez-Fernández, J M. Sánchez, I Olavide, R Maña

Propofol sedation using a target controlled infusion system in patients undergoing stereotactic pallidotomy A 340
R. Valero, P. Gambús, N. Fábregas, I.F Trocóniz, E Carrero, C. Gomar

Intraoperative complications during pallidotomy for Parkinson's disease A review of 30 cases A 341
E. Carrero, R. Valero, N Fábregas, J. Rumià, F Valldeoriola

Brain mapping in assessment of the functional state of the brain A 342
V Cherniy

Activity of AST in the cerbrospinal fluid in patients with severe brain injury A 343
D. Vujadinović, N Gačić, V. Vujin, O Potparić, T Jovanović, M. Stošić

Thromboelastographic assessment of coagulation during surgery for meningioma A 344
A Babinet-Berthier, B Mebtouche, M.A. Pech-Amsellem, J. Philippon, J J. Guillosson, M. Samama, P Coriat

14:00–15:30 Monday 27 April 1998 — Room "D"
NEUROSCIENCES (ORAL SESSION)

Effect of hypertonic saline solution on increased intracranial pressure secondary to traumatic brain injury A 346
A. Domínguez-Berrot, J C. Ballesteros, E Rodríguez, S Gutiérrez, J. Collado, D Fontaneda

Cerebral arteriovenous P_{CO_2} difference as a measure of cerebral ischaemia in severe head injury A.347
E. Zavala, F.X. González, J. Ibañez, N. Fábregas, C. Balague, R. Adàlia, G. Martínez, L.A. Moreno

Correlation of changes in jugular venous oxygen saturation with tissue oxygenation in head-injured patients undergoing hyperventilation therapy A 348
A.K Gupta, M Swart, S Gupta, P Al-Rawi, P. Hutchinson, P. Kirkpatrick, B. Matta, D K Menon

CSF *vs* jugular lactates to detect ischaemia during sustained hypocapnia in head injuries Preliminary results A 349
S. Manrique, A Ausina, M.A. Poca, M de Nadal, C. Godet, J. Sahuquillo, A Garnacho

Hormonal and haemodynamic consequences of moderate hypothermia in head injured patients A.350
W Meissner, H. Fritz, B Dohrn, C Krapp, K Reinhart

Evaluation of carbon dioxide-reactivity and autoregulatory mechanisms in patients with severe head injury A 351
M. de Nadal, A Ausina, F. Munar, J. Sahuquillo, M. Báguena, A. Garnacho, V.A Gancedo

8:30–10:00 Tuesday 28 April 1998 — Room "A"
NEUROSCIENCES (ORAL SESSION)

Effect of propofol on lipid peroxidation and oedema in experimental brain injury A.352
H. Madenoğlu, A Boyacı, R K. Koç, I. Karakuçuk, M. Erşepçiler, A Akin

Oestradiol improves ischaemic neuronal damage in gerbil hippocampus A.353
N. Adachi, J Chen, K. Liu, K. Dote, T Arai

Potassium channel blockers blunt hypoxic cerebral vasodilatation in the awake dog A 354
G. Audibert, S. Ricco, A. Legris, D Hartemann, J Lambert, C.S. Saunier, M.C. Laxenaire

Imipramine chronic treatment up-regulates 5-HT_{1A} receptor in rat hippocampus membranes A.355
A. Gomez, I. Bellido, F. Sanchez de la Cuesta

Low extracellular Ca^{++}/Mg^{++} ratio opposes anaesthetic actions on old hippocampal neurones A 356
H. El-Beheiry, A Ouanounou, P L Carlen

Markers of neuronal injury during liver transplantation· a preliminary report A 357
S E Bakewell, B.F Matta, J. Klinck, K E. Gunning

13.00–14.30 Saturday 25 April 1998 — Room "E"
LOCAL AND REGIONAL ANAESTHESIA (ORAL SESSION)

Lignocaine + clonidine *vs* lignocaine + bupivacaine. comparison in peribulbar anaesthesia A 358
T. Gillart, F. Bevillard, J.M Constantin, I. Houtman, J.E Bazin, P. Schoeffler

Effect of volume and speed of injection of local anaesthetics on akinesia during peribulbar block A 359
T Gillart, G. Gindre, F. Bevillard, I Houtman, J.E Bazin, P Schoeffler

Sub-Tenon's *vs* retrobulbar anaesthesia for cataract surgery A 360
C.L.G. Rutten, K F. Tjia, M.J M. Gielen

Haematoma frequency in peribulbar anaesthesia A 361
H. Kallio, M. Paloheimo, E.-L Maunuksela

A retrospective review of 7235 consecutive regional anaesthetics for cataract surgery A.362
M. Granell, M.R Tommasi, Y. Perez, R. García-Aguado, G. Muñoz, T. Sánchez, A Rodriguez, F. Grau

14:00–15:30 Sunday 26 April 1998 — Room "E"
LOCAL AND REGIONAL ANAESTHESIA (ORAL SESSION)

Prevention of hypotension after spinal anaesthesia for elderly patients: a comparison of intravascular administration of crystalloid, colloids and no prehydration .... A 363
S. Esin Lekılı, Yasemin Karcioğlu, Işıl Eren

Cardiovascular effects of crystalloid and colloid solutions during spinal anaesthesia A.364
P Marhofer, B. Faryniak, C. Oismüller, S Kapral, N. Mayer

Effects of preloading with NaCl 0.9%, HES (450/0.7) 6% and NaCl 3% on haemodynamic changes and serum osmolality in patients undergoing TURP under spinal anaesthesia A.365
I. Karabeyoğlu, N. Göğüş, T. Gumuş, H. Gülmuş, S. Deren, Ö. Cuvaş, C. Aksu

Puncture technique and postural post-dural puncture headache A.366
H. Flaatten, T Thorsen, B Askeland, M. Finne, J Rosland, K. Rønhovde, T. Wisborg

Unilateral spinal anaesthesia. Effects of needle design A.367
A. Casati, G. Fanelli, G. Aldegheri, G.L Cappelleri, M. Berti, G. Torri

Spinal local anaesthetics distribution with two different pencil-point needles A.368
N. Vervloesem, C Mardirosoff, L. Dumont, M. Wolfs

10:45–12:15 Monday 27 April 1998 — Room "E"
LOCAL AND REGIONAL ANAESTHESIA (POSTER SESSION)

Advantage of multiple nerve stimulation in the axillary brachial plexus block .... A 369
J. Pascal, C. Michard, R. Allary, S. Molliex, C. Auboyer

Effects of surgical position on pulmonary function in patients with diaphragmatic paresis due to interscalene brachial plexus block A.370
X. Sala-Blanch, L. Edo, M. Vargas, R Masià, J. Correa

Superficial microcirculatory effects of interscalene plexus block A.371
S. Lehtipalo, L.-O D. Koskinen, J. Kolmodin, G. Johansson, B. Biber

Does a distal infection of the upper limb interfere with the success rate of axillary block? .... A 372
O Schneuwly, M. Peter, A. Forster

Cervical plexus block for carotid endarterectomy: influence of locoregional technique A.373
J C Merle, K Abhay, G. Dhonneur, J.X. Mazoit, S. Rezaiguia, P Duvaldestin

Cervical plexus block with ropivacaine for carotid endarterectomy A.374
B. Loreggian, D Ruffa, P Greco, G. Crespi, M.D. Centemeri, S. Greco, G. Servadio

Are muscle relaxants to be used in regional intravenous anaesthesia? A.375
N. Ünal, S. Poçan, I. Iltar, E. Ozgencil, Y. Keçik

Clonidine and lidocaine *vs* lidocaine for intravenous regional anaesthesia A.376
M. Gentili, J.-M. Bernard, F. Bonnet

Is ropivacaine 0.2% an alternative to lidocaine 0.5% for intravenous regional anaesthesia? A.377
P G Atanassoff, M.W.B. Hartmannsgruber

16:15–17:45 Monday 27 April 1998 — Room "E"
LOCAL AND REGIONAL ANAESTHESIA (POSTER SESSION)

Total knee replacement: a comparison of ropivacaine and bupivacaine in combined femoral and sciatic block A.378
D. McNamee, P Convery, K. Milligan

Anterior approach to sciatic nerve block, a new landmark .... A 379
I Pagani, I Pellicioli, E. Viola, P Colazzo

Continuous popliteal sciatic nerve block catheter: incidence of complications .... A 380
P. Cuvillon, P. Bruelle, E. Touabtia, V. Piffaut, J.J. Eledjam

Continuous analgesia with a femoral catheter: plexus or trunk blockade? A.381
Y. Barthelet, X. Capdevila, E. André, N. Vialles, P. Biboulet, F. d'Athis

Analgesia for total hip arthroplasty with posterior lumbar plexus block .... A 382
R. Stevens, E. Van Gessel, N. Flory, Z Gamulin

Regional anaesthesia for femoral neck fracture surgery: comparison of lumbar plexus block and spinal anaesthesia A.383
L. Eyrolle, P. Zetlaoui, A. Belbachir, N. Rosencher, Ch. Conseiller

Clinical comparison between ropivacaine and bupivacaine for lower limb peripheral nerve block A.384
P Beccaria, G. Fanelli, A. Casati, G Aldegheri, A. Leoni, E. Moizo, B. Borghi

Ultrasonographic guidance reduces the amount of local anaesthetic for 3-in-1 blocks A.385
P Marhofer, C Schrogendorfer, T. Wallner, S Kapral, N Mayer

Comparison of the "3 in 1" and "fascia iliaca compartment" blocks in adults: clinical and radiographical analysis A.386
X. Capdevila, P Biboulet, Y Barthelet, Y. Ryckwaert, F d'Athis

10:45–12:15 Tuesday 28 April 1998 — Room "E"
LOCAL AND REGIONAL ANAESTHESIA (POSTER SESSION)

Improved regional blockade prolongation method from mixture of local anaesthetics ...... A 388
J O Lim, W.Y. Baek

Peroperative analgesic effects of clonidine and fentanyl administered by systemic and/or epidural routes A.389
E. Barrera, E. Samsó, J Vallés, M M. Puig

Effects of clonidine on conductances active during post-tetanic hyperpolarization in peripheral nerve· studies of local anaesthetic action of clonidine A.390
C. Dalle, C Bretton, M. Schneider, F. Clergue, P. Jirounek

Effects and plasma concentrations of clonidine added to local anaesthetics for axillary plexus blocks .... A 391
J-M Bernard, R Delpech, D. Le Roux, P Mouton

Addition of nalbuphine to peribulbar anaesthesia· clinical usefulness? .... A 392
A. Saaifan, C. Cornet, J. Borgo, N. Belut, M. Labrude, J.P. Berrod, G. Audibert, M.C. Laxenaire

Does systemic verapamil potentiate spinal anaesthesia? ..... A 393
E. Tomatir, S Serin, H Atalay, H. Erbay, L. Kaplan, M Gonullü

A comparison between subarachnoid administration of bupivacaine 0 5%, mepivacaine 2% and prilocaine 5% based on a pharmacodynamic model .... A 394
A Faura, P Gambús, I.F. Trocóniz, E. Izquierdo, L. Parra, D. Pelegrí

A pharmacodynamic model for the effect of subarachnoid injection of bupivacaine 0 5%. prospective validation ..... A 395
P Gambús, I.F. Trocóniz, A Faura, M.J Linares, A Abad, D. Pelegrí

16:15–17:45 Tuesday 28 April 1998 — Room "E"
LOCAL AND REGIONAL ANAESTHESIA (POSTER SESSION)

Unilateral spinal anaesthesia effects of speed of intrathecal injection A.396
A Casati, G Aldegheri, G.L. Cappelleri, A. Leoni, M. Berti, G Fanelli

Continuous spinal anaesthesia with catheter over the needle· preliminary report A.397
M. Wolfs, C. Mardirosoff, L Dumont

Continuous spinal anaesthesia. is there a risk of infection? .... A 398
M. Santamaria, M Möllmann, T. Röttger, U.A. der Landwehr

Respiratory muscle strength after spinal anaesthesia A.399
J. Filby, J.S. Collins, P. Claydon, G H. Mills

A comparative efficacy study of hyperbaric lidocaine 1 5% and mepivacaine 2% for spinal anaesthesia A.400
J.R. Markey, R. Montiague, D.O. Bird, E R. Pedicini, A.P Winnie

Influence of spread of hyperbaric spinal anaesthesia on quality and duration of spinal block A.401
N Kooger Infante, Z Gamulin, E. Van Gessel, A. Forster

Combined spinal/epidural anaesthesia. A prospective clinical comparison between the needle-through-needle and the double-segment techniques A.402
P De Negri, A Casati, A D'Ambrosio, V Tagariello, G Fanelli, F Tarantino

Epidural anaesthesia reduces haemodynamic response to carbon dioxide insufflation during laparoscopic cholecystectomy .... A 403
S C. Alexa, I. Acalovschi

Epidural pneumocephalus after epidural lumbar technique ... A.404
E Mateo, M D López, E. Calabuig, S. Mollner, J. De Andrés, F Grau

10:45–12:15 Tuesday 28 April 1998 — Room "C"
LOCAL AND REGIONAL ANAESTHESIA (ORAL SESSION)

Jet injector compared with needle and syringe for administration of local anaesthetic A.405
R J. Atwater, F.K. Ennekang, B.D. Bertolet

The usefulness of colour Doppler ultrasound guided infraclavicular brachial plexus block ... A.406
S. Honjo

Flow cytometric analysis of *in vitro* effect of bupivacaine on platelet activation .... A 407
S A. Bew, A E Bryant, G.M. Hall

The electroencephalographic effects of spinal anaesthesia A.408
A P. Morley, T G. Short

Thoracic epidural anaesthesia and GUT mucosal perfusion assessed by gastric tonometry and laser Doppler flowmetry in coronary artery surgery A.409
D J Turfrey, M.J. Hodson, N.P. Sutcliffe

Comparison of two anaesthetic procedures for removal of angioplasty introducers A.410
A Rodríguez, O. Campaña, J.C. Díz, J M Rodríguez, J. Cortiñas, P. Otero, J. Alvarez

Subarachnoid block and computerized sedation. haemodynamic profile A.411
M. Sánchez-Castilla, J. López-Martínez, M.S.A. de Lis, P Rodríguez-Tato

14:00–15:30 Tuesday 28 April 1998 — Room "E"
LOCAL AND REGIONAL ANAESTHESIA (ORAL SESSION)

Sedation during regional anaesthesia for orthopaedic surgery propofol *vs* remifentanil … A.412
F. Consiglio, L Serio, E. De Luca, F Golia, P Piccirillo, A Grella

Sedation during spinal anaesthesia· comparison of haemodynamic, anxiolytic and amnesic effects of propofol and midazolam … A 413
A Marşan, S Şen, T. Gumuş, H. Gumüş, N Goğuş, C. Aksu

Haemodynamic effects of general anaesthesia and intravesical bupivacaine for endoscopic bladder surgery … A 414
L Iyılıkçı, D Çatal, E Gökel, M. Guzelsoy, U Onat, C Guler, Z Kırkalı

Urapidil for the treatment of postepidural shivering A preliminary study … A 415
S. Sia

Incidence of hypotension during thoracic epidural anaesthesia combined with general anaesthesia. fentanyl plus etomidate *vs* ketamine plus midazolam … A.416
F. Galindo, C Ezquerro, C Rivera, B López

Pharmacokinetics of epidurally administrated liposomal bupivacaine in humans … A.417
V Umbrain, S. Van Melkebeke, J. D'Haese, F Legros, F Camu

8:30–10:00 Monday 27 April 1998 — Room "C"
PHARMACOLOGY (ORAL SESSION)

Intubating characteristics and duration of clinically effective block after two different doses of cisatracurium … A 418
D. King, P. Bunting, N Huggins, P. Mangat, J Saddler, J. Canning

Duration and recovery profile of cisatracurium after suxamethonium during propofol and isoflurane anaesthesia … A.419
T.J. Gan, I Sanderson, B. Ginsberg, R Alexander, H.E El-Moalem, K Weatherwax, P. Glass

Effects of atracurium in thymectomy for myasthenia gravis … A.420
H.S. Yang, Y. Choi, D.M Lee

Antagonism of neuromuscular block after magnesium sulphate pretreatment … A.421
T. Fuchs-Buder, S Soltez, E. Tassonyi

Spontaneous or neostigmine-induced recovery after three maintenance doses of Org 9487 … A 422
K C. McCourt, R.K. Mirakhur, Carolyn Kerr, H. Sparr

Action duration of atracurium and vecuronium in renal transplantation … A.423
H.S Yang, D.H. Park, D.M. Lee

8:30–10:00 Monday 27 April 1998 — Room "D"
PHARMACOLOGY (ORAL SESSION)

Pharmacokinetic interaction between propofol and alfentanil in healthy male volunteers … A.424
M.J Mertens, J. Vuyk, E. Olofsen, W. Olieman, A.G L Burm, J.G. Bovill

Cerebrospinal fluid concentration of propofol during anaesthesia in man … A 425
M. Abrahams, O. Engdahl, A Bjornsson, M. Vegfors, B Norlander, J. Ahlner, C. Eintrei

Midazolam concentrations in serum and cerebrospinal fluid after epidural administration in dogs … A.426
T. Nishiyama, K Hanaoka

Serum concentrations of the enantiomers of tramadol during patient-controlled analgesia … A 427
S. Grond, T Meuser, H. Uragg, H.J. Stahlberg, K A. Lehmann

Antinociceptive/anti-oedema effects of free and liposomal morphine in a rat model of carrageenan-induced arthritis … A.428
M.M. Puig, O. Pol, S Sánchez, L Rodriguez, M.E. Planas

Experimental *in vitro* release studies of morphine liposomal association … A.429
M Alafandy, C. Robert, V. Maes, F. Legros, F Camu

8:30–10:00 Monday 27 April 1998 — Room "E"
PHARMACOLOGY (ORAL SESSION)

Effects of melatonin by intrathecal injection. An experimental study in the rat … A.430
M. Bahar, M. Chanimov, M.L Cohen, I. Kolfman, Y Grinspoon

Nociceptin inhibits K^+-evoked glutamate release from rat brainstem slices … A.431
B Nicol, D G Lambert, D.J. Rowbotham, D. Smart, A.T. McKnight

Prilocaine and lidocaine inhibit (^{3}H)-noradrenaline uptake into 293-hNET cells … A.432
P I Joyce, R. Atcheson, D.J. Rowbotham, R.D. Blakely, D G. Lambert

Naltrindole-5′-isothiocyanate selectively reverses sufentanil induced respiratory depression in rats … A.433
C. Verborgh, J. D'Haese, T.F Meert

10:45–12:15 Sunday 26 April 1998 — Room "E"
PHARMACOLOGY (POSTER SESSION)

Onset of relaxation after an intubating dose of rocuronium is not accelerated by priming . . . A 434
J C De Mey, D Pattyn, E Mortier, G Rolly

Influence of induction of anaesthesia on intubation conditions after rocuronium-induced neuromuscular block comparison of thiopentone and ketamine . . . A 435
B Hubert, P Hans, J.F Moineau, J F Brichant, F. Damas, P Y. Dewandre, M. Lamy

Rocuronium neuromuscular blockade at the masseter and adductor pollicis muscles in adults . . . A 436
L de Rossi, H Fritz, N -P Preußler, U. Klein

Evaluation of intense rocuronium neuromuscular block using the post-tetanic counts principle . . . A 437
M. Ibsen, P Schultz, D Østergaard, L.T Skovgaard

Antagonism of rocuronium block in the presence of isoflurane . . . A 438
K.C McCourt, R.K Mirakhur, R.N Kumar

Pharmacokinetic and pharmacodynamic model of rocuronium in patients undergoing liver transplantation . . . A 439
J A Alvarez-Gomez, M E. Morales, F Acosta, M.M. Martinez, M.E Estelles, J Fabregat, M A. Rodaguez, T Sansano, P Parrilla, A.J Brugger

Chronic carbamazepine therapy and the duration of neuromuscular blockade by rocuronium . . . A 440
A. Spacek, F.X Neiger, C.-G. Krenn, K. Hörauf, C.K Spiss, H G Kress

Onset, intubating conditions and duration after mivacurium, rocuronium and their combination in young and elderly adults . . . A 441
C Motamed, F Donati

Pharmacodynamics and tryptase release of rocuronium and cis-atracurium in anaesthetised patients . . . A 442
J J. Ariño, J.M Velasco, L Sante, F Lopez Timoneda

Mivacurium neuromuscular effects in elderly *vs* adult patients . . . A.443
R C. Marcos, S. Garcia del Valle, T Delgado, S. Gonzalez, F. Duran

10:45–12:15 Tuesday 28 April 1998 — Room "A"
PHARMACOLOGY (POSTER SESSION)

Assessment of intubating conditions in adults after induction with propofol and varying doses of remifentanil . . . A 444
S Grant, S Noble, A Woods, J Murdoch, J A.H. Davidson

Comparison of three doses of remifentanil for intubation with no muscle relaxation in adults . . . A 445
R Alexander, A. Olufolabi, J.V Booth

Use of remifentanil to prevent a rise in intraocular pressure following suxamethonium and intubation . . . A.446
R. Alexander, R. Hill, W Lipham, H El-Moalem, L Gogineni

Rational alfentanil administration improves haemodynamic stability during direct laryngoscopy under TIVA . . . A 447
M O. Roussat, B. Ouaknine, J.L Bourgain, S Bensaid, G Mamelle, M.F. Cosset, V Billard

Predictive performance of a population pharmacokinetic data set of remifentanil in target-controlled infusion . . . A.448
M J. Mertens, J Vuyk, G Broeders, A G L Burm, J G. Bovill

A prospective, randomized comparison of recovery times after remifentanil/propofol/oxygen, remifentanil/desflurane/oxygen, remifentanil/sevoflurane/oxygen and alfentanil/isoflurane/nitrous oxide anaesthesia for ENT surgery . . . A 449
T Loop, H.-J. Priebe

A prospective, randomized comparison of postoperative patient comfort and satisfaction after remifentanil propofol/oxygen, remifentanil/desflurane/oxygen, remifentanil/sevoflurane/ oxygen and alfentanil/isoflurane/nitrous oxide anaesthesia for ENT surgery . . . A.450
T. Loop, T. Klenzner, H -J. Priebe

Effect of premedicated oral ketamine on reducing the pain both on injection of propofol and on placing the venous catheter . . . A.451
M. Uchiyama, A Yoshino, S. Nagashima, Y Hashimoto, J. Hirashima

Clevidipine and pulmonary extraction during coronary artery bypass graft surgery . . . A 452
A. Vuylsteke, Q.J. Milner, H Ericsson, D Mur, J. Dunning, R D Latimer

Therapeutic dose rates and pharmacokinetics of clevidipine in patients undergoing coronary artery bypass surgery . . . A.453
A. Vuylsteke, Q.J Milner, H. Ericsson, D. Mur, J. Dunning, R.D Latimer

16:15–17:45 Tuesday 28 April 1998 — Room "C"
PHARMACOLOGY (POSTER SESSION)

Low-dose droperidol (0.625 mg, 1.25 mg and 2 5 mg) has no effect on postoperative anxiety, restlessness and overall mood . . . A 454
A M. Morin, T Bezler, L H.J. Eberhart, R. Maier, M. Schreiber, J. Kilian, M. Georgieff

Dimenhydrinate reduces the incidence of postoperative nausea and vomiting in female inpatients . . . A 455
L.H.J. Eberhart, T.I. Bopp, A.M. Morin, M. Georgieff, W. Seeling

Sevoflurane does not reduce postoperative nausea and vomiting compared with enflurane and isoflurane . . . A.456
P. Kranke, C C. Apfel, T. Papenfuss, B Schafers, P Sefrin, N Roewer

Comparative study of the effect of desflurane with nitrous oxide *vs* desflurane without nitrous oxide on postoperative nausea and vomiting in female patients undergoing breast surgery . . . A 457
B F. Vanacker

Ondansetron is more effective than metoclopramide in the treatment of opioid-induced emesis in post-surgical adult patients A.458
F. Chung, R. Lane, C. Spraggs

Comparison of ondansetron and cyclizine in the treatment of early postoperative nausea and vomiting A.459
K. Kyriakides, S Hussain, J. Harrison, A. Webb, G. J Hobbs

Systemic *vs* single ondansetron administration in preventing nausea and vomiting as well as pruritus after intrathecal morphine administration A.460
V. Dimitriou, G.S. Voyagis, G Tsiganos, A. Douma, A. Malefaki, C Pratsas

Influence of intrathecal combination of clonidine with morphine on nausea and vomiting as well as pruritus A.461
G.S. Voyagis, V. Dimitriou, A. Douma, E. Miniati, E. Koukou, G. Tsiganos

Clonidine premedication in middle ear microsurgery .... A 462
J. Marchal, M. Poncela, J. Rosell, A. Gómez, J Cervantes, M.C. Martínez, A. Delgado

Effect of clonidine premedication on the induction dose of propofol and haemodynamic parameters A.463
M. Subrahmanyam, M. Rea, R. Cooper

16:15–17:45 Tuesday 28 April 1998 — Room "D"
PHARMACOLOGY (POSTER SESSION)

Emergence and recovery from desflurane or isoflurane prolonged anaesthesia for acoustic neuroma surgical procedures A.464
D. Boisson-Bertrand, M.C. Laxenaire, G. Lapeyre

Effects of nitrous oxide as second gas during desflurane anaesthesia .... A 465
P. Garrido, M.V. Caldera, E. Deudero, M.J Villagrán, B. Martinez, A. Criado

Recovery profile of desflurane, propofol and isoflurane anaesthesia in morbidly obese patients preliminary results .... A 466
P. Vila, J. Canet, C. Bertrán, E. Massó, E. Mata, F. Vidal

Isoflurane enantiomers in humans A.467
H.A Häberle, H G. Wahl, H.J. Jakubetz, V. Schurig, H. Krause, R. Schmidt, K. Unertl, H J. Dieterich

Reduction of minimum alveolar concentration of isoflurane by tramadol in comparison with morphine in rats A.468
M.H. de Wolff, P.F. Wouters

The analgesic potency of xenon and nitrous oxide in humans evaluated by experimental pain A.469
S. Petersen-Felix, M. Luginbühl, T. Schnider, M. Curatolo, L. Arendt-Nielsen, A M. Zbinden

Effective concentration$_{50}$ for propofol with 70% xenon *vs* 70% nitrous oxide A.470
S Schraag, M.N Schreiber, J. Flaschar, T Marx, G.N C. Kenny, M. Georgieff

Quantification of the electroencephalographic effects of propofol using semilinear canonical correlation A.471
P. Gambús, I.F. Trocóniz, T.W. Schnider, C.F. Minto, S.L Shafer

Assessment of drug-drug interactions in patients receiving postoperative analgesia by intravenous PCA A.472
A. Montes, M.M. Puig

8:30–10:00 Sunday 26 April 1998 — Room "E"
PAEDIATRIC ANAESTHESIA AND INTENSIVE CARE (ORAL SESSION)

Which method of induction with sevoflurane in children. Incremental or high concentration, with or without nitrous oxide? A.473
M.C. Dubois, V. Piat, O. Lamblin, I. Murat

Quality of recovery in children· sevoflurane *vs* propofol .... A 474
V. Picard, L. Dumont, M. Pellegrini, A. Bruce, E. Tassonyi

May sevoflurane be preferred to halothane in paediatric ophthalmological anaesthesia? A.475
E. Tomatir, C. Yildirim, S. Serin, H. Atalay, H. Erbay, M. Gönullü

Neuromuscular effects of mivacurium in children Effect of sevoflurane A.476
A. Martínez-Tellería, M.E. Cano, M.M Rodríguez

Endotracheal intubating conditions after cisatracurium in infants and children .... A 477
I. Waite, G Meakin, O.A. Meretoja, R. Perkins, T. Taivainen, K Wirtavuori, A K Murphy, L. Raiha

An audit of simple dental extractions in children. Chair dental anaesthesia or the laryngeal mask? .... A 478
A.E. Slaymaker, A.C. Quinn, R.S.E. Edmondson, E.M McAteer

8:30–10:00 Monday 27 April 1998 — Room "A"
PAEDIATRIC ANAESTHESIA AND INTENSIVE CARE (ORAL SESSION)

Suitability of behavioural items for the assessment of postoperative pain in infants A.479
W. Büttner, W. Finke, M. Hilleke, A Munker

Comparison of two paediatric pain scores in urological surgery A.480
J.C Ortiz, J. Mayoral, S Sabaté, P Baxarias

Clonidine prolongs bupivacaine spinal anaesthesia in newborns A.481
A. Rochette, O. Raux, J. Borry, C. Vergnes, F d'Athis

Effects of spinal anaesthesia with pethidine as sole agent, on plasma cortisol and glucose concentrations after lower abdominal surgery in children A.482
C. Mitre, I Acalovschi

Long-term epidural anaesthesia with ropivacaine in a small child ..... A 483
B. Gustorff, P. Lierz, K. Hoerauf, K. Dieckmann, T.H. Knocke, H.G. Kress

Technical aspects of paediatric epidural catheter insertion: a prospective study of 338 cases ... A.484
F Roelants, H. Waterloos, L J. Van Obbergh, F. Singelyn, J.M. Gouverneur, F. Veyckemans

8:30–10:00 Tuesday 28 April 1998 — Room "E"
PAEDIATRIC ANAESTHESIA AND INTENSIVE CARE (ORAL SESSION)

How reliable are oscillometric blood pressure monitors in neonates and infants? A.485
B Oldorp, S. Mieke, G. Papadopoulos

An alternative method to determine the size of laryngeal mask airway in children ..... A 486
L. Gallart, A Mases, J.A. Martinez-Pérez, A. Montes, S Fernández-Galinski, M M Puig

Sedation for paediatric endoscopic procedures. comparison of two techniques A.487
C E Lesmes, H. Hager, E Nussenson, Y. Katz

Is cooling essential in paediatric cardiac surgery? Clinical outcome after high-flow normothermic cardiopulmonary bypass A.488
A B. Lal, A F. Corno, A. Valori, D.N. Robinson

Low dose oral ketamine augments midazolam premedication in paediatric patients A.489
W. Funk, T Riedl, J. Schickendantz, K. Taeger

Efficacy and tolerability of tropisetron in the prevention of nausea and vomiting in children undergoing tonsillectomy and/or adenoidectomy A 490
C. Dillier, M. Weiss, A. Ch Gerber

14:00–15:30 Tuesday 28 April 1998 — Room "A"
PAEDIATRIC ANAESTHESIA AND INTENSIVE CARE (ORAL SESSION)

Intrathecal morphine for pain control in adolescents after scoliosis surgery ..... A 491
M.J. Colomina, C. Godet, A Vivó, J. Bagó, F Pellisé, C. Villanueva

Biblocks in congenital club foot surgery ..... A 492
E. Civran, M. Grazzini, D. Carreri, G Manani, G P Giron

Infraclavicular block in children: is it an alternative to axillary block? ..... A 493
R J. Steur

Caudal ropivacaine (0.25%) and bupivacaine for postoperative pain relief in children A.494
D. Ozcengiz, H Özbek, H. Ünlügenç, G Işık

Comparison of postoperative analgesia in children after continuous i v infusion of morphine or nalbuphine through a single-use infuser (Baxter) ..... A 495
D. Velegrakis, C. Loizou M. Papageorgiou, A. Malissiova, A Avgerinopoulou

16:15–17:45 Tuesday 28 April 1998 — Room "A"
PAEDIATRIC ANAESTHESIA AND INTENSIVE CARE (POSTER SESSION)

Does propofol protect against postoperative vomiting after tonsillectomy in children? ..... A 496
A. Malissiova, E. Kalliardou, S. Mitsiou, P Matsota, M. Papageorgiou

Incidence and therapy of midazolam-induced hiccups in paediatric anaesthesia A.497
P Marhofer, C. Glaser, C.G Krenn, C. Grabner, M. Semsroth

Reinforced laryngeal mask airway for adenotonsillectomy in children: problems and comparison with tracheal intubation ..... A 498
F Cassinello, L Ruiz, L Muñoz, J. Rodrigo, A Mayor, J.C. De la Pinta

End-tidal and transcutaneous carbon dioxide monitoring during paediatric laparoscopic surgery ..... A 499
M. Dubreuil, F Malgrot, B. Grenier, Y Meymat, F. Masson, L Sanz, A Dupeyrat

A paediatric sedation unit in a university hospital: a one-year survey A.500
D. Gozal, A Kadari, Y. Gozal

Physical and emotional conditions after ambulatory paediatric surgery: results of 413 questionnaires as part of postoperative quality assurance A.501
M. Kumm

Adverse effects after paediatric magnetic resonance imaging A.502
A. Sandner-Kiesling, M. Vizenci, A Fall, G. Schwarz, F. Ebner, W.F List

Tonsillectomy for children: evaluation for ambulatory practice A.503
S. Colombani, C Boudey, D. Esteben, M. Milacic, A.M. Cros

Evaluation of sevoflurane anaesthesia for children requiring cardiac catheterization ..... A 504
C Giannelloni, F Abdo, C. Dauphin, I. Curt, M Montetagaud, J.E Bazin

Spontaneous recovery of neuromuscular transmission after mivacurium in children under balanced, halothane and isoflurane anaesthesia A.505
B. Woloszczuk-Gebicka

8:30–10:00 Tuesday 28 April 1998 — Room "B"
OBSTETRIC ANAESTHESIA (ORAL SESSION)

Determination of the minimum local analgesic concentration of epidural ropivacaine in labour A.506
G. Capogna, D. Celleno, G. Lyons, M. Columb

A comparison of ropivacaine 0.10% and sufentanil 10 μg with ropivacaine 0.20% for epidural labour analgesia A.507
D. Celleno, G. Capogna, D. Quarta, A. Amato, M. Emanuelli

Ropivacaine 0.10% plus sufentanil and bupivacaine 0.0625% plus sufentanil are equianalgesic mixtures for epidural analgesia during first stage of labour A.508
G. Capogna, D. Celleno, D. Quarta, A. Amato

Epidural analgesia, progress of labour and maternal motor blockade. A comparison of ropivacaine and bupivacaine A.509
G. Gobber, T. Battistini, G. Apollonia, N. Facchin, R. Cassol, M.C. Luise, A. Mazzaro, A. Tanfani, F. Laterra, L. Chiarini

Ropivacaine 2 mg/ml *vs* ropivacaine 1 mg/ml + sufentanil 0.2 μg/ml for extradural analgesia in labour A.510
S. Lopez, J.M. Ferrer, G. Aya, R. Mangin, C. Robert, J.J. Eledjam

Minimum local analgesic volume for epidural bupivacaine 0.125% in labour A.511
G. Lyons, M.O. Columb, H. Gorton

14:00–15:30 Tuesday 28 April 1998 — Room "B"
OBSTETRIC ANAESTHESIA (ORAL SESSION)

Patient-controlled analgesia: extradural fentanyl and intravenous morphine compared after Caesarean section A.512
U. Saleh, D. Cooper, D. Ryall, K. Kokri, W. Desira, M. Tremlett

Effect of fluid preload on coagulation as measured by thromboelastography A.513
H. Gorton, G. Lyons, P. Manraj

Effects of the Valsalva manoeuvre on the cerebral circulation in pregnancy A.514
R. Buckland, D. Radakrishna, J. Pickett, B. Matta

Vascular effects of propofol and thiopentone in the isolated perfused human placental cotyledon A.515
R.H. Jensen, O.B. Petersen, J.H. Christensen, A. Formann

Incidence of fetal acidaemia after spinal anaesthesia for elective Caesarean section – a persistent trend in the midnineties? A.516
G. Schuepfer, C. Konrad, M.D. Mueller, S. Durrer, H. Brühwiler

Influence of urodilatin on perfusion pressure in pre-eclampsia. A study of the placental model *in vitro* A.517
D. Szukiewicz, A. Szukiewicz, D. Maślińska, M. Olszewski

16:15–17:45 Monday 27 April 1998 — Room "F"
OBSTETRIC ANAESTHESIA (POSTER SESSION)

Intrapartum fetal oxygen saturation monitoring during epidural analgesia for labour A.518
P. Fusco, P. Forleo, G. Capogna, D. Celleno

A large randomized controlled trial comparing epidural bupivacaine with intramuscular pethidine for pain relief in labour in primiparous women A.519
B.A. Loughnan, F. Carli, M. Romney, C. Dore, H. Gordon

Effect of the addition of a mini dose of clonidine to intrathecal sufentanil for labour analgesia A.520
L. Saltel, C. Cabiro, M. Cesarini, M. Mekki, J. Lichay, R. Torrielli

Parturient-controlled epidural analgesia: the advantages of programming volume limit per hour A.521
D. Bresard, F. Nemoz, D. Goumard, J. Fusciardi

Intrathecal bupivacaine reduces uterine activity in labouring and non gravid rats A.522
P. Malassiné, G. Germain, J. Seebacher, J. Rousseau, P. Coriat

Current management of inadvertent dural taps occurring during epidural analgesia for pain relief in labour: a French postal survey A.523
V. Souron, L. Simon, P. Sacquin, J. Hamza

Obstetric analgesia as a guide to progress of labour. Is it possible? A.524
N. Sáiz-Sapena, A. Macías, A. Sáez-Fernández, R. Zarauza, R. Calderón, M. Adame

Combined spinal-epidural analgesia in labour: comparison of two doses of intrathecal bupivacaine with fentanyl A.525
B.B. Lee, W.D. Ngan Kee

Thermoregulatory response during labour, with and without epidural analgesia A.526
O.P.F. Panzer, N. Ghazanfari, M. Greher, A. Donner, P. Germann, Y. Yücel, D.I. Sessler, A. Kurz

10:45–12:15 Sunday 26 April 1998 — Room "F"
INTENSIVE CARE MEDICINE (POSTER SESSION)

Effect of endothelin-1 on LPS clearance and bacterial killing in rabbits A.527
T. Koch, S. Heller, A. Heller, T.-L.-H. Phan, J. Schmeck, R. Urbaschek

Effects on platelet function of systemic inhibition of endogenous nitric oxide production by L-NMMA A.528
J. Albert, H. Wallén, N. Li, C. Frostell, P. Hjemdahl

LPS does not induce changes in hepatocellular microtubule cytoskeleton and phosphorylation of MAP-kinases A 529
S Russwurm, M. Wiederhold, K J Böhm, P. Muhlig, I Stonans, E. Unger, K Reinhart

Human peripheral blood mononuclear cells express mRNA for procalcitonin A 530
M Oberhoffer, S Russwurm, I Stonans, E Stonane, U. Junker, H Vogelsang, L Jager, K Reinhart

Effects of L-NAME on PMN-function and bacterial clearance in rabbits A.531
S Heller, J. Weikel, A. Heller, J Schmeck, R Urbaschek, T Koch

Distribution of microcirculatory blood flow in the gastrointestinal tract during haemorrhagic shock A 532
V. Krejci, D. Erni, A. Banic, A. Wheatley, G H. Sigurdsson

Tissue hypoxanthine reflects splanchnic vulnerability in porcine endotoxin shock A 533
A Oldner, M. Wanecek, M Goiny, A Rudehill, U Ungerstedt, A. Sollevi

Mitochondrial redox state in septic shock A 534
K. Yassen, H.F Galley, A. Lee, N.R Webster

Role of the liver in interleukin-10 production in a porcine model of endotoxicosis A 535
B Ickx, C.E. Velghe-Lenelle, S. Pierre, J Closset, V Donckier, M Goldman, A d'Hollander

14:00–15:30 Monday 27 April 1998 — Room "F"
INTENSIVE CARE MEDICINE (ORAL SESSION)

Prognostic value of immunomonitoring in patients with polytrauma and sepsis A 536
K. Tschaikowsky, N Lehnert, A Schiele, M Hedwig-Geissing, S. Kirchner-Holley, K Spegel

Lactic acidosis during fulminant hepatic failure determinants and infectious complications A 537
J Martínez, G. Martínez-Pallí, J. Beltran, J. Ortells, P. Taurà, C. Gomar

Influence of n-acetylcysteine on leucocyte functions in critically ill patients A 538
G. Groth, A. Heller, R Breitkreutz, M. Quintel, T. Koch

Plasma purification in treatment of patients with destructive forms of pancreatitis A.539
V.V Mamontov, V.A Mokhov, V.N Lucach, S I Vozlublenyi

Procalcitonin and systemic inflammatory response syndrome in postoperative intensive care patients A 540
G. Molter, R Kottke, S Walcher, S. Soltèsz, K Hegenauer, M. Silomon

Criteria of severity and prognosis of severe asthma and status asthmaticus a new approach to diagnosis A 541
VP Shano, A.N. Nesterenko

Severe asthma and status asthmaticus. a role of xenosplenoperfusion in intensive care based on SIRS conception A.542
V.P. Shano, A.N Nesterenko

8:30–10:00 Tuesday 28 April 1998 — Room "C"
INTENSIVE CARE MEDICINE (ORAL SESSION)

Tip-Hub story. Our experience A 543
G Gucev, A. Damevski, V. Teneva, J. Hristova, M Micevski, M Petrovska, Z. Cekovska, T Grdanoska, L. Damevska

Incidence of infection of arterial catheters in intensive care patients A.544
P. Kalfon, J Prost, D Kenmogné, F.H Ansari, K. Chebbo, M Niault, F. Thomas, D. Francoual

An intravenous catheter does not influence cytokine plasma concentrations A.545
H Keyer, K. Vissers, C. De Deyne, G. Vundelinckx, R Heylen, R De Jongh

Central venous catheterization in leukaemic patients with bleeding risk A 546
A.A. Cogliati, G. Conti, L Tritapepe, B. Bottari, G. Rosa

Significance of *Candida* species growth in respiratory samples from non-neutropenic patients in a surgical ICU A.547
A Alcón, N. Fábregas, F.X. González, M A. López-Boado, J P de la Bellacasa, J. Balust, E. Zavala

Community acquired pneumonia of rare origin A.548
I Varga, B. Hauser, C. Diószeghy, E Benkovics, I Pénzes

14:00–15:30 Tuesday 28 April 1998 — Room "F"
INTENSIVE CARE MEDICINE (ORAL SESSION)

Early postoperative percutaneous dilatational tracheotomy after cardiac surgery A.549
M. Böckelmann, N. Hübner, W. Rees, U Christmann, H. Warnecke

Early extubation after cardiac surgery. safe postoperative care management A 550

However, no responsibility is assumed by the organisers for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions or ideas contained in the material herein. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosages should be made.

EPIDEMIOLOGY IN ANAESTHESIA AND INTENSIVE CARE

A.1 Abdominal aortic surgery: cardiac enlargement on preoperative chest x-ray as an independent predictor of postoperative left ventricular failure

A. Declerck, J Karayan, K Dhoste, D Thomas, J Fusciardi *Department of Anaesthesiology, University Hospital of Poitiers, 86021 Poitiers, France*

Introduction: Lowered LVEF is a predictor of post operative LVF during AAS (1) Although a radiologic cardio-thoracic ratio (CTR) > 0 5 indicates LVEF < 40% in as much as 70% of coronary artery-diseaded (CAD) patients only Foster et al (2) demonstrated an association between preoperative CTR and post operative LVF The aim of our study was to evaluate several preoperative classical predictors and variables, including CTR, in prediction of LVF after AAS

Materials and Methods: During a 52 months period, 223 consecutive patients undergoing planed AAS were prospectively studied. In every case we noted age, previous myocardial infarction (MI), previous episod of acute LVF, CTR > 0 5 or not, regional hypokinesia on TTE, gated nucleide LVEF < 50% or not In case of persistent LVF surgery was delayed Both anaesthesia, per and post operative monitoring with Swan-ganz catheter and ST segment monitoring, agressive treatment of hemodynamic abnormalities and ischemia, post operative ventilation and analgesia, were standardized LVF was defined by clinical and radiologic signs of pulmonary edema and either PAOP > 18 mmHg or sucessful response to diuretics and/or inotropic support Results were analyzed by univariate and multivariate analysis.

Results: Aortic clamping level was mainly infrarenal (93%) Post operative LVF occurred in 20 patients (8 8%) without any related death. Main results are given in the Table.

Preoperative variable	n with outcome and variable/n with variable	Univariate Analysis p value	Multivariate p value/OR
Age >65 yr	16/112	0 01	NS
Previous MI	4/29	NS	NS
Previous LVF	5/11	0 00001	0 0023/10 735
Goldman' score 3–4	10/54	0 0012	NS
Detsky' score 2 + 3	2/4	0 0003	NS
CTR > 0 5	11/51	0 0002	0 0197/3.718
Hypokinesia	8/45	NS	NS
LVEF < 50%	5/47	0 02	NS

Discussion, Conclusion: Our main adjunct is to show that, surprisingly, a simple and cheap preoperative sign, i.e CTR > 0 5, is one of the most powerful independant predictor of post operative LVF.

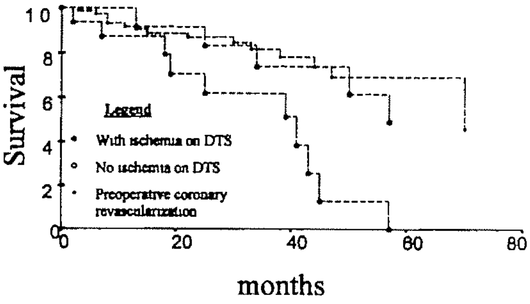
A.2 Preoperative thallium imaging and coronary revascularization in critical limb ischaemia: impact on perioperative morbidity and long-term survival

G Landesberg, Y. Wolf, M Mossen, D Schechter, M Bocher, H Anner, Y. Berlatzky *Departments of Anesthesiology, Vascular Surgery, Cardiology and Nuclear Medicine, Hadassah University Hospital, Jerusalem, Israel*

Background: The value of dipyridamole-thallium scanning (DTS) in predicting perioperative morbidity has been studied. Data on the effect of DTS and selective preoperative coronary revascularization (Cor-Rev) on long-term outcome, however, is lacking

Methods: 113 patients with critical lower limb ischemia scheduled for distal arterial bypass surgery underwent routine preoperative DTS. Patients with moderate-severe revesible defects on DTS had coronary catheterization and PTCA or CABG if indicated Their perioperative and long term morbidity and mortality were recorded

Results: 54 (47 8%) patients had history of heart disease, DTS was abnormal in 60 (53.1%), showing reversible ischemia in 49 (43.4%). Of 33 (29.2%) patients referred to coronary catheterization, 9 underwent PTCA and 4 had CABG without complications Surgery was performed in all but 2 patients; 2 (1.8%) died postoperatively, 3 (2 7%) sustained nonfatal postoperative MI and 2 had unstable angina None of the 13 patients with preoperative Cor-Rev had perioperative cardiac complication No clinical or DTS variable correlated with perioperative events. During follow-up (33.4 ± 2.2 months) 30 (28 0%) patients died Survival was lower with moderate-severe ischemia on DTS (40 ± 4 vs. 63 ± 4 months; $p < 0\,005$). Patients with preoperative Cor-Rev followed a survival curve similar to those without ischemia on DTS (61 ± 8 vs. 63 ± 4 months; NS) and significantly different from those with such defect without Cor-Rev (34 ± 5 months; $p < 0.017$)



Conclusion: In patients with critical limb ischemia, routine screening with DTS and selective preoperative coronary revascularization result in low perioperative cardiac morbidity and mortality and longer survival

A.3 Electrocardiographic and cardiokymography stress testing for cardiac risk assessment in patients undergoing non-cardiac surgery

A Gauss, H.J Roehm, A Schaeuffelen, T. Vogel, U Mohl, M Georgieff, W. Schuetz. *Department of Anesthesiology, University of Ulm, D-89075 Ulm, Germany*

Background and Goal of Study: Preoperative risk stratification of patients with coronary artery disease (CAD) undergoing noncardiac surgery remains challenging (1). The value of preoperative stress cardiokymography (CKG) in predicting perioperative cardiac complications is still uncertain The goal of this study was to assess the predictive value of clinical variables, stress ECG and CKG

Materials and Methods: After obtaining institutional approval and informed consent 171 patients with definite CAD or at high risk for it scheduled for major elective noncardiac surgery were prospectively enrolled. All patients underwent preoperative bicycle ergometer testing with simultaneous measurements of ECG and CKG A 12-lead ECG and CK-MB- and Troponin-T-levels were obtained daily during the first five postoperative days. ECG and CKG analyses were performed by blinded investigators. A peri-operative cardiac complication was defined as myocardial infarction, prolonged myocardial ischaemia (Troponin T > 0 1 ng/ml or ST-depression ≥0 1 mV on at least two successive days), congestive heart failure or ventricular tachyarrhythmias. Potential univariate correlates of adverse outcomes were identified by Fisher's exact test.

Results and Discussion: 13 patients (7 6%) developed major perioperative cardiac complications myocardial infarction occurred in three and prolonged myocardial ischaemia in 10 patients. Definite CAD and exercise ECG were significant predictors of cardiac events (Tab) Although previous studies investigating CKG for diagnosis of CAD showed higher predictive accuracy for CKG compared to ECG (2), in our trial CKG was not predictive of perioperative cardiac complications However, combining clinical variables as definite CAD or specific types of surgery with positive ECG- and CKG-results increased the prediction of cardiac events to 34%, if three of these variables were present

Table Sensitivity (Sens), Specificity (Spec)

	Sens	Spec	Predictive value	p
CAD	92%	57%	15%	0 001
ECG	69%	73%	18%	0 03
CKG	77%	47%	11%	0 15

Conclusions: Stress ECG and definite CAD in contrast to CKG predicted cardiac events Combining clinical data with cardiac testing improved preoperative risk assessment and could limit needless investigations.

A.4 Preoperative coronary angiography in patients undergoing abdominal aortic surgery: five years' experience

D. Eyraud, M. Bertrand, M H Fléron, B. Riou, P Conat *Departement of Anesthesiology, Pitié-Salpêtriere, Paris, France*

Aim of the Study: to determine preoperative clinical parameters associated with the indication for preoperative coronary angiography (CA) in patients scheduled for abdominal aortic surgery (AAS) in the 1993–1997 period

Methods: 666 consecutive patients underwent CA based on the following indications angina pectoris or history of myocardial infarction (MI), age between 60 and 71 years and aneurysm procedure or age <71 and combined surgery (aorta and carotid, renal or mesenteric artery).

We retrospectively considered the decision to proceed or not to CA as justified when: 1) CA was performed and followed by coronary revascularization without cardiac complication after AAS. 2) CA was not performed and no cardiac complication (death, MI, heart failure) occurred after AAS.

We retrospectively rejected the decision when: 1) CA was not followed by revascularisation or the following revascularization was associated with cardiac complication. 2) CA was not performed and cardiac complication occurred after AAS. Odds ratio (OR) and their 95% confidence intervals (CI) were calculated.

Results: CA was performed in 302 patients. In 54 (18%) CA was followed by revascularization. Twelve patients (3%) presented severe cardiac complication (8 death) after AAS over the 364 patients without preoperative CA,. Using a multivariate analysis, age, type of aortic surgery (aneurysm versus occlusive aortic disease), combined surgery, serum creatinine >150 μmol/l hypertension, history of heart failure or atrial arrhythmia were not associated with justified CA. Preoperative predictive factors for justified CA are summarized in the table:

	OR [IC 95%]	P
Angina pectoris	3.22 [2.43–4.26]	0.0001
History of MI	2.8 [2.05–3.9]	0.001
History of revascularization	0.3 [0.18–0.5]	0.02
Diabetes	2.16 [1.46–3.19]	0.04
β-blockers	2.14 [1.76–2.86]	0.01

Conclusion: Preoperative CA should be performed in patients with clinical evidence of coronary artery disease or potential silent coronary artery disease (diabetes, β-blockers). Conversely, CA might not be performed in other cases especially in revascularized patients without recurrent angina pectoris

A.5 Hypertension and perioperative cardiovascular complications: meta-analysis of observational studies

S.J. Howell, J.W. Sear, P. Foëx. *Nuffield Department of Anaesthetics, Radcliffe Infirmary, Oxford, UK*

Background and Goal: Hypertension is often dismissed as a risk factor for preoperative cardiovascular complications because it does not appear in risk equations such as those of Goldman et al., and Larsen et al. (1, 2) We undertook a meta-analysis of observational studies of risk factors for perioperative cardiovascular complications to elucidate the role of hypertensive disease in this context.

Materials and Methods: Studies were identified by a search of the Medline database and by searching the reference lists of papers obtained from Medline and of relevant review papers. Studies were sought which gave information on the possible association between hypertensive disease and perioperative complications. The aim of this meta-analysis was to examine the effects of hypertensive disease and studies which defined hypertension solely in terms of an elevated admission blood pressure were excluded. Studies were included if the crude data on hypertension and the occurrence of complications could be extracted from the publication. For each study the crude odds ratio for the effect of hypertension and its variance were calculated. Fixed effects meta-analyses was performed using standard methods. (3) A statistical test for heterogeneity was also performed.

Results: Fourteen studies ranging in size from 60 to 2,609 patients were identified for inclusion in this meta-analysis. A total of 9,223 patients was included.

Using fixed effects meta-analysis, the pooled log odds ratio for the effect of hypertension was 0.44, giving the odds ratio of 1.55 (95% CI 1.29 to 1.87, $z = 4.63$, $p < 0.001$). The test for heterogeneity was not significant ($Q = 14.84$, $p = 0.32$ 13 df).

Conclusion: This meta-analysis demonstrates a significant association between hypertensive disease and perioperative cardiovascular complications.

A.6 Laparoscopy *vs* laparotomy for cholecystectomy in elderly patients

M. Zając, K. Zając, Zb. Engel. *Department of Anestesiology and Intensive Care, Jagiellonian University, Kraków, Poland*

Background and Goal of Study: This study shows a particular usefulness of laparoscopic cholecystectomy in patients aged 70 or over in comparison with the standard laparotomy.

Materials and Methods: 110 patients ASA 2 and 3 scheduled for cholecystectomy were blindly randomized into 2 groups: laparotomy (n = 52) and laparoscopy (n = 58). All patients were premedicated orally with midazolam 7.5 mg and ondansetron 4 mg. Anaesthesia was indused with fentanyl, methoheksital, suxamethonium and after intubation maintained with 66% nitrous oxide in oxygen, and atracurium; on pain stimuli fentanyl was added. IPPV ventilation supplied patients with 10 ml/kg of tidal volume. The following data were analyzed: ASA, postoperative side-effects and complications, duration of surgery and length of stay in hospital. All the results are expressed as mean ± SD and a statistical analysis ($p < 0.05$ significant) was done using chi-square test.

Results: Age, weight, height and gender were similar between the groups.

	Laparoscopy	Laparotomy
Number of patients	58	52
Age (yrs) (ns)	76.7 ± 2.2	75.9 ± 2.1
ASA 3 ($p < 0.05$)	39 = 67.4%	24 = 46.1%
Time of operations (ns)	54′ ± 5′	47′ ± 4′
Days of stay in hospital ($p < 0.05$)	<1	9.1 ± 2.8
Required analgesics	tramadol 1 dose	opioides every 4–5 hrs
Complications	no (incl. 7 days observation)	yes

In the laparotomy group severe complications were observed (respiratory insufficiency 9 = 17.3%, myocardial infarction 4 = 7.7%, transient CNS episodes 1 = 1.9%) although haemo-dynamic parameters and haemoglobin saturation did not show any evidence of instability during anaesthesia.

Conclusions: Laparoscopy can be strongly recommended for cholecystectomy in the elderly since it reduces incidence of postoperative side-effects (is less painful) as well a severe complications and ensures less traumatic recovery.

A.7 Evaluation of Possum as a tool for quality assurance in an anaesthesiological ICU

K. Schulze, R. Uebelen, Lj. Verner, A. Bornscheuer, H. Hecker[1], S. Piepenbrock. *Department of Anaesthesiology, [1]Department of Biometry Medical School Hannover, Germany*

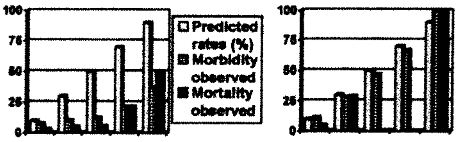
Background and Goal of Study: POSSUM is a Physiological and Operative Severity Score for the enUmeration of Mortality and morbidity. Aim of our study was to assess the predictive accuracy for morbidity and mortality as important outcome determinants in surgical patients.

Material and Methods: 207 patients were scored prospectively in our ICU after surgical procedures of 3 different clinics: Abdominal surgery, Urology and Traumatology. Evolving complications during intensive care treatment were documented as well as the length of stay in ICU and outcome. The predictive accuracy of POSSUM was assessed for each surgical department by the calculation of receiver operating characteristic (ROC) curves with determination of their area under curve (AUC). The mortality and morbidity predictor equations published by Copeland et al. [1] were applied to compare predicted deaths and complication rates with reported deaths and complication rates. A "Hannover" predictor equation was calculated on our data by logistic regression.

Results and Discussion: 41 patients developed complications (19.8%) and 12 died during their course in ICU (5.8%). Table 1 shows the calculated AUC data for each surgical department regarding morbidity and mortality:

Clinic	n	AUC morbidity	AUC mortality
Abd. Surgery	92	0.680	0.893
Urology	95	0.767	0.740
Traumatology	20	0.797	0.833
All patients	207	0.720	0.782

The Copeland predictor equations resulted in a lack of fit by overestimating the number of complications and deaths. They were adjusted by the "Hannover" predictor equations (Fig. 1):



These data show that prediction of morbidity and mortality is possible within a reasonable range.

Conclusion: POSSUM is applicable to patients from different surgical specialties and therefore appropriate for an anaesthesiological ICU. Risk adjustment has to be done, thereby managing to perform sequential analysis of morbidity and mortality rates as important factors for quality control.

A.8 Development of a high dependency unit illness severity scoring system

K Stuart-Smith, C Spring, E. Whitley, A. McCrirrick *Gloucester Royal Hospital, UK*

Introduction and Goal of Study: High dependency units (HDU's) have been developed to provide a level of care intermediate between the intensive care unit (ICU) and the general ward. Illness severity scoring systems such as APACHE II were developed for critically ill ICU patients (1). They require data from invasive monitoring, are complex and may be invalid for predominantly surgical HDU patients (2). This study outlines the development of a simple HDU scoring system

Method: Data, including chronic health status, were obtained from 220 surgical HDU patients. Pulse rate and non-invasive arterial pressure were combined into a simple table to give a two point cardiovascular assessment FiO2 and SpO2 were similarly combined to give three grades of respiratory status. Renal function was assessed from urine output. Data were analysed initially by univariable logistic regression against either survival or death within 14 days/transfer to ICU Variables found to be significant at the 5% level were include in a multivariable analysis to identify those factors independently related to outcome.

Results: The five acute variables below were shown to significantly affect outcome.

Variable	P value	Projected weighting
Albumin	p < 0 01	0–3
SpO2	p < 0.03	0–5
Renal	p < 0 01	0–6
Age >75 yrs	p < 0.07	0–2
CNS	p < 0.07	0–5

The relative impact on outcome and hence the projected weightings for the scoring system were obtained from the coefficient multivariable model Primary surgical diagnosis, chronic health status, cardiovascular status, temperature, Hb or WBC were not found to independently affect outcome.

Conclusion: We have developed a simple five point illness score for HDU patients requiring only basic physiological data. Further validation is in progress.

A.9 Early prognosis value of SAPS II score after orthotopic liver transplantation

P. Revel, R. Valles, E. Arthot, F. Semjen *Department of Anaesthesia, Pr Erny, Hôpital Pellegrin Bordeaux, France*

Orthotopic Liver transplantation (OLT) is an heavy medico-surgical procedure regularly threatening the vital prognosis of receivers

To dispose of an objective vital score, we try to determine the accuracy of SAPS II (Simplified Acute Physiology Score), as an initial indicator of liver transplantation mortality.

Patients and Methods: 75 patients representing 82 OLT (50 male, 25 female) have been prospectively studied during a two year period SAPS II score was determined every day during three days after OLT: (SAPS 1, 2, 3).

In order to have a single value during the whole postoperative period, the sum of SAPS 1, 2, and 3 was calculated. (Σ).

Statistical analysis was performed with ANOVA. Results are expressed in mean ± sd, and $p < 0.05$ was considered significant.

Results: Global mortality during the study period was 18.5% (15 patients).

The difference between dead or alive patients with their SAPS scores are represented in Table 1

Table 1

	SAPS 1	SAPS 2	SAPS 3	Σ
Alive	24 ± 10	20 8 ± 11	19 2 ± 11	64 7 ± 30
Dead	38 6 ± 11	38 9 ± 14	37.1 ± 15	115 4 ± 39
p value	0 00007	0 00001	0.00001	0 0000001

Table 2 shows percent of survivor for each corresponding group of sum (Σ) value ($p = 0.000004$)

Table 2

Σ	<40	40–80	80–120	120–160	>160
% Survivor	100	90	70	30	0

Conclusions: SAPS II scores can be considered as good indicators of vital prognosis after OLT. Patients mortality shows significant variations according to the sum (Σ) value. These scores allow simple, quick and powerful determination of death risk in the early period after OLT.

A.10 Using revised simplified acute physiology score (SAPS II) in patients admitted to a neurosurgical intensive care unit

D. Siao, G. Boulard, B Grenier, R. Mesli, P Maurette *Department of Anesthesia 3, Pellegrin Hospital, Bordeaux, France*

Background and Goal of Study: Prospectively acquired data from patients admitted in the neuro-surgical intensive care unit (NICU) were studied for evaluating the predictive accuracy of the revised Simplified Acute Physiology Score[1] (SAPS II) for outcome quality under the framework of quality assurance. SAPS II employs twelve physiological variables with additional weights for age, type of admission and three underlying diseases (AIDS, metastatic malignancies or hematological malignancy)

Materials and Methods: A six months survey for all patients staying more than 24 hours in the NICU and excluding all patients under sixteen years old Data on chosen demographic characteristics and specific physiological variables for SAPS II were collected within the 24 first hours of admission. Discharge vital status (dead or alive) and the length of NICU stay were recorded The Outcome parameters used were hospital mortality, the individual mortality risk computed directly from the SAPS II score, the standardized mortality index (SMI observed/predicted death rate with 99% confidence limits), and the ratio of actual to predicted length of stay in the NICU were used. Individual diagnostic categories were considered separately as subgroups. The Receiver operating characteristics curves (ROC) were obtained for SAPS II

Results and Discussion: SAPS II scoring was performed in a total of 387 patients. Forty-four (11.6%) patients (mean age 61 7) died in the NICU. For the whole group, the mean predicted mortality was 15%, and the mortality index 0 77. The mean SAPS II score for surviving patient was 24 points as compared with those who died (47 points) Stratifying SAPS score in different range and comparing with different diagnostic subgroups showed a significant correlation with the mortality rates and the estimated risk of death in the NICU (ROC 0 80–0.89). The mean length of NICU stay for survival patients was 11 days compared to 14 days for patients who died. There were indirect correlationship[2] between SAPS II score and the mean length of NICU stay.

Conclusions: The SAPS II scoring system was an accurate predictor of outcome in a NICU group and can be used for the control of quality assurance for these patients. Additional outcome and therapeutic scores (such as Glasgow coma scale, TISS and MPM) should be associated in order to optimize the quality of health care.

A.11 Study of admissions for iatrogenic disease in a polyvalent intensive care unit

P. Jeanjean, M. Andrejak, M. Ossart, M. Slama. *CHU Nord, 80054 Amiens Cedex 1, France*

Objectives: To evaluate the frequency and to determine the cause of serious iatrogenic accidents (drug-induced or related to a medical or surgical procedure) admitted to our Polyvalente Intensive Care Unit between 1991 and 1996

Methods: The files of all patients admitted to our unit during the study period were independently reviewed by two intensive care physicians. Definite or probable iatrogenic accidents were identified and classified according to their predictability, the possibility of prevention and a possible responsibility (medical, paramedical or none) The following data were compared to those of the general population admitted to the intensive Care Unit. age, sex, IGS, Mac Cabe, Omega, ventilation time and length of stay, number and nature of invasive treatments and mortality

Results: Of the 1,748 patients admitted during the study period, 71 (4 p.cent) were admitted for iatrogenic disease. This group was older (62 ± 17 versus 48 ± 20; $p < 0.0001$), with a more complicated medical history (Mac Cabe = 1 ± 1 versus 2 ± 1; $p < 0\ 0001$), less often ventilated (39 p.cent versus 51 p cent; $p = 0.05$), and more often treated by haemodialysis and haemofiltration (9 p.cent versus 21 p.cent; $p = 0.05$) than the general intensive care population. The iatrogenic accident prolonged the intensive care stay by an additional 421 days. It was fatal in 21 p.cent of cases It was predictable in 8 p cent of cases, and could have been prevented in 68 p.cent of cases. The physician was considered to be responsible in 62 p.cent of cases. The patient's origin had little influence of these parameters Drug-induced iatrogenic disease was more severe (IGS 2 = 42 ± 23 versus 28 ± 22, $p = 0.01$) and was accompanied by a longer stay than events related to medical or surgical procedures (7 ± 10 versus 3 ± 3, p = 0.002).

Conclusion: Iatrogenic accidents represent 4 p cent of intensive care admissions. They are responsible for an excess health expenditure, are largely predictable and could have been prevented in more than one half of cases

A.12 Head injury-induced haemostasis impairment

A. Peyclit, D. Cailloce, P B Petitcolin, G. Pihan, P. Feiss, N Nathan
Department of Anaesthesia, C H U Dupuytren, 2 ave M L King, 87042 Limoges cedex, France

Background and Goal of the Study: Head trauma has been associated with disseminated intravascular coagulation (DIC) Most of these events have been reported specially after opened head injury or when extra-cranial multiple injuries are associated. The aim of this study was to determine if closed head injury is able *per se* to induce DIC and the prognostic role of this DIC

Patients and Methods: 144 patients with head trauma associated or not to multiple injury were included in this retrospective study between January 1995 and December 1996 Sixteen patients were excluded from the study because haemostasis tests or clinical data collection was incomplete (n = 10), the diagnosis of DIC was equivocal (n = 2), because of anticoagulation prior to trauma (n = 1) or death occurring before coagulation test (n = 2) DIC was diagnosed on usual coagulation tests performed 2 2 H after trauma, including prothrombin time (PT < 70%), activated partial thromboplastin time (APTT > 1.3), fibrinogen levels (<1.5 g/l), platelet number (<150 G/l) and D-Dimers level >2 μg/ml, positive ethanol test and major decrease in factor V levels. Patients were classified in 2 groups whether head injury was associated to other multiple injuries (group B, n = 74) or not (group A, n = 55) The severity of injury was classified using the Acute Injury Score (AIS) separating head injury (AIS-head) from other injuries general)[1] Statistical analysis used exact Fisher's test Results are expressed as number of patients or as mean ± SEM, a p < 0.05 was considered significant

Results: Demographic data, time of first coagulation test and volume of perfusion were not different between the 2 groups. Twenty four patients developed DIC during the first 24 H: 4/55 in group A and 19/74 in group B. Erythrocytes were transfused in 2 group A patients and 14 group B patients with DIC. The higher the severity of head injury, the higher was the risk of developing DIC in group A (p = 0.008) and in group B (p < 0.001) (table I). Two of the four group A patients and 9/19 group B patients with DIC, whereas only 0/51 group A (p = 0.004) and 1/55 group B patients without DIC (p < 0.001), died or remained in chronic coma.

Discussion and Conclusion: This study confirms the association of severe head trauma with DIC because blood brain barrier disruption might allow cerebral tissue thromboplastin to enter into the systemic circulation and to trigger DIC. Despite the small number of patients, this study suggests that the occurrence of DIC is a marker of bad prognosis as suggested by the 50% incidence of death or chronic coma in patients with isolated severe (AIS > 2) head trauma with DIC as compared to 8.3% incidence of such events when DIC is absent. When multiple injury and DIC were present, death or chronic coma occurred in 47% of the patients and in only 1.8% in the absence of DIC. This preliminary study suggests the need of a prospective study to evaluate the risk associated to DIC after closed head trauma and questions the use of fresh frozen plasma in the early phase of trauma when cerebral injury may be aggravated by haemostasis impairment.

Table I

Head-AIS		1	2	3	4
Group A	• DIC+	0	0	2	2
	• DIC–	35	4	9	3
Group B	• DIC+	1	4	6	8
	• DIC–	36	10	5	4

A.13 Perioperative silent myocardial ischaemia: an indicator of postoperative morbidity or mortality?

G.W.G. French, Z. Rashid, H. Lam, J.W. Sear, P Foex, S J. Howell.
Nuffield Department of Anaesthetics, University of Oxford, Oxford OX39DU, UK

Background and Goals: SMI occurs in around 31% of patients undergoing hip arthroplasty [1], is independent of the type of anaesthesia used [2] and may predict postoperative morbidity.

Materials and Methods: Patients undergoing major lower limb joint replacement surgery were studied. Past medical history and cardiac risk factors were recorded. Patients underwent ambulatory ECG monitoring (Holter) for 4 days perioperatively, starting on the preoperative night. Three months after discharge, patients were sent a questionnaire enquiring about new cardiorespiratory signs or symptoms. Results were analysed with the χ^2 and *t* tests.

Results and Discussion: 127 patients were studied – mean age 69.9 (SD8.5) years. 87 had risk factors for SMI. 42 patients had SMI perioperatively, 30 of whom had risk factors, the presence of risk factors did not predict the occurrence of SMI

The Mean (SEM) Ischaemic Load (IL) (Mins of SMI per hour monitored) for each day was *0.96* (0 43), *7.04* (2.2), *5.67* (1.54), and *2.64* (1 35) mins per hour. There were no differences between those with and without risk factors The overall ratio of postoperative to preoperative IL was 5.3.1, and the ratio for day 1 to day 3 postoperatively was 7 3 1 Again there was no clear difference between the IL of those with and those without risk factors. 123 responses to the questionnaire were received. There was one death due to bronchopneumonia. There was no difference in morbidity and mortality between those with risk factors and those without. There was an association at three months between new symptoms (chest pain, palpitations, breathlessness or fatigue) and both SMI (p < 0.01) and Ischaemic Load (p < 0.01). There was also an association between new or worsening fatigue and both SMI (p < 0 01) and Ischaemic Load (p < 0 001) New breathlessness was associated with new fatigue (p < 0.001).

Conclusions: The presence of cardiac risk factors did not predict the occurrence of SMI, or adverse cardiac outcome. However, perioperative SMI was associated with increasing postoperative fatigue. The increased SMI on the first postoperative night justifies nursing these patients in a high dependency unit.

A.14 Cardiac troponin I for diagnosis of postoperative myocardial infarction in cardiac surgery

J. Silleran, A. Fiemeyer, M. Paris, J F. Baron. *Department of Anesthesia, Hopital Broussais, Paris*

Postoperative myocardial infraction (PMI) is a major complication following cardiac surgery. The diagnosis may be difficult during the early postoperative period (1) Recent studies have shown that cardiac Troponin I (cTn1) is a highly specific marker of myocardial injury (2) The purpose of the study was to determine whether this assay is more specific and reliable than CKMB for the diagnosis of PMI

Materials and Methods: 265 patients scheduled for valve repair or replacement, coronary artery bypass surgery, or combined surgery were included

C Tn I was measured before cardiopulmonary bypass and 12 and 24 hours after (T12, T24). CKMB was measured on arrival in the ICU, and on the first postoperative day (POD1)

EKG was performed on arrival in the ICU and at least daily up to discharge. New ST segment changes, PMI (new Q waves, akinesia or severe hypokinesia), ventricular arrythmias were considered as postoperative adverse cardiac outcomes.

Results, mean ± SD are compared using Mann-Whitney test (* p < 0.05 significant). ROC curves have been established for cTn1 and CKMB.

Results: 8 patients developed a PMI, 15 ventricular arrythmias, and 26 new ST segment changes. Patients with PMI had a significantly higher cTnI level at T12 and T24 and higher CKMB at POD1 than patients without PMI. Patients with ST segment changes or ventricular arrythmias have also a significant increase in cTnI. Analysis of the ROC curves identified the best diagnosis values for cTn I and CKMB (T12 > 20 ng/ml, T24 > 36 ng/ml, CKMB > 74 UI/l) which indicates patients with a high probability of PMI. We found a 100% sensitivity for cTn1 at T12 and T24, and only 87% for CKMB at POD1. The best specificity was 93% for cTn1 at T24.

	All Patients	PMI (n = 8)	no PMI (n = 257)
T12	19 ± 27	86 15 ± 83 42*	17.92 ± 21 24
T24	16 ± 23	92 58 ± 28 95*	14 3 ± 18 49

Conclusion: C Tn I is more sensitive and specific than CKMB allowing an early and more reliable identification of patients with PMI.

A.15 Postoperative troponin Ic cut-off value is reliable with early cardiac complications after aortic repair

G. Godet, S B Ayed, M A Bernard, C Baillard, M Bertrand, C. Huraux, E. Kieffer, P Coriat *Departments of Anaesthesiology, Biochemistry and Vascular Surgery, Pitié- Salpêtrière Hospital, Paris, France*

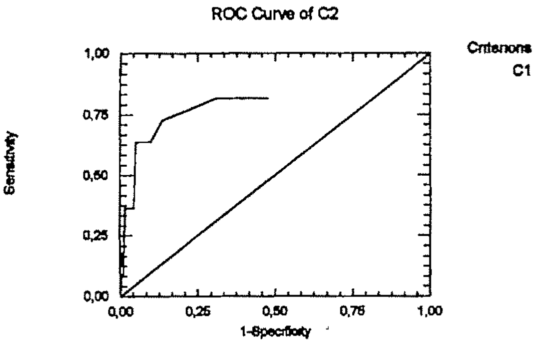
Introduction: Complications of major vascular surgery include unexpected cardiac events which may be predicted by increased Troponin Ic (TnIc) This marker has been reported as sensitive and specific

The aim of this study was to determine the cutoff value of TnIc which may predict cardiac events after aortic surgery.

Methods: 305 consecutive patients undergoing infrarenal aortic surgery were included in a prospective manner Cardiac complications were defined as follows cardiac failure, pulmonary edema, or cardiac death, new Q wave or ST-T depression longer than 48 hours on daily EKG, new akinesia on echography TnIc was dosed within the 1st, 2nd and 3rd postoperative days, using an immunoenzymofluorometric assay on a Stratus autoanalyser (Dade). For evaluation of the ideal discrimination value of TnIc, between the complicated and uncomplicated patients groups, we calculated receiver-operator characteristics for the mean values of the peak of TnIc in the postoperative period.

Results: are reported in the figure

10 patients (3%) developed postoperative cardiac complications 258 patients had TnIc below 0 5 ng/ml, 20 between 0.5 and 1 5 ng/ml and the 27 remaining patients had TnIc higher 1 5 ng/ml



Area under curve is 0 8 (Sd = 0.28) A limit value at 0.6 ng/ml yields to a sensitivity of 73% and a specificity of 86%. A limit value at 1 7 ng/ml yields a sensitivity of 64% and a specificity of 94%

Discussion: A limit value of 0 6 ng/ml is poorly related to cardiac events whereas TnIc level greater than 1.7 ng/ml appears to be correlated with unexpected cardiac events.

A.16 Incidence and causes of cardiac arrests related to anaesthesia in 10 769 administrations

J Dubourdieu, P Biboulet, P Aubas, X Capdevila, Y Ryckwaert, Y Barthelet, F d'Athis *Department of Anesthesiology Hospital Lapeyronie 34059 Montpellier Cedex, France*

Background & Goal of Study: Mortality associated with anesthesia has been extensively studied in several countries. (1, 2)

From the results of these surveys, many anesthesia safety standards have been introducted in Europe It sounds interesting to revalue the incidence and the present time causes of anesthetic cardiac arrests

Materials & Methods: For each of the 101769 anesthesias performed at the University Hospital from 1989 to 1995, were gathered patient identification, ASA physical status, anesthetic technique, possible complications Each time a death was not likely related to the surgery, the medical recorded was refered to. The classification in cardiac arrest totally or partially attributable to anesthesia used the INSERM survey definition. (1) Morever, the classification of cardiac arrests were allocated in preventable or not preventable according to The ASA Closed Claims Study. (3)

Discussion & Results: Among 101769 anesthesias, 11 cardiac arrests related to anesthesia were observed· 7 partially and 4 totally attributable to anesthesia. The cardiac arrest incidence was 1.08 per 10000 anesthesias and the incidence of anesthesia mortality was 0 5 per 10000 anesthesias

The main causes of cardiac arrests related to anesthesia was absolute or relative anesthetic overdose ± associated to hypovolemia (1 case in general anesthesia, 3 cases in spinal anesthesia, 3 deaths), Hypoxemia (2 cases in general anesthesia, 1 death), Hypovolemia isolated (2 cases in general anesthesia, no death), Polyfactorial sudden cardiac arrest (2 cases in spinal anesthesia, 2 deaths), 1 case of Pace Maker dysfonctionment (no death).

No cardiac arrests were noted in recovery room, neither during nerve blocks (n = 9227) Ten of 11 anesthetic cardiac arrests were preventable (Table 1)

Table 1 Cardiac arrests preventale nature of human error

Nature of human error	Number of incidence
Inadequate preoperative assessment	6
Anesthetic overdose	5
Inappropriate monitoring	3
Inadequate fluid replacement	3
Inadequate anesthesia technique	2
Hypothermia	1

The main causes of anesthetic cardiac arrest remain identical to the previous surveys There are no anesthetic cardiac arrest in the post operative period as, all the patients were observed in the recovery room

Conclusion: The human error within the genesis of anesthetic accident seem to be essential It's on this point, that the future efforts should deal to improve the safety in anesthesia

A.17 Morbidity-mortality rates and risk factors after carotid endarterectomy

A.F. Moure, R. Segura, B. Fernández, A Pensado, P Pose *Hospital Juan Canalejo, La Coruña, Spain*

Background and Goal of Study: Carotid endarterectomy (CE) is a prophylactic operation designed to reduce the risk of subsequent stroke and stroke related deaths. As such, the effectiveness of profilaxis is directly related to the perioperative risk operation (1) The purpose of this study is to analize the morbidity and mortality rate after CE and their relationship with the preoperative risk factors

Materials and Methods: 103 patients underwent CE with general anesthesia between January 1991 and February 1997 were retrospectively reviewed. Date were analyzed with logistic regression analysis

Results and Discussion: Patients presented the following risk factors. smoking 61%, hypertension (HT) 57%, peripheral vascular disease 38%, hyperlipidemia 30%, coronary artery disease 33%, diabetes mellitus 25%, arrhythmias 15%, chronic obstructive pulmonare disease 7%, chronic kidney failure 5% and congestive heart failure 4% The mortality rate within 30 days of carotid surgery was 1.9% and severe stroke was 0 9% Postoperative complications were recordered in 50% of patients: HT 30%, hypotension 10 7%, bradicardia 9 7%, cranial nerve injuries (hypogloso, facial or recurrent) 9.7%, transient neurologic syntoms 4 9%, angor 4 9%, respiratory insufficiency 4.9%, arrhythmias 3 9%, convulsions 1.9%, myocardial infarctation 2 9% and severe stroke 0 9% The multivariate analyses showed HT as the only preoperative risk factor related with global postoperative complications and coronary artery disease with the development of postoperative isquemic events.

Conclusions: 1.- HT is the only preoperative risk factor related to postoperative complications following CE. 2.- Preoperative coronary artery disease is related with postoperative isquemics events, the most frequent severe complication after CE. 3 - Despite a relative high postoperative morbidity, the rate of combined mortality and severe stroke morbidity is lower than 3% in our centre, being therefore a beneficial and safe surgery for present-day indications

A.18 Impact of the introduction of a daytime emergency operating theatre in a neurosurgical centre: prospective audit

E V. Addy, C.F. Kearns, N.F Maartens. *Radcliffe Infirmary, Oxford, United Kingdom*

Background and Goal of Study: The National Confidential Enquiry into Perioperative Deaths (CEPOD) is an independent audit undertaken in the NHS which aims to identify potentially remediable factors in anaesthetic and surgical practice. The most recent report[1] recommended a reduction in non-urgent surgery performed out of hours by unsupervised trainees primarily through the introduction of 24 hour emergency operating rooms As we were about to introduce a new daytime emergency operating theatre, we decided to audit our out of hours practice both before and following its introduction

Materials and Methods: A prospective audit of all surgery performed between 1800 and 0800 was undertaken for one month before and one month after the introduction of a day time emergency operating theatre The following data was collected for all cases time of arrival at and departure from theatre suite, patient age and sex, ASA status, operation performed, CEPOD category, seniority of anaesthetist and surgeon involved, and whether surgery could have been safely delayed until day time (non-urgent). Data was analysed using Fisher's Exact test and a value of p < 0 05 accepted as significant

Results and Discussion: There were no differences in patient demographics, ASA status or CEPOD category between the two groups. 13 of the 23 operations performed at night during the first month and 3 out of 19 in the second month were non-urgent (p = 0 01) The most senior anaesthetist present was a trainee for 21/23 cases and 9/19 cases (p < 0 01) and the most senior surgeon was a trainee for 19/23 and 10/23 for the first and second months respectively (p < 0.05)

Conclusions: Following the introduction of a daytime emergency operating theatre there was a significant reduction in the number of non-urgent operations performed at night and a corresponding increase in the seniority of both anaesthetic and surgical staff performing out of hours procedures

A.19 Analysis of documentation of patient data in anaesthetic records in a university teaching hospital

T.K Tan, B A. Crooks. *Glasgow Royal Infirmary University NHS Trust, Glasgow, Scotland*

Background: Anaesthetic Charts are our main record of patient care. Following recent NCEPOD reports (1) and with increasing medical litigation, it is important to audit hospital anaesthetic records.

Aim: To study the quality of information recorded in our hospital's anaesthetic charts and instigate improvements

Method: 124 randomly selected written standard anaesthetic charts (excluding cardiac and obstetrics) from a pool of 66 anaesthetists over a 3 month period, were examined within two days of anaesthesia. Data as suggested by national guidelines (2) were used to assess documentation.

Results and Discussion: The results are shown as a percentage of 124 charts 77% of charts assessed were legible, 23% needed clarification. *Preoperative data.* Patient identification by name, date of birth and hospital number were noted in 97% 96% of patients were seen preoperatively. Only 84% of charts had past anaesthetic details, and if previously anaesthetised in current hospital only 66% of old charts were filed Medical history was noted in 86%, with 43% noting ASA status The fasting status was recorded in 31% Details of airway assessment (56%) and dental state (65%) were poor. A mere 3% recorded height and 14% weight despite their importance. (1) *Intraoperative details:* Only 2 patients out of 3 difficult intubations were Hazard Flagged. 10% charted time of anaesthetic/surgery No charts noted where the patient was anaesthetised or equipment checks 18% noted blood loss. 25% of intubations had grade of larynx noted. 4 records had no vital signs

Conclusion: Anaesthetic records are legal documents They avoid duplication of errors, reflect quality and standard of care. Our study shows deficits in anaesthetic documentation, resulting in incomplete and difficult data retrieval. Poor documentation is difficult to defend legally. Immediate improvement is needed to maintain standards. We suggest emphasis on record-keeping during training, updating and redesigning charts, incorporating national guidelines (2)/checklists. Hazard Flagging in at-risk patients needs standardisation. External assessors from national anaesthetic associations could enforce record keeping to national/legal standards.

A.20 Perioperative infusion of dobutamine: effects of morbidity and mortality

A Donati, D Achilli, R. Coltrinari, D. Battisti, P. Bechi, L. Mariani, S. Caporelli, P. Pietropaoli. *The Dobutamine Group; Institute of Medical and Surgical Emergencies-University of Ancona, Italy*

Background and Goal of Study: Shomaker's study showed a decrease mortality in high risk surgical patients, treated to rich sovranormal values of cardiac index (CI), oxygen avalaibility (DO2I) and oxygen consumption (VO2) [1]. Aim of this study was to see if perioperative infusion of dobutamine, following as therapeutic goal an extimated oxygen extractio (O2ER) lower then 26.7% (the optimal value found by Shoemaker for oxgen extractio [1]) can reduce mortality and/or morbidity in a group of high risk surgical patients

Material and Methods: We have performed a multicentric, prospective, randomized study on high risk surgical patients The protocol study was approved by the Ethic Commitee of Ancona University, Italy. Admission criteria were the same then Shomaker's ones and a written consensus was asked After the admission the patients were radomized in the control or in the protocol group. Before the operation a central vein and a catheter in radial artery were positioned. Controls of emogasanalisis, central venous pressure, arterial pressure, O2ER were made preoperatively, during operation every hour, half an hour after operation, 1, 2, 4, 6, 18 hours after the end of the operation. O2ER was calculated with the following formula. SaO2-SvO2/SaO2. In the control group the therapeutic goal was to achieve normal value of blood arterial pressure and diuresis, while in the protocol group the therapeutic goal was mantain an O2ER < 26 7% In the protocol group if an O2ER higher then 26.7% was found, the following therapeutic steps were made· liquid infusion (blood if Hb < 10 g/dl), then dobutamine infusion (5–15 γ/Kg/min.). At the hospital dicharge a dimmission paper for each patient were organ failures were signed Chi-squared test was performed to show any significative difference in morbidity and mortality

Results: 165 patients were admitted, but of these we have the final data of 135 patients 68 were in the protocol group and 67 in the control group There was no difference in mortality (2 death both in protocol and control group), while a significative difference were shown in number of patients with organ failures (8 in protocol group vs. 20, p < 0.05), total number of organ failures (9 in protocol group vs. 27 in control group, p < 0.01)

Conclusions: These data suggest that maintaining an O2ER higher then 26.7% perioperatively can reduce morbidity in high risk surgical patients

A.21 Effect of thoracic epidural analgesia on postoperative complications after cardiac surgery – a prospective study

D Turfrey, D. Ray, N. Sutcliffe, P Ramayya, N. Scott. *Glasgow University and HCI Medical Centre, UK*

Objective: To assess prospectively the effects of thoracic epidural analgesia on postoperative complications in cardiac surgical patients and the incidence of complications arising from this use of this technique

Method: After gaining informed consent 120 patients were prospectively randomised to receive either thoracic epidural analgesia (TEA) using bupivacaine and clonidine or target controlled infusion (TCI) of alfentanil for analgesia during and after elective coronary artery bypass graft surgery. Anaesthesia was standardised using TCI propofol. Data were collected for the first 5 days and included demographic data, the incidence of complications & time taken to extubation. Results were analysed using χ_2-test on Minitab. Inspiratory volume was measured preoperatively and at 24 hrs postoperatively and the results were compared using the Mann-Whitney U test

Results: No significant differences between the two groups were found with respect to age, sex, ejection fraction, no. of grafts performed, incidence of preoperative respiratory disease, hypertension or diabetes. Bypass and ischaemia times were similar between the two groups Patients undergoing thoracic epidural analgesia were extubated sooner than those using TCI alfentanil (p = 0.05) with a lower incidence of respiratory tract infection (p = 0.048). There were no significant differences between the two groups with respect to other complications or the use of inotropes although this approached significance (p = 0 06) There was a trend for the inspiratory volume to be reduced more in the TCI group although this did not reach statistical significance. 14 patients in the TCI group and 9 in the TEA group were still intubated at 24 hrs and were excluded from this part of the anaylsis There were no serious neurological or other complications arising from the use of TEA in this series of patients.

Conclusion: TEA provides excellent analgesia for the cardiac surgical patient and allows early extubation with decreased incidence of respiratory tract infection in the postoperative period There is also a trend towards decreases in other postoperative complications such as arrhythmias and use of inotropic agents in patients who receive TEA

A.22 Influence of cardiopulmonary bypass-related factors in postoperative renal failure

S. Garrido, M J Martín, A. Toral, P. Rama, S Rodiño, A Figueira. *Department of Anesthesia, Hospital Juan Canalejo, La Coruña, Spain*

Background and Goal of Study: Acute renal failure (ARF) is a serious complication after cardiopulmonary bypass (CPB). Several intraoperative factors are related with the developement of ARF type of flow, hemolysis, hypothermia, duration of CPB, microemboli from CPB, drugs used, hemodinamyc changes etc. The goal of this study is to assess the influence of CPB-related factors in the developement of postoperative ARF

Material and Methods: We evaluate 200 patients undergoing cardiac surgery with total CPB and normal renal function was assessed before the operation. *General patient management.* standard general anesthesia for cardiac surgery was used. CPB was managed with nonpulsatil perfusion Systemic flow was targeted at 2–2.5 l/m/m^2 or 1 6–1 8 l/m/m^2 (normothermia/hypothermia) to mantain a mean arterial pressure of 70 mmHg and 30–70 mmHg respectively. Mannitol was routinely administered *Data collection.* A) CPB information (systemic flow, MAP during CPB, duration of CPB, time of aortic cross-clamping) B) Intraoperative complications C) Hemodynamic values, including pulmonary artery pressures and cardiac output *Statistical analysis·* chi-square, Student's t and logistic regression analysis. *Patient classification:* Class I: patients with ARF (serum creatinine >2 mg/dl); Class II: patients with normal renal function

Results and Discussion: 26 patients developed ARF (13%) Comparing duration of CPB in Class I patients (144.5 ± 84 5 min) with Class II patients (101 2 ± 39 6 min), we observed a statistically significant difference (p < 0 05). Other CPB-related factors did not correlate with the developement of ARF However, the variable "duration of CPB" implies the existence of several surgical and hemodinamyc factors that could be related with postoperative ARF independently of CPB-related factors *per se.*

Parameters of CPB and postoperative renal failure

	Class I	Class II
CPB flow (L/min)	1.98 ± 0.38	2 11 ± 0 38
Duration (min)	144 5 ± 84 5*	101 2 ± 39 6
MAP (mmHg)	64 ± 13 6	71 8 ± 16 5
Ao cross-clamp (min)	83 2 ± 40 9	74 ± 33 2

Conclusion: Among CPB-related factors only the duration of bypass seems to be related with postoperative renal failure This particular factor also involves variables not related to CPB.

A.23 Fast-track recovery in cardiac surgery: experience in a public hospital

H. Litvan, A. Flo, J.M. Campos, J A Fernandez, J. Galan, J. Montiel, A Aris, J M.V. Landeira *Department of Anesthesiology, Hospital de Sant Pau, Hospital Universitari UAB, Barcelona, Spain*

Background & Goal of Study: Fast-Track (FT) recovery is a method to reduce hospital stay (less than 5 days, <5 d) for pacients undergoing cardiac surgery (CS) Based on economical purposes it was started in USA in the 90's. The aims are faster extubation and earlier discharge without increasing morbility or mortality.

Material & Methods: All patients undergoing CS from February to July 1995 with no exclusion criteria (age >70 yr, FVC, FEV1 < 50%, creatinin >147 mmol/l, FEV₁ < 30%, NYHA ≥ 3, patient or family rejection; non elective surgery Preoperative: patient and family information. Anaesthesia: fentanyl <15 μg/Kg with isoflurane or propo. Aprotinin to reduce blood loss and steroids Postoperative early extubation and ambulation. Discharge on specific protocol· stable rythm, Hb > 80 g/l, T < 37.8°C, no ambulation problems, acceptance by patient and family.

Results & Discussion: 229 patients with CPB, 44.5% (102) included in FT No patient rejected to be included. 58 8% (60) were discharged ≥5 d (group A). 41.2% (42) were no suitable (discharge >5 d, group B), 3 9% (4) deaths Preoperatively patients from group A presented less incidence of DM, previous vascular surgery and renal disfunction than group B. There were no significant differences in type of surgery, CPB and aortic clamp times Post-operative complications· 3.4% in group A and 52 7% in group B (p < 0 0005) Statistically significant differences (p < 0 05) were found (A vs B, %) pulmonary (1.6 vs 29), ARF (0 vs 26 3), reoperation (0 vs 13) Also FT statistically significant results (p < 0 005) were (A vs B) extubation time (hours). 6 vs 9, PO-ICU (days) 1 8 vs 3.8, Discharge (days) 4 8 vs 7.7. Causes of discharge delay (%) were inadecuated anticoagulation (26.3), pulmonary (23.7), disrhythmias (18 4), fever (10 5), and neurologic disorders (5 2)

Conclusions: 60% of candidates to FT were discharged before 5 days without any increase in morbility/mortality. Preoperative renal disfunctions and postoperative pulmonary, renal or bleeding complications were discriminatives to delay extubation and discharge Length of stay reduction led to admission of new patients Thus, hospital expenses were increased. FT do not add any savings in our public health system.

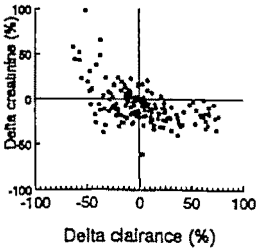
A.24 Serum creatinine cannot predict renal impairment in the perioperative period

A. Zubicki, M.L. Cittanova, K Zaier, C Montalvan, N Nefaa, P Coriat *Department of Anaesthesiology, Pitié-Salpêtrière Hospital, Paris, France*

Background and Goal of Study: Serum creatinine increase is routinely used to detect postoperative renal dysfunction although this parameter is considered by nephrologists to have a poor sensitivity in the detection of renal dysfunction

Material and Methods: We used the 2 h-creatinine-clearance (CC) as a reference method (1). The major issue in the CC determination was the necessity of collecting urine accurately For this reason, patients with anticipated difficulties to perform CC were excluded psychiatric illnesses, prostatic problems. 3 hours before CC measurement, patients were asked to drink half a litter, to obtain a regular output CC measurements were performed between 12 h and 17 h to minimise diurnal variations All the procedure was checked by a physician 182 patients scheduled for aortic surgery, without CPB, (120 aneurysms, 62 stenosis) were analysed, mean age 66 ± 10 years (Males n = 164) Serum creatinine and CC were measured in the preoperative period and at day 7 Renal impairment was defined as a 20% increase in serum creatinine or a 20% decrease in CC

Results and Discussion: Considering CC, 28 patients (15%) had a renal impairment in the postoperative period, as compared to 13 patients (7%) considering serum creatinine Serum creatinine sensitivity was 0 46 (CI 95%. 0 37–0 55); its specificity was 0 99 (CI 95%: 0 98–1 00). Figure I shows the poor correlation between serum creatinine and CC modifications, Spearman test R = 0 50.



Conclusion: Serum creatinine increase has a low sensitivity in renal impairment diagnosis in the perioperative period. The use of CC is therefore mandatory in clinical studies assessing risk factors for renal dysfunction

A.25 Patient knowledge of anaesthesia and perioperative care in an Irish teaching hospital

J. Laffey, M. Coleman, J. Boylan *Dept. of Anaesthesia, St Vincent's Hospital, Dublin 4, Ireland*

Background and Goal of Study: Recently the public has taken an increasing interest in medicine. However, its perception of anaesthetic care and the role of anaesthetists appears to remain limited (1, 2) Inadequate understanding of medical terms may limit the validity of informed consent and compromise the value of the preoperative visit We examined patient knowledge and attitudes concerning perioperative care and the role of the anaesthetist and determined what, if any, improvement in patient knowledge occurred during an elective inpatient stay

Materials and Methods: Following ethical approval, 300 patients answered a multiple choice questionnaire asking them meanings of commonly used medical terms, knowledge of anaesthesia and expectations and fears concerning surgery, pain and anaesthetic care. Patient groups were surveyed either before their preoperative visit, after the visit, or after surgery.

Results and Discussion: Knowledge of commonly used terms including fasting, drips, catheters, nasogastric tubes, and their functions was limited 25% of patients believed that oxygen was an analgesic or antiemetic These deficits were not improved by preoperative visiting or postoperative ward exposure Patients' understanding of the role of the anaesthetist in their perioperative care was similarly limited, although this improved during hospital stay. Only 49% of patients surveyed prior to preoperative assessment knew that anaesthetists were medically qualified This increased to 72% after the visit but declined to 64% postoperatively, with similar findings for anaesthetists' role in intraoperative and recovery care, demonstrating the transience of the knowledge acquired. Comparable proportions of patients admitted to fear of surgery, postoperative pain, awareness, and death Females and young patients feared awareness most In general, female, younger, higher SE group patients had greater knowledge and expectations

Conclusions: Patient knowledge concerning perioperative care remains limited and improves only marginally during hospital stay If increased patient participation is to be realised it will require novel approaches to patient education.

A.26 Unintended decreasing body temperature: a stepchild of perioperative care and outcome consequences

R. Uebelen, K. Schulze, D. Müller, H. Rückoldt, M. Bund, S. Piepenbrock.
Dep. of Anaesthesiology, Medical School Hannover, Germany

Background & Goal of Study: Recent sudies indicate an association between hypothermia, increased blood loss, increased morbidity rates, longer hospitalization and increased mortality rates (1, 2). The purpose of this study was to prospectively evaluate whether perioperative decreasing body temperature is a problem in our surgical patients and whether it influences postoperative outcome.

Material & Methods: On admission at our ICU the rectal body temperature of 207 surgical patients was used to form four groups. All patients were scored by POSSUM. The POSSUM score defines the severity of illness following admission to the ICU and allows a more precise prognosis for the patients population to be assessed before treatment commences. Complications, the length of stay and the survival/death on the ICU were documented.

Results & Discussion: Perioperative hypothermia of patients during major surgery is frequently observed in our hospital. Only 23.6% of our patients were admitted with core temperatures over 36.0°C. The groups did not differ with regard to the POSSUM-predicted morbidity or mortality. In contrast we observed elevated incidences for morbidity and mortality from mild hypothermia to severe hypothermia. These differences were significant for mortality (p = 0.0031/Chi-squared analysis with Fisher's exact test). In addition hypothermia was an independent predictor for mortality by multivariate analysis of variance (p = 0.0087).

Group	(%)	Temp. (°C)
1 (n = 049)	23.6 Normothermia	>36.0
2 (n = 116)	56.0 Mild unindended hypothermia	35.9 – 34.0
3 (n = 038)	18.3 Moderate unintended hypothermia	33.9 – 33.0
4 (n = 004)	1.9 Severe unintended hypothermia	<33.0

Group	Lenghth of stay (days) mean/Range	Complication-rate (%) predicted/observed	Mortality (%) predicted/observed
1	4.51/2–30	20.0/24.0	6.0/8.2
2	4.15/1–29	18.0/18.0	4.9/0.9
3	5.97/2–37	21.7/18.0	7.7/16.0
4	3.75/2–9	29.6/25.0	9.4/25.0

Verification of the isolated influence of unintended hypothermia is only possible if the preoperative risk and surgical management is comparable in both, the normo- and hypothermia group. Comparing groups with the same score-predicted risk, this is the first prospective study showing that unintended hypothermia results in an increased postoperative mortality, and that hypothermia is an independent predictor for postoperative mortality.

Conclusion: Our data suggest that maintaining patients normothermia means to improve patients outcome.

A.27 Single-dose antiemetic treatment of postoperative nausea and vomiting in the recovery room is insufficient

L.H.J. Eberhart, A.M. Staack, A.M. Morin, M. Georgieff, W. Seeling.
Department of Anaesthesiology, University of Ulm, Germany

Background: Postoperative nausea and vomiting (PONV) is a frequent problem in the recovery room and on the surgical ward [1]. This prospective, epidemiological study determined the relationship between early occurrence of PONV in the recovery room on the patient's outcome on the ward.

Methods: During a 4-month period 1000 patients undergoing a wide variety of surgical procedures were observed in the recovery room for the occurrence of nausea and vomiting and then followed up postoperatively for a period of further 24 hours.

Results: The total incidence of PONV was 36.4%. 165 patients (16.5%) suffered from PONV in the recovery room. 128 of them (77.6%) were treated with antiemetics (metoclopramide, dimenhydrinate, droperidol, and tropisetron). After complete relief of PONV, patients were transferred to the ward (median times in the recovery room: patients with PONV: 100 min; patients without PONV: 75 min). There however, 331 suffered from PONV. Patients who have previously shown symptoms in the recovery room had more than a 4fold increased risk for PONV later on the ward (see table). Furthermore these patients suffered from more severe PONV than patients who developed PONV only later on the ward.

There was a trend towards a lower rate of reappearance of PONV in patients who were trated with longer acting antiemetic drugs (droperidol, tropisetron) or received a prophylactic antiemetic treatment with repeated doses of shorter acting drugs (metoclopramide, dimenhydrinate).

Recovery room	Surgical ward
Without PONV (n = 835):	remained syptom-free: 76.2%
	developed new PONV: 23.8%
With PONV (n = 165):	were cured from PONV: 20.0%
	had persistent PONY: 80.0%

Conclusion: Patients suffering from PONV in the recovery room have a very high risk for persistant severe PONV on the surgical ward, even when their antiemetic treatment in the recovery room has been successful.

Thus, in these patients, longer acting antiemetics should be prefered to treat PONV in the recovery room. Otherwise, when short acting antiemetics are used, their administration should be repeated to ensure effective plasma levels of the drug.

A.28 Multifactorial treatment including ondansetron eliminates postoperative nausea and vomiting

K. Zając, M. Zając, A. Ciaćma. *Department of Anesthesiology and Intensive Care, Jagiellonian University, Kraków, Poland*

Background and Goal of Study: Nausea and vomiting is a "big little problem" after gynaecological surgery [1]. This study compares the effectiveness of metoclopramide and dexamethasone vs metoclopramide, ondansetron and dexamethasone in the prevention and treatment of PONV in patients premeditated i.v. with droperidol scheduled for total abdominal hysterectomy (TAH).

Materials and Methods: 410 patients ASA 1 and 2 received at the induction of general anaesthesia 1 mg droperidol i.v., then. fentanyl, thiopentone and suxamethonium following 3 min oxygenation. Anaesthesia was maintained with 66% nitrous oxide in oxygen, halothane up to 0.5 vol% and atracurium; on pain stimuli fentanyl was added. IPPV ventilation supplied patients with 10 ml/kg of tidal volume via endotracheal tube. At the end of surgery the patients were blindly randomized to be administered i.v. either metoclopramide 10 mg plus dexamethasone 8 mg or the same doses of metoclopramide and dexamethasone and 4 mg ondansetron. All the incidents of PONV were recorded by the nursing staff hourly for 12 hrs. Data were analyzed using chi-square test; p < 0.01 was considered statistically significant.

Results: Age, weight, height and duration of anaesthesia were similar between the groups. Postoperatively none of the 205 patients of the ondansetron group showed any evidence of vomiting.

	Group without ondansetron	Group with ondansetron
Number of patients	205	205
No PONV	127 (62%)	200 (97.6%)
Nausea >10 min	12 (5%)	2 (0.9%)
Vomiting	21 (10%)	0 (0%)

It appears that the synergistic, multifactorial therapy of PONV enhanced with ondansetron can be highly effective in N2O and fentanyl supplemented anaesthesia for major gynaecological surgery (p < 0.001) [2].

Conclusion: Ondansetron in a single i.v. dose of 4 mg in combination with droperidol, metoclopramide and dexamethasone actually eliminates PONV.

A.29 Sixty per cent of patients can be extubated in the operating room after orthotopic liver transplantation

E. Cerutti, G. Massano, R. Romagnoli, E. Castenetto, M. Schellino, F. Gennari, G. Fagiano, M. Salizzoni. *Liver Transplant Center, San Giovanni Battista Hospital-Turin, Italy*

Background & Goal of Study: Improvements in surgical technique of orthotopic liver transplantation (OLT) and experience with severely ill patients led us to explore the possibility and safety of extubating OLT recipients in the operating room (OR)

Material & Methods: From 01/1995 to 09/1997, 248 OLTs were consecutively performed in 227 patients The piggy-back technique without veno-venous by-pass was routine (>95% of the cases) OR extubation was performed within 90 minutes after the end of surgery Its feasibility was jointly evaluated by the anesthesiologist and the surgeon, according to these criteria haemodynamic stability without active bleeding nor amine use, adequate graft function (improvement of coagulation tests and base deficit), absence of encephalopathy, no use of antagonist drugs except for neuromuscular reversal Data are expressed as mean ± SEM

Results: 149 OR extubations were performed in the 248 OLTs (60%) The rate of OR extubation increased with time (1995 49%, 1996 61%, 1997: 74%). Preoperative features of OR extubated patients were a) age. 48 ± 1 years (range 16–67), with 73 patients aged more than 50, b) UNOS status· I (patient at home, active), 18 patients (12%), II (at home, with frequent hospital interactions), 106 patients (71%); III (continuous hospitalization in acute care bed), 25 patients (17%), IV (life expectancy <7 days), no patient Intraoperative features were a) surgical time 351 ± 7 minutes (range 165–545), b) total blood requirement 8 5 ± 0 5 PRBC units (range 0–32), with 39 patients receiving >10 units, c) final PaO_2/FiO_2 ratio· 442 ± 9 (range 161–705); d) final body temperature always >36°C The time to OR extubation averaged 29 ± 2 minutes Forty-five OR extubated patients (30%) were discharged directly to a surgical middle care unit Only one patient was reintubated within 24 hours because of oversedation and hypercapnia

Conclusions: OR extubation after OLT is feasible and safe in 60% of the patients Contrarily to what previously suggested[1], age >50 years, UNOS III status and total blood requirement >10 PRBC units do not preclude OR extubation This practice is an effective alternative to prolonged postoperative sedation and can reduce the need of intensive care hospitalization in OLT recipients

A.30 Preoperative risk factors for postoperative renal impairment after aortic surgery

M L Cittanova, K Zaier, N Dieudonné, A Zubicki, B Riou, P. Conat
Department of Anaesthesiology, Pitié-Salpêtrière Hospital, Paris, France

Background and Goal of Study: The development of postoperative renal failure is a serious complication occurring in 1–50% patients, depending on the population studied (1). The aim of the study was to prospectively assess preoperative risk factors for a postoperative renal impairment

Material and Methods: We defined a renal impairment as a 20% decrease in creatinine clearance (CC) between the preoperative and the postoperative (day 7) period. 245 scheduled patients for aortic surgery were enrolled in the study over a 2 year-period Non scheduled patients, planed CPB, chronic extrarenal epuration were excluded. The following preoperative variables were considered. sex, age, coronary disease, hypertension, left ventricular ejection fraction, radiocontrast agents administration, angiotensine converting enzyme inhibitors (ACEI) use, diuretics use, respiratory insufficiency, renal disease, diabetes mellitus, hyperuricemia, cerebral vascular disease, cancer, preoperative serum albumin, haemoglobin and calcium concentrations and peroperative variables· surgery duration, sepsis, peroperative hypotension, aprotinine administration, transfusion, colloid and crystalloid loading A forward stepwise logistic regression (criteria for entry, $P < 0\ 05$) was used, odds ratio and 95% confidence interval (CI) were calculated

Results: Extrarenal epuration was required in 3 patients in the postoperative period. Postoperative renal dysfunction occurred in 59 (24%) patients. Only preoperative ACEI use (odds ratio· 1.93, 95% CI 1–3 77) was significantly associated with postoperative renal impairment

Conclusion: We therefore concluded that postoperative renal impairment, defined as a 20%-decrease in CC, was significantly related to one preoperative predicted factor ACEI use.

A.31 Anaesthetic morbidity during laparoscopic surgery

D. Milon[1], A. Rauss[2], H. Musellec[3], M Gentili[3], F. Bonnet[4]. *And the ARAR[5]. [1]Dept Anaesth. Hôpital Sud, 35000 Rennes; [2]Labo Roussel Uclaf, 93235 Romainville; [3]CMC Saint-Vincent 35763 Saint-Grégoire; [4]Dept Anaesth. Hop Tenon, 75970 Paris; [5]Association pour la Recherche en Anesthésie Réanimation, France*

Laparoscopic surgery is extensively used and is reported to be safe. However insufflation of the abdomen by CO_2 significantly impairs respiratory and cardiovascular function and may have deleterious side-effect We therefore conducted a multicentre epidemiologic survey to assess anaesthetic morbidity related to laparoscopic surgery

Patients and Methods: The study was prospectively conducted over one year in 25 surgical centres All the patients scheduled for laparoscopic surgery during this period were included Data were collected from a predetermined questionnaire which focused on patients features, type of surgery, monitoring, and complications They include ventilatory (e g pneumothorax) cardiovascular (e g severe hypotension or cardiac arrythmia) and surgical (e.g haemorrhage) complications An univariate analysis and then a step by step logistic regression were used to determine the risk factors of complications

Results: 2610 patients were included in the study and 493 (18.9%) suffered from at least one complication. Among the 582 complications, 54% were surgical ones, 23 7% were respiratory and 18 7% were hemodynamic ones Univariate analysis pointed out 17 factors significantly associated with complications, 7 of these persisted as independent risk factors (RF) in the multivariate analysis (table).

RF	OR	95% CI	P
Type of surgery	2 39	1 53–3 74	<0 00001
centre	6 77	3 86–3 74	<0 00001
ASA	1 78	1 35–2 35	<0 00001
Chronic respiratory failure	2 46	1 38–4 39	<0 00001
Weight	1 82	1 21–2 74	<0 0021
Sex (w)	0 7	0 56–1 01	<0 04
Insufflation pressure	1 45	1 04–2 02	<0 06

According to our model, we were able to adequately classify 66% of the patients in complicated or uneventful surgery Using the first 4 risk factors of this model allowed to predict an adjusted risk varying between 1 44 and 70 8

This study documents that close to 1 over 5 patients scheduled for laparoscopic surgery experience at least one adverse event The rate of complication is highly influenced by the type of surgery but it is also independently related to the surgical centre. This risk can be predicted according to patient physical status

A.32 Early morbidity and mortality and risk factors in patients undergoing lung resection for lung carcinoma

E. del Barrio, G Varela, M Jiménez, I Torán, P G Cosmes, C Muriel
Hospital Universitario de Salamanca, España

Background and Goal of Study: Morbidity and mortality rates for pulmonary resections remain significant Morbidity ranges from 7 to 50 percent, and mortality from 2 to 12 percent, despite advances in anaesthesia, surgical techniques and perioperative care. Cardiac and pulmonary complications are the major sources (1, 2)

The aim of the study was to evaluate the early morbidity and mortality rates in patients undergoing major pulmonary resection for lung carcinoma, and to identify risk factors

Materials and Methods: One hundred and ninety nine patients underwent pulmonary resection (lobectomy and pneumonectomy) for lung cancer between December 1994 and September 1997 were retrospectively reviewed The following were recorded Age, sex, ischemic cardiopathy as a risk factor, tumoral stage, surgical procedure, preoperative evaluation of respiratory function and perioperative complications (only if a medical intervention was required).

Mortality risk asociated with selected factors was evaluated using multiple logistic regression analysis

Results and Discussion: 199 patients, 186 males and 13 females, were studied (70 pneumonectomies and 129 lobectomies) The median age of patients was 63 years (range 35–6) ASA score II–III. Twenty four patients (12%) presented previous ischemic cardiopathy Perioperative complications were absent in 143 patients (72%) Forty three patients (22%) had postoperative pulmonary complications and 21 patients (10%) cardiac complications There were seventeen postoperative deaths (8 5%) Patients with a preoperative FEV1 less than 50% of predicted had a mortality rate of 33% and complications occurrence in 66% There were no intraoperative deaths. In a multivariate analysis, none studied factor seems to be predictive about occurrence of death FEV1/FVC appears to be the best high risk indicator.

Conclusion: Our results suggest that preoperative risk factors such as ischemic cardiopathy and pulmonary function should not deny the pulmonary resection Occurrence of perioperative complications is associated with an increased risk of death Pulmonary complications continue to be the major source of morbidity.

A.33 Rate of lower respiratory tract infection in intensive care units: an Italian multicentre observational study

G. Sangiorgi[1], M. Antonelli[2], E. Manso[3], A. Brienza[4], A. Gasparetto[2], E. Magliano[5], G. Martinelli[1], G. Montanari[6]. [1] *Ist. Anest. & Rian.-Università "S. Orsola" (Bo);* [2] *Ist. Anest./Rian.-Università "La Sapienza" (Roma);* [3] *Labor. Microb.-Osped. Le Torrette (An);* [4] *Ist. Anest./Ter. Inten/Rian.- Policlinico (Ba)* [5] *Labor. Microb. Ospedale Niguarda Milano;* [6] *Ist. Anest./Rian Gubbio (Pg), Italy*

Introduction: The current problems/controversies on epidemiology and management of hospital-acquired infections are of particular concern for patients admitted to intensive care unit, for which severity of illness, length of hospital stay, invasive diagnostic procedure and appropriate treatment could represent, among other, risk factors in the development of severe respiratory complication.

An Italian Observational Study in Intensive Care Unit and relative Microbiological Department has been planned to mainly investigate in ventilated ICU patients:

(a) Rate & Characterisation of bacterial infection at low respiratory level
(b) Pattern of antibiotic susceptibility

Preliminary general data are here presented.

Methods: 36 ICU Centres in collaboration with their respective Microbiological Dpt. participated to the study. According to common protocol criteria and a 3 months study period, consecutive admitted ICU ventilated-patients have to be observed for 7 days. A 1st microbiological sampling was obtained on admission to the ICU by means of a protected bronchial catheter (Combicath®); a 2nd sampling was similarly performed in still ventilated Pts. at 7th day or prior in those subjects which developed pneumonia. All samples were evaluated for pathogen identification, CFU value and antibiotic testing. Data on admission diagnosis, former antimicrobial therapy and in-out patient provenance were also collected.

Results: Up to now 557 cases are included in the study. 367 of them (66%) were in-patient, previously hospitalized in surgery (42%) or in other Clinical Dpt: almost 1/3 came from emergency room. On ICU admission 60% of the Pts were already intubated, for an average length period of 6.4 hours. At 1st sampling, colonizations (24.2%) or infection (13%) occurrence were respectively observed. Among longitudinally evaluated pts, 57 (10.2%) developed a LRT complication, nearly 38% of them within day 2 following ICU admission. *S aureus* (20), *Pseudomonas aer.* (11), *Acinetobacter spp* (4), *Haemophilus spp* (3), *neg coag S* (3) were the most frequently observed pathogens.

OUTPATIENT ANAESTHESIA

A.34 Inhalational induction for day-case anaesthesia: patient and anaesthetists' acceptability

A.J. Byrne, A.S. Wolverson. *Queens Medical Centre, Nottingham, NG7 2UH, UK*

Background and Goals of Study: Sevoflurane offers the opportunity for potentially beneficial inhalational induction (IHI) in daycase surgery[1], despite this its use appears limited. The aim of this study was to determine views of anaesthetists and patients on IHI and to compare its use with our current standard technique for daycase anaesthesia.

Materials and Methods: Questionnaire surveys of daycase pts. *(n = 150)* & anaesthetists *(n = 95)* were carried out together with a prospective randomised open two group study of pts. undergoing daycase gynaecological surgery *(n = 24). Group 1:* Sevoflurane induction/maintainence. *Group 2:* propofol induction/sevoflurane maintainence Patient acceptabilty, morbidity & recovery characteristics were studied. Results were compared using a chi squared test

Results and Discussion: 47% of pts. preferred IV induction (IVI), 44% had no preference & 9% preferred IHI. Of pts. who had had previous GA (77% of total), 98% found IVI acceptable, compared with only 43% for IHI.

Of anaesthetists surveyed, none used IHI as the method of choice in adult pts, the primary indication for IHI being airway difficulties (98%), 71% considered pt. choice an indication. The most commonly believed disadvantage was pt. unacceptability of the technique (83%). Over 80% of anaesthetists would choose to use sevoflurane for IHI. Randomised comparison with IVI showed a much improved pt. accepability of IHI (100% accepability in both groups) and comparable morbidity (see table) & recovery charateristics. PONV and dizziness were increased in IHI, but this was not statistically significant possibly due to the small sample size.

	PONV	Headache	Dizziness	Somnolence
Group 1*	4	4	5	2
Group 2*	1	4	3	2

*$n = 12$

Conclusion: IHI was perceived to be an unpopular choice by pts. and anaesthetists alike. However when compared in the randomised study, IHI with sevoflurane appeared as acceptable to pts. as IVI. Bias against IHI amongst anaesthetists and pts. may continue to restrict the use of this potentially beneficial technique.

A.35 Propofol *vs* sevoflurane in short surgical gynaecological procedures

A. Suarez, E. Guasch, I. Fornet, A. Longarela, F.J. Palacio. *Servicio Anestesiología, Reanimación Hospital Universitario "La Paz", Madrid, (Maternidad), Spain*

Background and Goal of Study: Propofol induced anesthesia and manteinance is a well studied and safe technique for short gynecological surgery.(1) Experience with Sevoflurane, in U.S.A. and Europe, has shown it as an alternative because it's a safe and rapid drug for induction and manteinance of anesthesia.(2) We have compared both techniques (intravenous and inhalatory) and a combined one with propofol and Sevoflurane.

Material & Methods: We have studied 50 patients scheduled for short gynecological procedures and randomized in 3 groups: Group 1: Propofol induction 2.5 mg/Kg and manteinance at 5–6 mg/kg. Group 2: Propofol 2.5 mg/kg and Sevoflurane 1–2% for manteinance. Group 3: Sevoflurane for induction (vital capacity technique) and manteinance 1–2%. All patients were ventilated with O2/N2O at 40/60 and laringeal mask was applied. All patients received prior to induction Fentanilo at 1–2 μgr/kg. We excluded pregnant patients, morbid obesity, liver or kidney disease, or surgery in previous 7 days and ASA >II. Standard monitorization

Results and Discussion: All groups were homogeneous. We didn't find significative differences in induction times or laringeal mask insertion between groups 1&2 vs 3. We didn't find significative differences neither in induction characteristics nor in haemodinamic stability among three groups. There are significative differences in quality of inmediate awakening between groups 1&2 vs 3 (nausea, vomiting) and 24 hours after surgery ($p < 0.05$). Patients of group 3 had more pain 2 hours after surgery ($p < 0.01$), but we didn't find differences 24 hours pain.

Conclusion: Induction with Sevoflurane is an alternative for the anesthesiologist but we conclude it increases the incidence of nausea and vomiting in patients scheduled for ginecological surgery and the patients feel more pain at the inmediate postoperatory period.

A.36 A double blind comparison of sevoflurane *vs* propofol and mivacurium for tracheal intubation in day case wisdom tooth extraction

A. Thwaites, I. Smith. *Keele University, North Staffordshire Hospital, Stoke-on-Trent, UK*

Background and Goal of Study: Propofol and mivacurium are commonly used in day case anaesthesia but both drugs have adverse effects. Sevoflurane provides a rapid, smooth induction, acceptable to the majority of patients[1] and permits tracheal intubation,[2] but has not been compared with an iv induction-muscle relaxant technique.

Materials and Methods: 24 (ASA I–II) patients undergoing day case wisdom tooth extraction were randomly allocated to receive propofol-mivacurium-isoflurane or sevoflurane. After obtaining written consent an iv cannula was sited and oxygen (5 L min^{-1}) was delivered by facemask. After 1 min, fresh gas flows were changed to oxygen, 2 L min^{-1}, and N_2O, 4 L min^{-1}. The inhalation induction group received 8% sevoflurane with manual ventilation after loss of consciousness until intubation. The iv induction group received propofol 2–3 mg kg^{-1}, isoflurane, 1%, and mivacurium, 0.2 mg kg^{-1}. Nasal intubation was performed at 4 minutes, in both groups, by a blinded anaesthetist and conditions were graded using the Krieg and CCC scores. All patients received ibuprofen and bupivacaine infiltration for analgesia. Time to start of IPPV, completion of intubation and emergence times were recorded. NIBP was measured prior to induction and at 1 minute intervals. Average costs were calculated using UK prices. Data (mean ± SD or median and IQR) were analysed by ANOVA, nonparametric and Fishers exact tests, as appropriate.

Results and Discussion: The two groups were demographically comparable. Intubation was completed at 281 ± 62 s and 293 ± 52 s with propofol-mivacurium and sevoflurane, respectively. Intubation scores and conditions did not differ significantly between the groups (table). MAP was significantly higher in the iv group at 7 (104 ± 15 *versus* 88 ± 16 mmHg) and 8 min (104 ± 18 *versus* 79 ± 13 mmHg) compared to the sevoflurane group. Emergence times were similar (table). Based on actual drug used to complete intubation, the sevoflurane technique cost significantly less at £5.77 *versus* £6.80.

	Propofol-mivacurium	Sevoflurane
Kneg score	3 (3–5)	4.5 (3.5–6.5)
CCC; Clinically. acceptable (n)	11	11
unacceptable (n)	1	1
Eyes open (min)	6.0 ± 2.3	5.1 ± 1.0

Conclusion: This study shows that providing adequate induction times are used, sevoflurane induction provides comparable intubating conditions and is cheaper than a propofol mivacurium technique. However, a larger sample would be required to detect uncommon side effects.

A.37 Sevoflurane *vs* propofol in day-case surgery anaesthesia

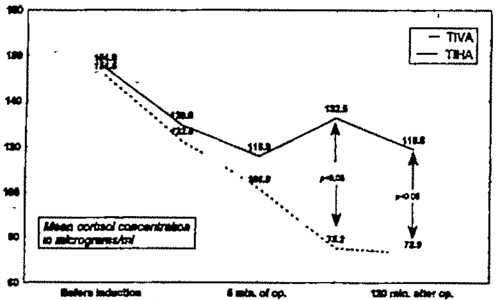
N. Kokot, S. Rzymski, M. Gaca. *Department of Anaesthesiology and Intensive Care, Szpital MSW, Poznań, Poland*

Goal of Study: Comparison of two different method of general anaesthesia in day-case surgery.

Materials & Methods: 60 women; aged 18–60 yrs; ASA I or II. Operation: excision of cystic mammary displasia. Oral premedication: midazolam. Group A – TIVA (induction: propofol 1.5–2.0 mg/kg + alfentanyl 7 μg/kg; maintenance: propofol by Prys-Roberts rule + alfentanil 1 μg/kg/min.); group B – inhalation anaesthesia "TIHA" (induction. sevofluran 7% vol + 50% O_2/N_2O; maintenance: sevofluran 1–2% vol + 35% N_2O/O_2). Patients breathing spontaneously via laryngeal-mask. Ventilation was supported when apnea >15 s. occurred, tachypnoe was >30 and MV decreased more than 30% of baseline. We measured: the number of patients needing ventilation support (Supp. Vent.), awakeing time (Aw. T.), response time (Res. T.), orientation time (Orient. T.), discharge time from recovery room (Disch. T.), home ready time (Home Ready T.), p-deletion test and cortisol concentration. Side effects were reorded. Postop. pain was treated with NSAID-s.

Results: There were no significant differences in p-deletion test and vomiting/nausea. Side effects (TIVA v. TIHA; $p < 0.05$): pain (20% v.70%), dizziness (6% v.60%), sedation-VRS >0 (10% v 0), apnea (6% v.0) and drowsiness (50% v. 14%). Other results are shown in the tabele ($p < 0.05$).

	Group A	Group B	
Supp. Vent	n = 30	n = 21	$p < 0.05$
Aw T. (min.)	5.7 ± 2.64	4.7 ± 1.97	ns
Res T. (min)	6.8 ± 2.85	5.4 ± 1.91	$p < 0.05$
Orient T. (min)	7.9 ± 3.08	6.1 ± 2.09	$p < 0.05$
Disch T. (min)	33.2 ± 6.75	21.7 ± 5.17	$p < 0.05$
Home Ready (min)	137.3 ± 21.73	73.7 ± 13.73	$p < 0.05$



Conclusions: 1. In both groups ventilation support was applied. 2. In TIHA group patients needed pain treatment more frequently and earlier than in TIVA group. 3. TIHA (sevofluran + N_2O/O_2) is safe and comfortable for patients and they could be transferred from recovery room to DCS dep. quicker than after TIVA (propofol + alfentanil).

A.38 Sevoflurane *vs* propofol for ambulatory anaesthesia: a cost-effectiveness analysis

N. Nathan, A. Peyclit, A. Lahrimi, P Feiss *Department of Anaesthesia, C H U. Dupuytren, 2 ave. M.L. King, 87042 Limoges cedex, France*

Background & Goal of the Study: Inhaled induction and maintenance of anaesthesia with sevoflurane (S) in adults is as safe and reliable than with IV propofol (P). This prospective randomised study compares the cost and the adverse events during and after induction and maintenance of ambulatory anaesthesia either with S either with P.

Patients & Methods: Fifty two, ASA I female adult patients scheduled for pregnancy termination by curettage were included after CPPRB approval and written informed consent. After premedication with lorazepam. 1 mg, 2 hours before surgery, anaesthesia was induced with 0.5 to 0.75 mg alfentanil and either P (2–3 mg/kg), (n = 26) either with S (8%, 6 l/min O2) (n = 26) using the single breath vital capacity technique. Anaesthesia was maintained with N_2O in both groups and either 20 mg P boluses either S (2 to 3% in 2 1 fresh gas flow) according to the clinical signs of depth of anaesthesia. Standard cardiovascular and respiratory monitoring data were recorded each 2 min after the start of anaesthesia. The doses and length of administration of gas and anaesthetics were measured to calculate the cost. The delay of induction (loss of eyelash reflex, fixed pupils), the time to respond to verbal command, to say one's name and birth date after the end of administration of N_2O (group P) and S (group S) were measured. Adverse events were prospectively recorded during anaesthesia and in the recovery room. Patients were asked to answer to a detailed questionnaire about their subjective feeling at the exit of the recovery room and at the 24th postoperative hour. A Fisher's exact test or a chi-2 test were used to compare non parametric data. An anova test was performed with parametrical results. Results are expressed as mean ± SEM. $P < 0.05$ was considered significant.

Results: The demographic data, the length of anaesthesia and stay in the recovery room were not statistically different between the 2 groups (not shown). The loss of eyelash reflex occurred faster in the sevoflurane group (35 ± 3 sec vs 56 ± 5 sec, $p < 0.05$). No ventilatory adverse events occurred at induction and were of same incidence during the maintenance of anaesthesia. The mean arterial pressures were not different between groups but the heart rate was slower in group S during anaesthesia (not shown). 14/26 patients moved during anaesthesia in group P whereas only 4/26 in group S ($p < 0.05$). The incidence of postoperative vomiting was increased in the sevoflurane group ($p < 0.05$) The patients felt able to perform a normal activity after the same delay (18.4 ± 2.9 H vs. 20.6 ± 2.8 H, $p > 0.05$) and the percentage of unpleasant feeling in the per and postoperative period was the same between groups. The total cost of anaesthesia (syringe, anaesthetic agents and medical gases) was lower in group S (679 FF for 24 patients vs. 1153 FF for 25 patients). Four patients had to be reoperated in group S because of uterine haemorrhage (none in group P) The weight of aspiration product in the last 26 patients was higher in group S (293 ± 66 g) as compared to group P (108 ± 8 g, $p = 0.004$).

Discussion & Conclusion: The single breath induction with 8% sevoflurane allows a faster induction and a more reliable depth of anaesthesia when associated to premedication and opioids. Emesis was more frequent in group S but of short duration which did not preclude the discharge of the patient nor their return to a normal activity The risk of uterine haemorrhage is of concern in patients receiving sevoflurane and further investigations concerning blood loss in obstetrics are warranted. For other ambulatory, surgery, anaesthesia with sevoflurane is a good alternative to propofol

A.39 Postoperative nausea and vomiting in day-case arthroscopy patients

M.B. Hough, B. Sweeney. *Department of Anaesthesia, Poole General Hospital, Poole Dorset BH15 2JB, UK*

Background and Goal of Study: We have studied the effects of 2 different inhalational agents in arthroscopy surgery in order to quantify the differences in nausea and vomiting.

Materials and Methods: After ethical committee approval and informed consent 156 ASA I–II patients, undergoing day-case arthroscopy surgery were allocated to a balanced anaesthetic technique, differing only in the type of volatile agent utilised Patients were induced intravenously with propofol (3–4 mg/kg) and fentanyl (1–1.5 μg/kg). Then utilising a spontaneously ventilating technique the patient was exposed to either desflurane (76 patients) or isoflurane (80 patients) in 33% oxygen and nitrous oxide. Pain, nausea and vomiting were assessed. The categorical data was analysed with a Chi-square test and contingency table (statistical significance if p-value was less than 0.05).

Results and Discussion: 18 patients experienced postoperative nausea, 14 of these were in the desflurane and 4 in the isoflurane group of patients ($p < 0.05$). The recovery profile of desflurane has been previously studied in a variety of settings (1, 2). Whilst nausea has been previously reported as an incidental finding (3), our study shows a clear association with desflurane compared with isoflurane.

Conclusion: This study shows a significantly higher incidence of PONV in the patients receiving desflurane compared with isoflurane in a day-case population undergoing knee arthroscopy.

A.40 Propofol autocoinduction in ambulatory anaesthesia

P. Ribes-Pastor, G. Djaiani. *Department of Anaesthesia, Morriston Hospital, Swansea, UK*

Background & Goal of Study: Propofol as the sole induction agent significantly decreases arterial blood pressure. Addition of midazolam reduces the induction dose of propofol[1] but delays psychomotor recovery of patients in postoperative period[2]. The aim of this study was to compare post-induction haemodynamic effects and recovery times from anaesthesia using three different co-induction techniques.

Material & Methods: 36 ASA I & II outpatients admitted for minor orthopaedic surgery were randomly allocated to receive alfentanil 10 $\mu g.kg^{-1}$ 2 min prior to induction followed by either midazolam (M) 0.05 $mg.kg^{-1}$ or propofol (P) 0.4 $mg.kg^{-1}$ or saline (S) 2 ml. After 2 min P infusion was commenced at a rate of 50 $mg.kg.^{-1}h^{-1}$ until loss of eyelash reflex. Laryngeal mask airway (LMA) was inserted. Mean arterial blood pressure (MABP) was noted at 1 min intervals starting before the first injection until LMA was in situ. Anaesthesia was maintained with O_2/N_2O/Isoflurane. Times for eye-opening after surgery (EOAS) and discharge-readiness (DR) were recorded. The maximum percentage reduction in MABP was calculated. Data was analysed using ANOVA ($p < 0.05$). Results are expressed as mean values ± standard deviation.

Results & Discussion: All groups were comparable for age, sex, weight, ASA status and duration of surgery. There was significant difference between the groups in total dose of P required, reduction of MABP following induction of anaesthesia and discharge readiness from hospital in favour of the auto-co-induction i.e. P + P technique (table 1).

Table 1

Variables/Groups	S + P	P + P	M + P
Reduction in MABP (%)	22 ± 4.7	14 ± 3.2	15 ± 3.6
Time EOAS to DR (min)	142 ± 16	124 ± 11	174 ± 24
Dose of P per patient (mg)	183 ± 25	129 ± 17	105 ± 25
Cost per induction/patient	£3.55	£2.5	£2.3

Conclusions: P + P reduced undesirable cardiovascular effects of S + P, shortened discharge times from the hospital compared to M + P and reduced overall cost per patient.

A.41 Remifentanil *vs* fentanyl in ultrashort gynaecological day surgery

M. Mulas, D. Sances, E. Sabbia, G. Pala, P. Ruiu. *Institute of Anesthesiology and Critical Care University of Sassari,*

Background and Goal of Study: Remifentanil (Remi) is an esterase metabolized opioid with a short elimination half-life (1) (2). The purpose of this preliminary study (Institutional approval request) is to verify if Remi may be used, in single-shot administration, so to obtain a good analgesia free from side effects in cases of gynaecological day-surgery not exceeding 10 min.

Materials and Methods: Fourty patients similar in terms of age, height, weight, ASA status, duration and type of surgery were randomized (double blind) into two Groups: Remi or Fentanyl (Fenta). The patients, pre-medicated with 0.4 mg of atropine, and pre-oxygeneted for 3 min., have been anaesthetized by bolus of propofol as follows: 50 mg in bolus + 10 mg every 10 sec. up to loss of consciousness. In the first Group analgesia has been secured by Remi in dosage 1 μg/kg (3); in the second by Fenta 1.5 μg/kg. Further doses of propofol have been administered when needed. All patients underwent surgery, in spontaneous breathing, while being monitorized on ECG, FC, PAS, PAD, PAM, Sat. O_2. Time of emergence was registered, together with presence or absence of anaesthesia side effects; pain was mesured by VRS both at emergence and after 30 min.

Results and Discussion: Emodynamic stability has resulted analogous in both Groups; Sat. O_2 has never appeared inferior to 97%. Group Remi has been administered a lower dose of propofol. As the Table shows, emergence and recovery of mental performance intervened slightly earlier in Group Remi. Post-operatory pain detected by VRS has proven more intense in the Remi Group, in accordance with its half-life.

	Remifentanil	Fentanyl
Operation length	9.4 ± 3.15*	10.15 ± 2.39*
Propofol used	169 ± 25*	189 ± 32*
Eyes opening	2.5 ± 1.76*	2.4 ± 2.16*
Reply to order	2.5 ± 1.67*	2.8 ± 2.12*
Date of birth	2.95 ± 1.95*	3.58 ± 2.12*
Discharge operatory room	5.23 ± 2.40*	6.01 ± 3.20*
Pain at emergence	1.1 ± 0.8**	0.2 ± 0.4**
Pain after 30 min.	1.5 ± 1.0**	1 ± 0.9**
Post-operatory nausea	1 case	2 cases

*mean and standard deviation **VRS

Conclusions: Our results indicate that analgesia induced by Remi in single-shot proves satisfactory in ultra-short surgicals operations.

A.42 Target-controlled remifentanil in combination with propofol for spontaneously breathing day case patients: effects on respiration

J.A.C. Murdoch, R.A. Hyde, G.N.C. Kenny. *University Department of Anaesthesia, Glasgow Royal Infirmary, Glasgow, UK*

Background and Goal of Study: Remifentanil is a new ultra short acting opioid. As with other potent opioids it causes a dose dependent respiratory depression[1]. We, therefore, aimed to establish an appropriate range of target plasma concentrations which would allow anaesthesia, with adequate spontaneous respiration, in combination with propofol in a day case setting.

Materials and Methods: 20 unpremedicated adult patients undergoing day case surgical procedures were studied. A target-controlled infusion of remifentanil (concentration 20 μgml^{-1}) was started at a target concentration of 1.6 $ngml^{-1}$ and anaesthesia induced with a target-controlled infusion of propofol. A laryngeal mask was inserted and ventilation assisted as required to maintain an end tidal CO_2 ($EtCO_2$) between 6.5–7.0 kPa and an arterial oxygen saturation >95%. After surgical incision the propofol target was reduced to 4.5 μgml^{-1} and the remifentanil target concentration increased or decreased in increments of 0.2 $ngml^{-1}$ until adequate spontaneous ventilation to an $EtCO_2$ 6.5–7.0 kPa was achieved for a period of at least 5 minutes. The target plasma concentration of remifentanil which achieved this was noted.

Results: In only 12 of the patients studied was adequate spontaneous ventilation maintained for a full 5 minute period. In this group the target remifentanil concentration ranged from 0.6–2.8 $ngml^{-1}$ with a median of 1.6 $ngml^{-1}$ (Fig). This corresponded to infusion rates of 0.019–0.107 $\mu gkg^{-1}\ min^{-1}$ with a median of 0.050 $\mu gkg^{-1}\ min^{-1}$.

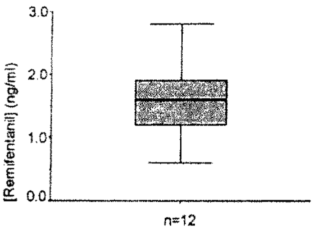

Fig. remifentanil target plasma conc ng/ml
median; interquartile range; range

Conclusions: Adequate spontaneous respiration using a combination of target-controlled remifentanil and propofol proved to be a difficult technique with only a 60% success rate, within the constraints of our protocol. The range of target concentrations which achieved this varied over a 4.7 fold range around a median of 1.6 $ngml^{-1}$. A controlled ventilatory technique might, therefore, be more appropriate.

A.43 Rapid recovery from anaesthesia with remifentanil and isoflurane, enflurane or propofol may enable more inpatient, short surgical procedures to be performed as day-cases

J.-P. Muller[1], F. Chung[2], J. Scholz[3], H Breivik[4], M. Araujo[5], K. Hjelle[6], B. Upadhyaya[7], C. Haigh[7]. *[1]AZ SINT JAN OCMW, Belgium; [2]Toronto Hospital, Canada, [3]UKE Hamburg, Germany; [4]Rikshospitalet; [6]Glaxo Wellcome, Norway; [5]Hospital de Santo Antonio, Portugal; [7]Glaxo Wellcome R&D, UK*

Background and Goals of Study: Remifentanil (R), is a highly potent, μ-receptor selective, esterase-metabolised opioid with a half-life of 8–10 minutes[1]. This international study investigated the effects of R with isoflurane (I), propofol (P) or enflurane (E) upon the quality of anaesthesia and recovery in day-case or in-patients undergoing identical surgical procedures. Because of R's short duration, post-operative nausea and vomiting (PONV) was additionally assessed. The intra-operative outcomes have been presented elsewhere.

Materials and Methods: Following ethics approval and signed consent, 854 patients (445 day-case and 409 in-patients), ASA class I–III undergoing gynaecological laparoscopy, varicose vein or arthroscopic surgery were randomised to R & I, R & E or R & P. Induction proceeded with R and P followed by routine muscle relaxation. After tracheal intubation, anaesthesia was maintained with R infusion and I or E at 0.5 MAC or R and P infusion at 100 μg/kg/min. Intra-operative NSAID ± wound infiltration with local anaesthetic provided post-operative analgesia. PONV was managed with routine anti-emetics.

Results and Discussion: Extubation and recovery of respiratory function occurred within median times of 5–7 minutes after end of anaesthesia. PONV, recovery room (RR) and hospital (Hosp.) discharge results are presented below

Endpoints (All times in minutes)	R + I (N = 285)	R + E (N = 285)	R + P (N = 284)
Median anaesthesia duration	53	53	52
Anti-emetics Day/In-Pt (%)	16/15	17/21	5/14
Day Patients – Median time	(N = 148)	(N = 149)	(N = 148)
RR discharge qualification	34	35	30
Actual RR discharge	75	72	76
Hosp discharge qualification	161	167	146
Actual Hosp discharge	248	225	228
Nausea (%)/Vomiting (%)	19/8	17/9	13/3
In-patients – Median time.	(N = 137)	(N = 136)	(N = 136)
RR discharge qualification	35	37	36
Actual RR discharge	68	64	66
Hosp discharge qualification	1319	1250	1211
Actual Hosp discharge	1773	2592	1797
Nausea (%)/Vomiting	24/15	23/13	11/31

Conclusions: R with I, E or P provided extremely stable anaesthesia and consistent recovery. PONV was much lower in the R&P group suggesting this combination may be useful in patients at risk of developing these symptoms. The consistently short RR discharge times for day-case and in-patients suggests that more institutions may be able to consider accommodating current, in-patient, short surgical procedures on a day-case basis.

Supported in part by a grant from Glaxo Wellcome

A.44 Remifentanil and desflurane – an ideal combination for rapid recovery?

A Biedler, W. Wilhelm, K. Berg, A Langhammer, C Bauer, R. Larsen
Klinik für Anaesthesiologie und Intensivmedizin Universitatskliniken des Saarlandes 66421 Homburg/Saar, Germany

Background and Goal: For clinical use the new opioid remifentanil must be combined with another anaesthetic agent. Propofol, well established for ambulatory anaesthesia, appears to be the first choice. However, the properties of desflurane (low blood-gas solubility, rapid elimination) suggest this volatile anaesthetic at least as a comparable alternative [1]. The goal of this study was to compare the recovery times after anaesthesia with remifentanil in combination with either propofol or desflurane.

Materials and Methods: With institutional approval and written informed consent 40 gynaecological patients (ASA status I–II) scheduled for elective laparoscopy were studied at random. All patients received 5 mg diazepam p.o. at least 1 h prior to surgery. Anaesthesia was induced with remifentanil 1 μg/kg followed by remifentanil infusion (0.5 μg/kg/min) and propofol 1–2 mg/kg. For maintenance remifentanil was reduced to 0.25 μg/kg/min five minutes after intubation and combined with either propofol 0.1 mg/kg/min or 0.5 MAC (3 vol%) desflurane in O_2/air With termination of surgery anaesthetic delivery was discontinued simultaneously and recovery times were recorded. Statistical significance ($p < 0.05$) was proved with Mann-Whitney-U-test, all data are presented as mean ± SEM.

Results: Both groups (desflurane n = 20, propofol n = 19) were comparable in respect of demographic data, anaesthetic dosages, and duration of anaesthesia and surgery Recovery times were significantly shorter for remifentanil desflurane than for remifentanil propofol.

Time to [min]	Remifentanil Desflurane	Remifentanil Propofol	p value
Spont ventilation	6.4 ± 0.6	9.6 ± 0.9	0.01
Extubation	6.7 ± 0.6	9.8 ± 0.9	0.02
Open eyes	6.5 ± 0.6	9.8 ± 0.9	0.01
State name	7.2 ± 0.6	10.6 ± 1.0	0.02
PACU arrival	11.1 ± 0.8	14.7 ± 1.0	0.005

Conclusions: Emergence after 0.25 μg/kg/min remifentanil is more rapid when combined with 0.5 MAC desflurane than with 0.1 mg/kg/min propofol Regarding the recovery times, this study demonstrates that desflurane is a suitable adjunct to remifentanil and an alternative to propofol, particularly for ambulatory anaesthesia. Differences are best explained by the pharmacological properties of both co-anaesthetics, their applied dosages, and their different interaction with remifentanil Clinical experience gained hitherto suggests that for both co-anaesthetics a further dose reduction is possible, depending on the surgical procedure

A.45 Blood alcohol concentration and psychomotor effects on skills associated with driving

S. Grant[1], G.N.C Kenny[1], K Millar[2] *[1]Glasgow University Department of Anaesthetics, Glasgow Royal Infirmary, Glasgow, [2]Glasgow University Department of Psychological Medicine, Gartnaval Royal Hospital, Glasgow G12 0XH, UK*

Background & Goal of Study: Fitness to drive following ambulatory anaesthesia is a current topic of debate The only legal standard which exists for fitness to drive while under the influence of a drug is that of blood alcohol concentration (BAC) Our goals were to assess impairment occurring with intravenous infusions of alcohol at the 3 European legal standards of 20, 50 and 80 mg 100 ml^{-1} BAC and use this as a standard by which anaesthetics can be compared.

Materials & Methods: We compared an oral dose of alcohol 0.75 $mg.kg^{-1}$ with an intravenous infusion designed to achieve 20, 50 then 80 mg 100 ml^{-1} BAC in 12 healthy volunteers. Subjects were given 0.75 $ml.kg^{-1}$ alcohol diluted in fruit juice to drink and when their BAC decreased to 20 mg.100 ml^{-1} an infusion of 5% alcohol commenced. Breath analysis of BAC was used to control the infusion rate and maintain a steady BAC for 30 mins each at 20, 50 then 80 mg.100 ml^{-1}. Psychomotor performance was assessed by tests of choice reaction and a dual attention task. Parametric data were analysed using ANOVA. $P < 0.05$ was regarded as significant.

Results & Discussion: At the 20 mg. 100 ml^{-1} target the mean BAC was 22.1 mg.100 ml^{-1} (SD 3.7), at 50 mg 100 ml^{-1} it was 51.5 mg 100 ml^{-1} (SD 3.3 mg.100 ml^{-1}), and at 80 mg 100 ml^{-1} was 80.5 mg 100 ml^{-1} (SD 4.2 mg.100 ml^{-1}). This compared to the oral dose where the peak ranged from 19 to 68 mg.100 ml^{-1} In psychomotor testing, choice reaction time showed significant differences between the 50 and 80 mg 100 ml^{-1} conditions and baseline ($P < 0.05$) In dual task, secondary reaction time showed a statistically significant difference between all groups and baseline ($P < 0.05$) while tracking showed a significant difference between the 50 and 80 mg groups and baseline ($P < 0.05$)

Conclusion: Oral dose gives widely variable BACs which makes it difficult to make reliable assessments of impairment An intravenous infusion enables the investigator to maintain the blood alcohol concentration within a narrow range. This allows reliability and precision when investigating the effects of alcohol on psychomotor performance.

A.46 Blood propofol concentration and psychomotor effects on skills associated with driving

S. Grant[1], J. Murdoch[1], K. Millar[2], G N C. Kenny[1] *[1]Glasgow University Department of Anaesthetics, Glasgow Royal Infirmary, Glasgow, [2]Glasgow University Department of Psychological Medicine, Gartnaval Royal Hospital, Glasgow G12 0XH, UK*

Background & Goal of Study: Fitness to drive following ambulatory anaesthesia is an important issue. In previous work we have investigated the decrement in performance seen with blood alcohol concentration (BAC) at the 3 European legal permitted limits for driving of 20, 50 and 80 mg.100 ml^{-1}. The aim of this study was to compare impairment in psychomotor performance seen following propofol infusion with that occurring at the legal limits for driving under the influence of alcohol

Materials & Methods: Informed consent was obtained from 6 healthy volunteers and baseline recordings of psychomotor performance made. An infusion of propofol was commenced at a target concentration of 1 μg.ml^{-1} and increased incrementally until the subjects were heavily sedated. The target was then reduced and maintained at 0.8, 0.4 and 0.2 μg.ml^{-1} for 30 mins each while the subject performed 3 psychomotor tests which were repeated twice at each level. The tests employed were choice reaction time, dual task tracking with secondary reaction time and within list recognition memory. Parametric data were analysed using ANOVA and non-parametric using Krushall-Wallis. $P < 0.05$ was regarded as significant.

Results & Discussion: The propofol concentration required to produce sedation varied from 1.4–3 μg.ml^{-1}. ANOVA did not reveal any significant differences between the 3 doses of propofol using choice reaction time but examination of 95% confidence intervals revealed a difference between 0.8 μg.ml^{-1} and baseline. The mean deterioration at 0.8 μg.ml^{-1} was 107 ms^{-1} ($P < 0.05$). ANOVA revealed a significant difference between groups in secondary reaction time ($P < 0.05$). Subsequent analysis of confidence intervals revealed there to be a significant difference between 0.8 and 0.4 μg.ml^{-1} and baseline. The mean deterioration seen was 187 and 85 ms^{-1} respectively. The results presented here when compared to previous work with alcohol reveal a greater degree of impairment seen at 0.8 μg.ml^{-1} propofol than at a blood alcohol concentration of 80 mg.100 ml^{-1}. When the blood propofol falls to a target of 0.4 μg.ml^{-1} the impairment seen in psychomotor testing is less than observed at 50 mg.100 ml^{-1} BAC and at 0.2 it is less than even 20 mg.100 ml^{-1} BAC.

Conclusion: Low dose propofol caused minimal deterioration in psychomotor testing. The impairment seen was less than that observed at the permitted legal driving limits of 20, 50 & 80 mg.100 ml^{-1} (Sweden, France and UK respectively).

A.47 Assessment of balance using computerized dynamic posturography after day-case anaesthesia for nasal surgery

M.G. Parry, H. Glaisyer, P. Bailey. *Department of Anaesthetics, Royal National Throat, Nose and Ear Hospital, London, UK*

Background & Goal to Study: Simple clinical tests of postural stability after day case surgery are inadequate when assessing the suitability of patients for discharge. Computerised dynamic posturography (CDP) is a technique which allows a quantified assessment of integrated balance control(1). The aim of the study was to assess balance prior to discharge using CDP in adult patients undergoing elective day case nasal surgery.

Materials & Methods: 22 patients were recruited and each received a standard anaesthetic of fentanyl 1 μ.kg^{-1}, propofol 2–3 mg.kg^{-1}, atracurium 0.5 mg.kg^{-1}, diclofenac 100 mg PR and an oxygen/nitrous oxide mixture with 1–1.5% isoflurane. Paired CDP study data was collected for each patient at baseline (pre-op), 1.5 hour and 3 hours after termination of anaesthesia. CDP testing consisted of a sensory organisation test (SOT) and the movement coordination test (MCT). The SOT consists of six stages:- 1) SOT1- eyes open with forceplate and visual surround fixed; 2) SOT2- eyes closed with forceplate fixed; 3) SOT3- eyes open with visual surround sway-referenced and forceplate fixed; 4) SOT4- eyes open with forceplate sway-referenced and visual surround fixed; 5) SOT5-eyes closed with forceplate sway-referenced; 6) SOT6- eyes open with visual surround and forceplate sway-referenced. Paired student's *t* test was used for statistical analysis of CDP data and $P < 0.05$ was considered significant.

Results & Discussion: Two patients had to withdraw from the study due to post-operative nasal haemorrhage. No significant difference was detected between the baseline versus the 1.5 or 3 hour SOT equilibrium scores (%) and the MCT latencies (ms).

	Baseline	1.5 hour	3 hours
SOT1	95.4 ± 1.8	94.9 ± 2.1	95.3 ± 1.6
SOT2	92.8 ± 3.0	91.8 ± 3.3	93.1 ± 2.6
SOT3	89.9 ± 4.3	86.9 ± 6.3	88.7 ± 4.1
SOT4	85.9 ± 6.7	86.5 ± 7.2	87.9 ± 6.8
SOT5	67.8 ± 10.8	65.5 ± 11.4	71.0 ± 8.0
SOT6	62.5 ± 12.0	64.2 ± 15.2	67.5 ± 10.6
MCT	149.0 ± 15.7	148.2 ± 13.2	143.8 ± 10.7

Conclusion: In day case nasal surgery patients receiving a standard anaesthetic technique, CDP testing failed to detect any significant impairment of integrated balance control at 1.5 and 3 hours post-operation.

A.48 Predicting factors from unanticipated admission following ambulatory surgery

M.J. Linares, M.D. Pelegrí, F. Pi[1], E. Izquierdo, L. Parra, P. Gambús, A. Abad, F. Sanchez, R. Masia. *Anaesthesia Dpt, Hospital de Viladecans;* [1]*Surgery Dpt., Viladecans Hospital Barcelona, Spain*

Background and Goal of the Study: Hospital admission following ambulatory surgery is a valid measure of morbidity and a quality indicator. To improve the adecuate direction of an ambulatory surgery unit it is essential to study that factors associated with unexpected hospital admission. Our goal was to analyze the association of age, ASA, type of surgical and anesthetic procedures, surgical duration, pain, vomiting and surgical and anesthetic complications with unexpected admission following ambulatory surgery in our setting.

Methods: Design used was retrospective case-control study for the reason that, unexpected hospital admission is a rare event. The subjects studied were, all patients subjected to ambulatory surgery in the Viladecans Hospital from October 1990 till May 1996 (N = 6071). This cases ($n_1 = 93$) were obtained from admission records for ambulatory surgery. Controls ($n_0 = 552$) were selected at random from all patients without being admitted. Logistic regression models with a predicative variable and multiple logistic regression were obtained Odds Ratio and its corresponding 95% CI were calculated in order to analyze the relationship between risk factors and hospital admission.

Results and Discussion: Our results agree with Gold[1] according to surgery time, emesis and divergence according to age, ASA and general anaestesia.

Association of factors with admission. Initial logistic analysis/multiple logistic regression

Factor	Odds Ratio initial/multiple regression logistic	95% CI initial/multiple regression logistic
Age	0.99	0.9–1.9
ASA > I	0.99/3.44*	0.4–2.2/1.36–0.072
Laparoscopy	6.51*/1.01	2.2–19/0.12–8.27
Abdominal surgery	5.06*/0.76	1.7–14/0.08–7.54
Proctological surgery	5.61*/34.64*	1.9–16/3.94–304
21 to 40 minutes	8.29*	2.44–28
> to 41 minutes	7.44*/22.37*	3.7–14/5.33–93
TIVA	6.80*/3.31	3.6–12/0.39–27.9
Inhalatory	1.66/0.6	0.6–4/0.04–9.9
Rachidian anaesthesia	2.69*/1.01	1.2–5.7/0.19–5.2
Rachidian anaesthesia with profound sedation	20.76*/19.9*	8.9–48/3.25–122
Dolor	17.42*/12.4*	6.9–43/2.79–55
Vomiting	5.37*/8.4*	1.7–16/1.21–59
Surgery complication	37.6*/58.0*	19–73/20–165
Anesthetic complicat.	35.1*/138*	11.6–106/26–729

*$p < 0.01$

Conclusions: surgical and anesthetic complications, proctological surgery, rachidian anaesthesia with profound sedation, pain and surgery time more than 40 minutes were main predictting factors for unexpected admission in ambulatory surgery.

A.49 Patients' experiences of day surgery

T. Kangas-Saarela, J. Ohukainen, M. Koivuranta. *Department of Anaesthesiology, University of Oulu, Finland*

Background & Coal of Study: Day surgery patients are well followed concerning pain and nausea during their stay at the hospital, but little is known after they leave the unit. To assess the quality of our care and patients' overall satisfaction we made a survey.

Patients & Methods: 217 patients were randomly selected for a telephone interview by an anaesthesiologist on the following day. Patients were asked about the presence and intensity of nausea, vomiting and pain or any other untoward symptom, use of pain medication and overall satisfaction of their experience. An 11- point rating scale (0–10) was used for assessment of nausea and pain.

Results: Ten patients (4.6%) of the original study group were admitted to the hospital. Four patients were not reached by phone. Thus the survey was completed with 203 patients.

65% had orthopaedic lower limb surgery, 11% hand surgery and 24% general surgery. 54% were women and 46% men. 85.7% had ASA 1 and 12.3% ASA 2 status. Spinal anaesthesia was used in 65%, general in 21%, intravenous regional anaesthesia in 10% and brachial plexus, epidural or local infiltration anaesthesia in 4%. Nausea was experienced by 5.9% of all patients during their stay at the hospital, one patient was vomiting Tree patients were treated with antiemetics. After discharge 12 patients (6%) had experienced nausea. Only one had taken antiemetic medication at home. 11.3% (23.3% after general and 6.8% after spinal anaesthesia) had nausea during their whole day surgery experience.

21 patients (10.3%) had no pain during the first 24 hours after discharge 10 patients (4.5%) rated their overall pain very severe (point 9 or 10). At the time of the interview 63 patients (31%) had no pain, three patients still rated pain very severe. 28.1% had taken no pain medication 27 patients had headache after discharge. 22 of these had had spinal anaesthesia, 3 needed blood-patch 14 patients (0.6%) after spinal anaesthesia reported spontaneously pain in the lower limbs or back.

182 patients were very pleased and 21 fairly pleased to their day surgery experience None of the patients was dissatisfied.

Conclusions: During the first 24 hours after discharge most of the patients were pleased and feeling well with only little discomfort Nausea and vomiting was not a problem, but postoperative pain treatment needs further evaluation The provision of analgesics and adequate information for their use at home is crucial for all patients

A.50 Day case laparoscopic cholecystectomy: the anaesthetic experience

R.G Miller, E A Clements, M Virdi, J.M. Wellwood *The Plane Tree Centre, Whipps Cross Hospital, Leytonstone, London, E11 1NR, UK*

Background & Goal of Study: Laparoscopic cholecystectomy is increasingly being performed as day case surgery. This study reviewed the anaesthetic method and experiences of patients after hospital discharge to determine if this is safe, feasible and acceptable.

Materials & Methods: Unselected patients taken from one surgical waiting list were booked for day case laparoscopic cholecystectomy Each patient was routinely screened pre-operatively by nursing staff. The surgery was performed by a consultant surgeon and two higher surgical trainees

A standardised anaesthetic technique was used: premedication with temazepam, metoclopramide and ranitidine if required; induction with glycopyrrolate, midazolam, fentanyl, propofol, ondansetron; intubation using atracurium, and maintenance with isoflurane and 66% nitrous oxide in oxygen. A nasogastric tube was inserted Two litres of iv fluids were given Analgesia included 100 mg diclofenac and 1 g paracetamol PR with additional fentanyl as required and 0.5% plain bupivacaine to the port sites. Post-operatively further diclofenac was given and if necessary one dose of IM morphine, followed by oral analgesia

Patients were discharged by the nurses using standardised criteria and given written and verbal information The patients were telephoned on the day after surgery and followed up one week later

Results & Discussion: A total of 60 patients (one was unsuitable due to unstable diabetes) were studied over 5 months The average age was 52 years

Mean surgical time was 62 minutes (26 to 166) The average time to discharge was 6 hr 2 min There were 11 overnight admissions (18%); 3 anaesthetic, 4 surgical (one open cholecystectomy) and 4 social admissions One patient was re-admitted for a retained stone

10 (21%) of those who had been day cases said that they would have preferred an overnight stay.

Average post-operative use of co-proxamol was ten tablets

Conclusions: This study demonstrated that by use of a standardised anaesthetic technique including multimodal analgesia, laparoscopic cholecystectomy can be successfully and safely carried out as a day case with a high degree of patient satisfaction. Overnight facilities should however be available

A.51 Bispectral analysis of the EEG to compare the hypnotic effects of inhalation (sevoflurane) *vs* intravenous (propofol) anaesthesia induction in day surgery patients

E. Van Den Eeden, C De Deyne, M. Struys[1], J P. Schiepers, J. Deghislage, E Vandermeersch[2], R. Heylen. *Depts of Anesthesia, ZOL Sint-Jan, Genk; [2]University Hospital UZG, Gent, [2]University Hospital Gasthuisberg, Leuven, Belgium*

Previous studies revealed that an empirically derived bispectral EEG measure, the bispectral index (BIS), is a significant predictor of depth of anesthesia. The goal of this study was to compare pharmacodynamic characteristics of induction (rapidity of onset and depth of anesthesia) of inhalation vs intravenous anesthesia as measured by bispectral index

Methods: Following local ethical committee approval, sixty, unpremedicated ASA I or II patients, aged 18 to 70 years, scheduled to undergo elective hysteroscopic procedures were studied Patients were randomly allocated to receive inhalation or intravenous anesthesia induction For inhalation induction, a deep breath inhalation induction with sevoflurane was applied. After priming of the respiratory circuit and after a deep expiration, patients were asked to inhale deeply 8% sevoflurane in a mixture of O2/N2O (35/65%) For intravenous induction of anesthesia, propofol 2.5 mg/kg bw was injected over a 15 sec period Bispectral EEG monitoring was performed in a bifrontal referential montage using an Aspect-1000 EEG monitor.

Results: Both groups were demographically similar with no differences between them in terms of age, weight or heigth The time to loss of consciousness in the pts receiving propofol (mean 57 sec SD 13 sec) was not statistically different from pts receiving inhalation induction with 8% sevoflurane (mean 48 sec SD 17 sec) In both groups, the decrease in BIS started at the same time as the loss of consciousness, with the minimal BIS occurring at a mean of 40 sec later Comparing the depth of induced anesthesia, by comparing the minimal BIS values, there was no significant difference between intravenous and inhalation induction (propofol mean BIS 32, SD 14, sevoflurane: mean BIS 28, SD 12)

Conclusion: Bispectral EEG analysis revealed that 8% sevoflurane deep breath inhalation offers equal conditions of anesthesia induction (concerning onset and depth of anesthesia) as intravenous propofol induction.

A.52 Comparison of three methods of inhalation induction with sevoflurane in adults

J Rodrigo, R Martin-Larraun, J I Gómez, P. Vila, G Blanc, A Biarnés, L Usán. *Spanish Sevoflurane Study Group, Spain*

Background and Goal of Study: This multicenter study compares 3 induction methods with sevoflurane in nitrous oxide 66%. Different concentrations (8%, 4.5%[1]) with the vital capacity (VC) method and incremental induction (1% increase every 3 breaths) at normal tidal volume (ITV)

Materials and Methods: After Ethics Committee approval, written informed consent was given by 121 adult ASA I–II patients undergoing short procedures (<90 min). Fentanyl (1 μg/kg iv) was given before induction Patients randomly received VC8, VC4.5 (prefilled circuit, Philip et al [2,3]) or ITV After loss of lash reflex, sevoflurane was fixed at 4.5% until LMA placement. Times to loss of lash reflex and voluntary movement were assessed. Side effects and easiness of LMA insertion were recorded After, patients evaluated quality of induction Values of $p < 0.05$ were considered as statistically significant (* in table below)

Results and Discussion:

Table 1 Time to induction indicators, seconds [mean ± SE]

Group	N	Lash reflex	Voluntary movement
VC8	42	67.9 ± 7*	62.3 ± 7.5*
VC4.5	39	98 ± 7.5	88.3 ± 7*
ITV	40	115.7 ± 6.1	111.9 ± 6.1*

There were no significant differences in time to loss of lash reflex between VC4.5 and ITV, but the ANOVA (Bonferroni correction) shows tendencies in that direction. 19% of patients had side effects; most frequent were secretions (8.2%) and excitement (5.7%), with no significant differences between groups

LMA insertion was easy in 85.1% of cases Only 6.7% considered induction unpleasant, and 94.2% would repeat the same technique (no significant differences between groups). There were no hypoxic episodes ($SpO_2 < 90\%$)

Conclusion: VC8 is the fastest method, with no increase in side effects More time is needed to instruct the patient and prefill the circuit Induction with sevoflurane in adults, with any of the three described methods, is fast and safe. It permits easy placement of LMA and provides a high degree of patient satisfaction.

Supported by Abbott Laboratories, S A (Spain).

A.53 Cost minimization comparison of sevoflurane compared with propofol and isoflurane in gynaecological day-case surgery

Ian M McMenemin, Thomas B Lytle, Stephen J Coles. *Dept. of Anaesthesia, Western Infirmary, Glasgow, G11 6NT, Abbott Laboratories, Norden Rd, Maidenhead, Berkshire, SL6 4XE, UK*

Background: The use of the propofol for induction coupled with isoflurane are currently the most commonly used agents for day surgery. Sevoflurane is readily acceptable for inhalational induction as well as maintenance[1] The purpose of this study was to compare the costs of sevoflurane only with a propofol isoflurane technique and relate these to advantages for both patients (morbidity, acceptability) and the hospital (anaesthesia and recovery times).

Methods: 40 ASA I–II patients undergoing gynaecological day surgery were randomly allocated to induction/maintenance with propofol/isoflurane or sevoflurane/sevoflurane according to a protocol approved by the hospital ethics committee. All patients received fentanyl 1 mcg kg^{-1} Anaesthesia was induced with either propofol 2 5 mg kg^{-1} or inhalation of sevoflurane 8% in O_2 30% and N_2O 60% Propofol patients had anaesthesia maintained with isoflurane 0.6–4%. Sevoflurane patients had this agent continued at 1–4%. Patients breathed spontaneously via an LMA and a circle system (gas flow 21 min^{-1}). Induction and emergence times as well as complications were recorded peri-operatively Costs of all anaesthetic agents and disposables were calculated based on NHS list prices Data (mean values and SD) were analysed by either the Mann-Whitney "U" test or a two sample t-test with $p < 0.05$ considered significant (*)

Results: The two groups were comparable with respect to age, weight, height, ASA status, and duration of anaesthesia. Induction with sevoflurane was slower when compared to propofol (Table)

	Propofol/isoflurane	Sevoflurane
Number	20	19
Induction time (min)	1 07 (0 37)	1 43 (0 41)*
Recovery time (min)	7.11 (2 52)	6 13 (1 28)
Total cost	£11 55 (4 64)	£13 28 (5 29)

Conclusions: The cost of induction and maintenance of anaesthesia with sevoflurane in patients undergoing gynaecological day surgery is similar to propofol and isoflurane.

A.54 The ingestion of caffeine and the appearance of headache postoperatively or after an endoscopy or an x-ray procedure

A K. Zacharof, K. Petrogiannopoulos, K. Mauronaslos, M. Papadakis, J. Poulikakos. *Hellenic Red Cross Hospital, Athens, Greece*

Objective: To determine the importance of caffeine withdrawal in the complaint of headache postoperatively, or after X-ray or endoscopy procedures.

Material and Methods: We have studied 444 patients (286 men and 158 women mean age 56 ± 11 years) before and after having done a simple surgical or roentgenographic procedure or an endoscopy of upper or lower gastrointestinal tract. All patients have completed a questionnaire survey that included information of. a) on usual habit of caffeine intake, b) the caffeine use before or after the surgical, X-ray procedure or endoscopy, and c) the presence and severity of their headache accordingly.

Results: Analyzing the given answers we have found that 89% of our patients drink caffeinated beverages twice or more daily. Among regular caffeine users, 35% experienced a headache after the surgical, X-ray or endoscopy procedure compared to 11% of nonusers Among the most of heavy caffeine consumers who have abstained from beverages on the day of their procedure, 45% experienced a headache. Our final study data indicated that the use of caffeinated beverages on the previous day of the above procedures effectively prevented the headache.

Conclusions: The caffeine withdrawal is an important cause for postoperative headache, it may also cause headache in patients who are not doing surgical procedures, such as roentgenographic procedures, and endoscopy of upper and lower gastrointestinal tract

A.55 Spinal anaesthesia with hyperbaric bupivacaine 0.1% in ambulatory perineal surgery

J. Rodríguez, L. Martín, J Sobrino, M. Varela, R Cabadas, J. Blanco *POVISA Medical Center, Vigo, Spain*

Background & Goal of Study: To compare the "saddle" subarachnoid block for perineal surgery, using either 0.1% (target) or 0.5% (control) bupivacaine

Material & Methods: 48 patients scheduled for elective surgery were included The technique was performed with a 27G Whitacre needle, in the interspace L4–L5. After injection of the anesthetic solution, the patient remained in the sitting position for 5 minutes. According to the anesthetic solution, two groups were formed. A group (control), using 2 ml of 0.5% hyperbaric bupivacaine (10 mg), and B group with 4 ml 0.1% hyperbaric bupivacaine (solution obtained from mixing 4 ml plain 0.5% bupivacaine and 4 ml 5% dextrose). Both the sensitive (needle punctioning) and the motor (BROMAGE scale) blockade degree were evaluated at the beginning and end of surgery, as well as 1 hour after surgery end The patient's ability to walk 1 hour after surgery, and the time needed for discharge were also accounted Statistical analysis was performed using the t-Student for parametric data, considering a p value of less than 5%

Results and Discussion: Intraoperatory period: All patients in both groups presented an adequate sensitive blockade. 66% of the patients in the B group presented no motor blockade, whereas all patients in the control group did ($p < 0\ 05$)

Postoperatory period: The motor blockade degree was 3 in all patients of the A group, against 0.6% in the B group ($p < 0.05$) in which 84% of the patients had a 0 or 1 degree. Only a 7% of the patients in the A group were able to walk 1 hour after surgery end, compared with 67% in the B group ($p < 0\ 001$) The most frequent postoperatory complication was urinary retention requiring bladder catheter in 20% of the patients of the A group, against only 9% in group B. The time required for accomplishing requisites for hospital discharge was 287.77 ± 103 11 minutes (mean/SD) in the A group, and 126.7 ± 66 2 minutes in the control group.

Conclusions: We conclude that the use of hyperbaric 0.1% bupivacaine is an effective technique for perineal ambulatory surgery, as the degree of motor blockade is low, therefore allowing rapid mobilization and presenting a lower incidence of adverse effects. The time needed for hospital discharge is significantly lower in the B (studied) group, an important factor for patients undergoing ambulatory surgery

A.56 Comparison of rocuronium and mivacurium during outpatient surgery: propofol *vs* sevoflurane

A Robert, C. Plasman, J Massaut. *Department of Anaesthesiology, Brugmann University Hospital Brussels, Belgium*

Introduction: Short or medium acting non-depolarising muscle relaxants are preferred during outpatient surgery. Volatile agents increase the neuromuscular blocking potency of muscle relaxants The aim of this study was to compare the clinical duration of action and the recovery index between rocuronium (ROC) and mivacurium (MIV) under propofol (PRO) or sevoflurane (SEV) anaesthesia.

Methods: After IRB approval 60 consenting ASA 1–2 patients were randomly assigned to one of four groups; group 1 ROC-PRO, group 2. MIV-PRO, group 3. ROC-SEV, group 4. MIV-SEV. No premedication was used. Anaesthesia was induced with 0.2 μ/kg sufentanil and 2.5 mg/kg PRO We monitored neuromuscular function by accelerometry (TOF-Guard®), stimulating the ulnar nerve at the wrist After a stable twitch response, a single IV bolus of 0.4 mg/kg ROC in group 1 and 3 or 0 2 mg/kg MIV in group 2 and 4 was administered. Anaesthesia was maintained under N20/02 (70%/30%), with a 10 mg/kg/h PRO infusion rate (groups 1 + 2), and with sevoflurane starting with 2–2 2% (groups 3 + 4), adjusted later to a combined nitrous oxide volatile agent end-tidal concentration between 1 and 1 2 MAC For all groups, time to 90% neuromuscular bloc (nmb90), duration 25%, 75% and 90% (time to 25%, 75% and 90% recovery of T1) and the recovery index 25–75% were measured. Data were analysed using ANOVA and DUNETT T3 multiple range test with $p < 0\ 05$ considered significant

Results: The four groups were demographically comparable. The nmb90 time was shorter in groups ROC compare to groups MIV but the difference was only statistically significant for the group ROC-SEV. The duration 25%, 75% and 90% in group 3 were significantly longer than with other groups No difference was seen for the recovery index 25–75% but we found, in group 3, an important dispersion with a less predictable speed of recovery Mean ± SD; (range)

	Group 1 ROC-PRO	Group 2 MIV-PRO	Group 3 ROC-SEV	Group 4 MIV-SEV
Number (n)	15	15	15	15
nmb90 (sec)	132 ± 44	178 ± 57	108 ± 33*	181 ± 80
Duration 25% (min)	19 2 ± 4 1 (14–27)	15 2 ± 3 1 (12–21)	25 8 ± 5.3§ (18–35)	17 ± 3 7 (11–23)
Duration 75% (min)	25 9 ± 4 8 (17–32)	20 ± 4 (16–27)	35 4 ± 9 9$^{\#}$ (22–51)	22 7 ± 5 4 (15–34)
Duration 90% (min)	29 ± 6 1 (20–40)	23 5 ± 4 5 (17.5–31)	38.8 ± 11$^{\&}$ (25–57)	25 1 ± 5 9 (16–39)
Recovery 25–75 (min)	6 6 ± 2.6 (3–13)	5 ± 1 4 (3–8 5)	9 5 ± 6 4 (2 5–23 8)	5 6 ± 2 (3–11 5)

(*$p < 0\ 05$ compared to groups 2–4, §, $^{\#}$, $^{\&}$ $p < 0\ 05$ compared to groups 1–2–4)

Conclusion: The clinical duration of action after 0.4 mg/kg ROC was of 20 min. under PRO. Because of the greater potentiation of ROC by SEV and its less predictable duration, we do not recommend the use of ROC with SEV for outpatient surgery during short procedures

A.57 Effect on postoperative nausea and vomiting by antagonizing neuromuscular block

Olle Engdahl, Stefan Anskar, Susanne Oster, Carina Svedenhammar
Department of Anaesthesiology, University Hospital, Linkoping, Sweden

Background: Concerns regarding the possible side effects of neuromuscular reversal drugs have increased interest in the use of short acting non-depolarizing drugs in the outpatient setting. There is conflicting evidence regarding the emetic properties of the neostigmine reversal of these drugs and the availability of mivacurium has made spontaneous recovery after neuromuscular block possible even in short surgical procedures.

Aim of the Study: We compared the effect on postoperative nausea and vomiting (PONV) in anesthesia for day-care surgery by using, in a randomized fashion, rocuronium with neostigmine reversal and mivacurium without reversal of the neuromuscular block.

Methods: We randomized 72 female patients scheduled for lower abdominal laparoscopy under general anesthesia to receive neuromuscular blockade by either rocuronium 0 4 mg × kg^{-1} and intubation after 120 sec or mivacurium 0 2 mg × kg^{-1} and intubation after 150 sec The rocuronium patients were reversed at the end of procedure using glycopyrrolate/neostigmine 0.5/2.5 mg and the patients relaxed with mivacurium recovered spontaneously. Conditions for intubation were graded on a four-point scale, and the neuromuscular block during procedure was assessed in all patients using a TOF-Watch® and patients were not extubated until there was a T4/T1-ratio of 90% All patients received a standard pentothal-fentanyl-isoflurane anesthesia and no anti-emetic drugs were given during anesthesia The occurance of PONV in the post anesthesia care unit (PACU) was registered and all patients were followed up with a questionnaire during 24 hours postoperatively

Results: Five patients were excluded because of conversion of surgery to laparotomy or need for reversal of mivacurium Intubating conditions were graded as excellent-good in 92% in the mivacurium group and 94% in the rocuronium group. The frequency of PONV in the PACU was 26% in the rocuronium group and 36% in the mivacurium group respectively ($p > 0.25$) Data from the 24 h follow up are to date incomplete and will be presented later

Conclusions: We found no difference in intubating conditions between the two drugs There was no statistically significant difference between the groups concerning PONV in the immediate postoperative period. To summarize our data do not substantiate the avoidance of neostigmine reversal of neuromuscular block in order to decrease PONV in the postoperative period.

A.58 Patient-maintained propofol sedation for premedication in day case anaesthesia

J.A C Murdoch, G N C Kenny *University Department of Anaesthesia, Glasgow Royal Infirmary, Glasgow, UK*

Background and Goal of Study: High levels of state anxiety are commonly experienced by patients prior to surgery[1] However, standard premedication drugs can delay recovery and "home readiness" in patients undergoing day case anaesthesia[2] We aimed to assess the use of a patient maintained target-controlled infusion of propofol as a premedication prior to day case anaesthesia.

Materials and Methods: 20 adult patients undergoing day case surgical procedures under general anaesthesia were studied Anxiety was assessed using both a visual analogue scale (VAS) and the Spielberger State Trait Anxiety Inventory (STAI) Sedation was started pre-operatively with an intravenous target-controlled infusion of propofol at 1 μgml^{-1} The patient was able to increase the target concentration in increments of 0 2 μgml^{-1} by operating a control button Lockout time was 2 min and the maximum possible target concentration was 3 μgml^{-1}. If there were no demands within a set time the system decreased the target concentration in a stepwise manner Changes in anxiety scores were assessed relative to pre-sedation levels using the Wilcoxon rank sum test

Results: Mean duration of sedation was 43 1 min (range 30–72) There was a highly significant reduction in all median anxiety scores from 15 minutes after sedation was started Patients were generally lightly sedated Only 2 patients had a reduction in arterial oxygen saturation <94% and required supplementary oxygen via nasal cannulae There were no instances of airway obstruction. No clinically significant changes in heart rate or NIBP occurred Patient satisfaction, as assessed by a postoperative questionnaire, was high

Time (min)	STAI 20–80	VAS 0–100	Target [propofol] (μgml^{-1})
0	41 (33–62)	47 (33–62)	0
15	26 (23–30)*	24 (7–34)*	1 0 (0 8–1 4)
30	N/A	17 (1–24)*	1 2 (0 8–1 4)
AR	N/A	20 (5–28)*	1 2 (0 8–1 4)

Median (inter-quartile range) * $p < 0\ 0001$, AR = anaesthetic room, N/A = not assessed (n = 20) female male 14 6

Conclusions: Patient maintained propofol sedation provided a safe, rapid and highly effective anxiolytic premedication in patients undergoing day case anaesthesia

A.59 Patient controlled sedation for colonoscopy

C. Seavell, C Roseveare, J. Criswell, H Shepherd, P Patel *Royal Hampshire County Hospital, Winchester, England*

Background and Goals: Benzodiazepines and opiate boluses are commonly used for colonoscopy with the attendant risk of respiratory depression (1) Patient controlled sedation (PCS) using propofol and alfentanil, allows titration of dosage to individual needs (2) We wished to compare these two methods for colonoscopy

Materials and Methods: 66 ASA 1 or 2 day case patients were enrolled. These were randomly allocated to either pethidine 50 mg and diazepam 10–20 mg bolus, dose decided by the endoscopist, (Group 1) or PCS (Group 2) using a Graseby 3300. The infusion contained propofol 10 mg/ml and alfentanil 25 μg/ml A 0.5 ml bolus could be self administered every 7 secs. 4 boluses were delivered early in the procedure then as needed All patient received 2 L/min O_2 were monitored and their sedation assessed. Number completion tests were timed pre and post procedure and patients followed up with a phone call 2 days later Mann-Whitney U tests, X^2 and t-tests were used as appropriate, $p < 0\ 05$ was taken as significant.

Results and Discussion: Group 1 received a median of 15 mg diazepam with pethidine 50 mg In group 2 there was a strong correlation between duration of procedure and dose ($r = 0\ 61$, $p < 0\ 0001$) Median (range) dose of PCS was 11 (2.5–22) mls and median (IQR) infusion rate was 6.25 (4 4–8.6) mg/kg/hr Duration of procedure was unaffected by the type of sedation PCS provided less sedation ($p = 0.0001$), less analgesia ($p = 0.004$) and recovery time was shorter with PCS, median (range) 10 (10–40) mins v 40 (10–240) mins in group 1 ($p = 0\ 0001$) Maximum fall in systolic BP was greater in group 1 Verbal contact was lost with 15 v 2 patients in group 1 and 2. 14 patients in group 1 had after effects disrupting lifestyle v. 3 in PCS group.

Conclusions: PCS provided lighter sedation, faster recovery times and less post procedure side effects, caused less fall in BP with no change in procedure duration or success rate but provided less analgesia than standard sedation

A.60 Accuracy of waking time estimation after sedation by a computerized target-controlled infusion system

E. Knolle, R. Fricker, S Stoklas, H.G Kress. *Dept.(B) of Anaesthesiology & General Intensive Care, University of Vienna, A-1090 Vienna, Austria*

Background & Goal of Study: Some computerized target-controlled infusion (TCI) systems calculate the time between stop of infusion and waking of the patient. The estimation can be influenced by changing the preset threshold drug level for awaking Using target concentrations ≥2 5 μg ml^{-1} for sedation in oral surgery, we wanted to find out whether a threshold of 2.4 μg ml^{-1} provides better estimates of waking time compared to a preset level of 1 2 μg ml^{-1}

Materials & Methods: For oral surgery 30 adults were sedated using propofol administered by TCI (Diprifusor®, Zeneca)[1] The threshold value for the estimation of waking time was adjusted to 1 2 μg ml^{-1} (group I, n = 15) or 2 4 μg ml^{-1} (group II, n = 15) The estimated waking time at the end of infusion and the time the patient actually needed to open his eyes and tell his name were registered The differences were verified with the Wilcoxon matched-pairs test

Results & Discussion: The mean actual waking time in seconds was 179 s ± 108 s (Mean ± SD). The difference between estimated and actual waking times was significant in group I ($p < 0\ 01$), but not in group II

	Total of propofol (mg)	Duration of TCI (s) (s)	Waking time (s)		Difference (s)
			estimated	actual	
I	614 1 ± 232 6	4068 ± 1815	1041 ± 589	176 ± 110	865 ± 578
II	713 7 ± 327 9	4640 ± 1957	131 ± 116	182 ± 110	108 ± 120

Mean ± SD

Conclusion: Using a propofol Diprifusor® system for sedation in oral surgery average waking times of about 3 minutes are usually to be expected. The estimation of the waking time should be based on a threshold value of 2.4 $\mu g \cdot ml^{-1}$ rather than on 1.2 $\mu g \cdot ml^{-1}$. Based on a threshold value of 2.4 $\mu g \cdot ml^{-1}$ waking times considerably different from 3 minutes may result from an inappropriate level of sedation.

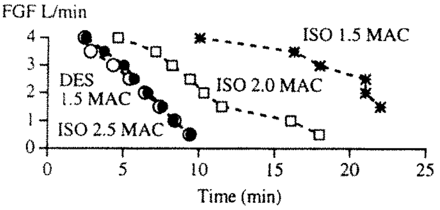
A.61 Inspired concentrations of desflurane and isoflurane required for equivalent rates of inhaled induction

W. Stevens, A. Bengtsson. *Department of Anesthesiology, Oregon Health Sciences University, Portland, Oregon, USA*

Background and Goal of Study: A potential advantage of inhaled anesthetics of low blood solubility is they allow change from high to low flow fresh gas flows (FGF) early in anesthesia while maintaining good control of the end-tidal anesthetic concentration (F_{et}). The aim was to determine how high the inspired concentration (F_i) ISO has to be to allow as rapid induction and achievement of low FGF as with low F_i DES.

Material and Methods: After IRB approval, we studied 28 ASA I or II patients, divided equally between four groups defined by the following delivered anesthetic concentrations (F_d): DES 1.5 MAC and ISO 1.5, 2.0 and 2.5 MAC. After tracheal intubation and with $P_{et}CO_2$ controlled between 35–40 mmHg, inhaled induction was done with FGF of 4.0 L/min O_2 and assigned anesthetic. When F_{et} DES or ISO reached 1.1 MAC, FGF was decreased by 0.5 L/min to 3.5 L/min while maintaining constant F_d DES or ISO. Successive 0.5 L/min decreases of FGF were made each time F_{et}DES or ISO reached 1.1 MAC. Median values and ranges are given.

Results and Discussion: Fet = 1.1 MAC was reached in 3.8 min (2–5.5) with DES 1.5 MAC, 2.4 min (1.5–3.0) with ISO 2.5 MAC, 4.6 min (2.0–7.5) with ISO 2.0 MAC and 18 min (5–38) with ISO 1.5 MAC. FGF could be decreased to low flow within 10 minutes without sag in F_{et} DES. Longer times at each FGF were required with ISO 1.5 MAC to allow F_{et} to rise to the target level before making the next decrease in FGF compared to with DES 1.5 MAC or ISO 2.5 MAC ($p < 0.05$) (Figure).



Conclusion: The times to achieve an anesthetizing F_{et} of DES or ISO were similar to reported values obtained under similar conditions. Only modest F_d overpressure leads to rapid induction and sustained F_{et} as FGF is decreased with DES whereas longer periods of higher F_d or FGF would be needed with ISO for rapid induction and stable F_{et}. ISO 2.5 MAC almost exactly resembled DES 1.5 MAC.

A.62 Cost minimization comparison of sevoflurane compared with propofol and isoflurane for the induction and maintenance of anaesthesia in day case surgery

J.M. Murray[1], C.W. Renfrew, T.B. Lytle[2], S.J. Coles[2]. [1]*Royal Victoria Hospital, Belfast;* [2]*Abbott Laboratories, Maidenhead, Berkshire SL6 4XE,*

Background and Goal of the Study: Propofol and isoflurane are commonly used agents for day case anaesthesia. Recent studies comparing isoflurane with sevoflurane in out patients indicated improved recovery characteristics can be obtained in those patients who had maintenance of anaesthesia with sevoflurane [1, 2]. We have compared the costs of sevoflurane and propofol/isoflurane based induction and maintenance techniques and related these to patient morbidity, acceptability, anaesthesia and recovery times in a multi-centre hospital study.

Methods: Following local ethics committee and written consent, 186 patients (ASA I–II) scheduled for day case surgery in 7 NHS hospitals were randomly allocated to induction and maintenance with propofol/isoflurane (P/I) or sevoflurane/sevoflurane (S/S). Anaesthesia was induced with 1 mcg/kg fentanyl followed by either propofol (2.5 mg/kg iv) preceded by 1–2 ml of 1–2% lignocaine iv or by inhalation of sevoflurane 8% using a single vital capacity breath technique. Induction was timed to the loss of eyelash reflex. Patients in the propofol group had anaesthesia maintained with isoflurane 0.2–5.0% and those in the sevoflurane group continued with sevoflurane 0.5–8%. Both anaesthetic agents were administered during maintenance of anaesthesia using a laryngeal mask airway (LMA) with a rebreathing system at a flow rate of 1–2 L/min in 30–50% O_2 and 50–70% N_2O. Induction and emergence times as well as complications were recorded. The costs of isoflurane and sevoflurane, and all other anaesthetic agents and disposables were calculated from the NHS list price Data (mean, SD) were analysed by either the Mann Whitney "U" test or a two sample t-test with $p < 0.05$ considered significant (*).

Results: The two groups were similar with respect to patient characteristics, PONV and duration of anaesthesia. Induction with sevoflurane was slower compared with propofol, but recovery was faster with sevoflurane (table). The mean costs of induction and maintenance of day case anaesthesia in both groups were £10.63 (P/I) and £11.89 (S/S).

Table

Group	P/I	S/S
Cost (£)	10.63 (3.96)	11.89 (3.62)
Patients (n)	92	94
Induction time (min)	1.10 ± 0.53	1.43 ± 0.74*
Anaesthesia time (min)	21.7 ± 10.8	21.9 ± 11.9
Recovery time (min)	8.26 ± 4.41	6.95 ± 2.99*
Vol of iso used (mL)	7.0 ± 2.67	–
Vol of sevo used (mL)	–	18.19 ± 3.63

Conclusion: The cost of induction and maintenance of anaesthesia with sevoflurane in patients undergoing day case surgery is similar to propofol and isoflurane.

A.63 Evaluation of respiratory problems during prolonged usage of cuffed oropharyngeal airways. Comparison with laryngeal mask airway

G.S. Voyagis, V. Dimitriou, A. Tragou, N. Charisi, V. Georgakopoulou. *Departments of Anaesthesia, Sotiria and G. Gennimatas Hospitals, Athens, Greece*

Aim of the Study: To evaluate objective differences in airway parameters and respiratory side effects between COPA and LMA in patients undergoing prolonged procedures.

Methods: 140 patients, ASA I–III, aged 64 ± 11 years, scheduled for limbs or surface prolonged procedures (>1 h) were randomly assigned to one of two airway management groups (COPA n = 72, LMA, n = 68). Patients with anticipated airway difficulties and those at high risk of regurgitation were excluded. The selection of size and the insertion technique for both airways used were carried out according to the inventors' guidelines. All patients received i.v. propofol 2.0–2.5 mg/kg and fentanyl 1 μg/kg for induction; N_2O 66% in O_2 and sevoflurane 1–4% for maintenance. Ventilation was manually assisted until a regular breathing pattern was established and supplemental doses of fentanyl 25 μg were administered when required. The presence of difficulties in airway insertion, signs of airway obstruction, laryngospasm, regurgitation, desaturation persisting >30 s. (SpO_2 90–94%: +, <90%: ++) and hypercarbia persisting >3 min ($ETCO_2$ 45–52.5 mmHg: +, >52.5 mmHg: ++) were recorded.

Results: There was no difference between the groups in terms of demographic data and length of surgical procedure (COPA: 89 ± 28 min, range: 70–270 min; LMA: 95 ± 37 min, range: 60–410 min). No patient required intensive care management or any additional treatment postoperatively. All results in the table are expressed as probability (%).

Problem	Group COPA		Group LMA		P**
	+	++	+	++	
– Difficult insertion	2.8[a]	0	7.4[a]	0	0.3
	2.8[b]	0	4.4[b]	0	
– Compromised airway	16.7[c]	2.8*[c]	4.4[c]	0	0.08
			2.9[d]		
– Desaturation	5.5	2.8	4.4	2.9	1.0
– Hyrercarbia	38.9	4.1	42.6	1.5	0.7

+: moderate, ++: severe, [a]coughing or gagging, [b]multiple attempts, [c]airway obstruction, [d]laryngospasm, *need for LMA insertion, **chi-square test.

Conclusion: The prolonged use of COPA appears to be an acceptable alternative to LMA in spontaneously breathing patients under general anaesthesia. The incidence of respiratory problems did not differ in both groups.

A.64 Choice of cuff inflation medium during nitrous oxide anaesthesia

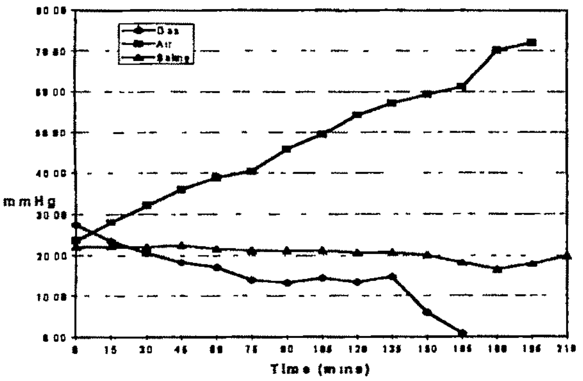
V. Mitchell, T Adams, I Calder *The National Hospital for Neurology & Neurosurgery, London, UK*

Background & Goal of Study: An increase in tracheal tube cuff pressure is seen during anaesthesia incorporating nitrous oxide if air is used to inflate the cuff [1] It has been suggested that this increase in pressure might cause morbidity and could be avoided by filling the cuff with anaesthetic gas mixture or saline [2, 3] We undertook this study because we had noticed that cuffs inflated with gas mixture sometimes deflated.

Materials & Methods: 30 patients undergoing elective neurosurgical procedures were randomly assigned to one of three groups and following intravenous induction of anaesthesia and neuromuscular paralysis, the trachea was intubated with a reinforced tracheal tube The cuff of the tracheal tube was inflated with either air, sterile 0.9% saline or anaesthetic gas mixture (66% N_2O/33%O_2), the cuff pressure was adjusted to between 18 and 30 mmHg and recorded at 15 minute intervals for the duration of anaesthesia Patients were interviewed the day after the operation to determine the incidence of hoarseness and sore throat Multiple regression analysis was used to test the hypothesis that there is no change in cuff pressure over time

Results & Discussion: Large increases in cuff pressure were seen in the air group, but no morbidity resulted The intra-cuff pressure decreased in the gas mix group and leaks occurred in some patients The pressure remained stable in the saline group. The null hypothesis was rejected in both the gas and air groups

Changes in Tracheal Cuff Pressure
(mean values in each group in mmHg)



Conclusions: The use of gas mix results in deflation of the cuff and cannot be recommended because of the risks of hypoventilation and aspiration Saline provides stable cuff pressures during nitrous oxide anaesthesia but initial adjustment of cuff volume is often required Cuff pressure increases markedly when air is used for cuff inflation, but we found no evidence of any consequent morbidity. Air is therefore the agent of choice in patients at risk of regurgitation

A.65 Attenuation of vasomotor responses to tracheal intubation. Comparison of tramadol, pethidine, nalbuphine and placebo

A A. van den Berg, E. Halliday *Anaesthesia Dept, Military Hospital, Riyadh, Saudi Arabia*

Introduction: Tramadol, an opioid acting primarily at μ-receptors and on the monoaminergic modulating systems, is not habituating or respiratory depressant, but has an efficacy comparable to pethidine and nalbuphine [1, 2]. This study was undertaken to compare the relative abilities of equipotent doses of tramadol, pethidine and nalbuphine to attenuate the vasomotor responses to tracheal intubation

Methods: With informed consent and Ethical Committee approval 280 patients were studied. All received temazepam 0.5 mg kg^{-1} as premedication and randomly received tramadol 3.0 mg kg^{-1}, pethidine 1.5 mg kg^{-1}, nalbuphine 0.3 mg kg^{-1} or isotonic saline 0.02 ml kg^{-1} intravenously (I.V) prior to induction of anaesthesia with thiopentone 4.0 mg kg^{-1}, atracurium 0.6 mg kg^{-1}. Recordings of heart rate (HR), systolic, diastolic and mean arterial pressures (SAP, DAP and MAP) were made prior to injection of test drug, 60 seconds after induction of anaesthesia and at 1, 3, 5, and 7 minutes after laryngoscopy and tracheal intubation Data were analysed by ANOVA and Students' 't' tests, with $p < 0.05$ significant

Results:

		Heart rate (bpm)				SAP (mm Hg)			
		Pre-ind		Peak post-int		Pre-ind		Peak post-int	
	N	M	SD	M	SD	M	SD	M	SD
Sal	69	90	22	117	21	121	20	146	30
Tram	70	93	22	120	23	118	16	142	25
Peth	69	91	22	123	23	119	19	135	28
Nalb	72	89	22	109	18	117	17	130	26

N = patient number, Data given as M (mean) SD

Increases in HR and SAP were maximal 1 minute after intubation, and were significant in each group ($p < 0.001$ each drug and each comparison versus baseline) Tachycardia after nalbuphine was less than after placebo ($p < 0.02$), tramadol ($p < 0.005$) and pethidine ($p < 0.001$) Hypertension after nalbuphine was less than with placebo ($p < 0.001$) and tramadol ($p < 0.01$), but similar to pethidine

Conclusion: Attenuation of the cardiovascular responses to tracheal intubation tests the efficacy and speed of onset of an analgesic Here, tramadol proved indistinguishable from saline (placebo), pethidine reduced the hypertension but induced most tachycardia (reflecting its atropine-like effect), while nalbuphine most effectively reduced all responses to intubation. Since tramadol, pethidine, morphine and nalbuphine have similar analgesic efficacy [1, 2], tramadols inefficacy in this study may reflect a slow onset and suggests it may be better given some 5 minutes prior to intubation [3]

A.66 Airway management and the incidence of sore throat

E.V. Addy, A. Kapila, C Verghese. *Department of Anaesthetics, Royal Berks Hospital Reading, UK*

Background and Goals of Study: Since the introduction of the laryngeal mask airway (LMA) in 1983, minor morbidity following its use have been documented but there is a wide variation in the incidence of reported problems[1, 2] This prospective audit was undertaken firstly to establish the pattern of usage of airway devices in elective surgery by consultant anaesthetists and secondly to establish the incidence of sore throat following the use of these devices.

Materials and Methods: 968 consecutive fasted adult patients presenting for general surgical, gynaecological, orthopaedic and genitourinary procedures under general anaesthesia were audited The age, sex, surgical procedure, duration of surgery, airway device used (LMA, tracheal tube (TT), or face mask (FM)) and the use of lubricant were recorded Patients were asked whether they had a sore throat immediately prior to discharge to the ward (early) and again before discharge from hospital (late) Data was analysed using the statistics software package SAS version 6.08

Results and Discussion: Management of the airway was with the LMA in 791 patients (81.7%), the TT in 71 patients (7.3%) and the FM in 106 patients (11%). Logistic regression models fitted to the proportion of patients having a sore throat in the recovery room (early) showed a significant difference between the airway device used in the incidence of sore throat ($p < 0.0001$). The early incidence of sore throat was 27.0%, 14.3% and 1.5% when the airway device used was a TT, LMA or FM respectively. The corresponding late incidence of sore throat was 5.8%, 3.1% and 0%. Age, duration of surgery or lubricant use had no effect on the incidence of sore throat. The overall incidence of sore throat was higher in women (11.4%) than in men (7.5%)

Conclusions: In elective surgery, the 1st choice for airway management with this group of consultants is the LMA, the TT only being used when there is a specific indication. A significant difference was found in the incidence of sore throat between the 3 airway devices.

Swallowing after thyroidectomy in patients over 70 years of age without recurrent laryngeal nerve damage

L. Lacoste[1], J.C. Ferrié[2], P. Ingrand[3], F. Lebrun[1], J. Fusciardi[1].
[1]Departments of Anaesthesiology; [2]Radiology; [3]Biostatistics, University Hospital of Poitiers, 86021 Poitiers, France

The aim of this prospective study is to evaluate swallowing difficulties after thyroidectomy in patients over 70 years of age having no recurrent laryngeal nerve (RLN) damage.

Patients and Methods: Patients over 70 years of age (n = 123) who had undergone thyroidectomy under general anaesthesia were divided into two successive groups. In group I (n = 50), patients had a laryngeal examination and a chest x-ray after ingestion of 10 cc of a contrast medium (Hytrast®) before and after surgery at day (D0) then day 2 (D2). Group II patients (n = 73) underwent only the laryngeal examination at D0 and D2. Tracheobronchial aspirations (TBA) were evaluated using nurses' (N) and patients' (P) daily reports. Three supplementary evaluations were performed in group I: ENT evaluation (D2), clinical and x-ray reports after Hytrast® ingestion. The consequences of TBA were determined using chest x-rays and thermal curves.

Results: 10 patients out of 123 (76 ± 5 yrs) having RLN damage were excluded from the analysis. The table shows patients with TBA on N and P reports. In GI, the ENT evaluation showed no TBA, Hytrast® ingestion x-rays showed one clinical and one radiological TBA. X-ray analysis showed ventilation difficulties in one patient with radiological TBA as well as in 6 other without signs of TBA, primarily flat atelectasias. Thermal curve results revealed temperatures above 37.7°C in 1 patient at D0, 11 at D1, 7 at D2 and 3 at D3.

Table: Thyroidectomies: patients over 70 yrs without RLN damage and with tracheobronchial aspiration (TBA)

	N0	P0	N1	P1	N2	P2	N3	P3
TBA (n)	0	4	1	2	0	2	0	2
Patient (n)	91	74	88	79	66	75	42	75
TBA (%)	0	5.4	1.1	2.5	0	2.7	0	1.3

N: nurses reports P: patient reports, 0 = D0; 1 = D1; 2 = D2; 3 = D3

Conclusion: After thyroidectomy, approximately 5% of patients over the age of 70 without RLN damage had TBA's. These TBA disappeared in more than half of these patients at day 3.

A.68

Swallowing after thyroidectomy: impact of recurrent laryngeal nerve damage in patients less than 70 years of age

L. Lacoste[1], J.C. Ferrié[2], P. Ingrand[3], M.S. Lehuédé[1], J. Fusciardi[1].
[1]Departments of Anaesthesiology; [2]Radiology; [3]Biostatistics, University Hospital of Poitiers, 86021 Poitiers, France

The aim of this prospective study is to evaluate swallowing difficulties after thyroidectomy.

Patients and Methods: Patients less than 70 years of age were divided into two groups according to the results of a laryngeal examination performed in the recovery room: GI (n = 100), patients with RLN damage; GII (n = 100), patients without RLN damage, each chosen at random. Each patient underwent a laryngeal exam and a chest x-ray after ingestion of 10 cc of a contrast medium (Hytrast®) prior to surgery and after surgery on day 0 (D0) then day 2 (D2). Tracheobronchial aspirations (TBA) were rated using five different evaluations: nurses' (N) and patients' (P) daily reports, ENT evaluations (D2), clinical reports and x-rays after Hytrast® ingestion. The consequences of TBA were evaluated using x-rays and thermal curves. Statistical analysis included Fischer (2-tail) exact and Mann Whitney tests ($p < 0.05$).

Results: ASA physical status, anaesthesia, surgical technique, pain and side effects were comparable in the two groups. In GII, 3 patients were excluded because of ENT abnormalities detected on D2. The table shows the patients suffering from TBA for N and P. In GI, 10 patients TBA were shown upon ENT evaluation, for the clinical report and x-ray after Hytrast® 3 patients in each group and 1 patient in GI. X-ray analysis showed 14 and 15 patients with ventilation difficulties in GI and GII respectively, primarily flat atelectasias. There was no significant difference between the number of patients with >37.7°C.

Table: Thyroidectomies: patients <70 yrs suffering from tracheobronchial aspirations

	N0	P0	N1	P1	N2	P2	N3	P3
GI (n)	23^{+}	20^{+}	20^{+}	18^{+}	12^{+}	9*	6*	4
GII (n)	1	4	1	1	1	0	0	0

GI: RLN damage (n = 100) N: nurses reports, GII: without RLN damage (n = 97) P: patient reports, 0 = D0; 1 = D1 2 = D2 3 = D3, $^{+}$: $p < 0.01$, *: $p < 0.05$

Conclusion: After thyroid surgery, RLN damage is associated with 20% TBA ($p < 0.01$). These TBA are rarely shown by Hytrast®. They disappear in 50% and 75% of patients at D2 and D3 respectively. In this series, the radiographic and thermal consequences are not significant.

A.69

Effects of endotracheal intubation and laryngeal mask airway insertion on the risk of myocardial ischaemia in cardiac patients

B. Ay, Z. Eti, A.S. Fak, T. Umuroğlu, F.Y. Göğüş. *Marmara University Faculty of Medicine, Anaesthesiology and Reanimation Department İstanbul, Turkey*

Background & Goal of Study: The aim of this sudy was to compare the effects of endotracheal intubation (ET) and insertion of laryngeal mask airway (LMA) to the risk of myocardial ischemia in patients with coronary artery disease (CAD) during non-cardiac surgery.

Materials & Methods: After Faculty Ethics Committee approval and patients' written consent 30 patients, 60–80 years old, ASA III–IV scheduled for elective peripheric surgery were included in the study. Patients were evaluated by Goldman and Detsky Cardiac Risk Index and according to the results of echocardiography before surgery then were assigned into two groups (n = 15) equally according to the risk factors. Anaesthesia was induced with 0.2 mg/kg etomidate, 15 μg/kg alfentanil, 0.1 mg/kg vecuronium bromide i.v. in all patients. In the I. group the patients were intubated, in the II. group LMA was inserted for maintenance of airway. Mean arterial pressure (MAP), heart rate (HR), rate-pressure product (RPP) and ST segment changes with 5 lead ECG were recorded before and after induction, during and after 1, 3, 5 minutes of airway manipulation. 12 Lead ECG and CPK, CPKMB levels were recorded preoperatively and 6., 24. hours postoperatively. The results were compared statistically with ANOVA, Tukey Kramer, Student Keuls and Fischer's Exact tests ($p < 0.05$).

Results & Discussion: MAP, HR and RPP increased significantly 1 minute after intubation in the I. group, there was no difference in MAP and RPP and a significant decrease in HR at all time intervals in the II. group. ST segment changes were recorded 15 times in 6 patients in the I. group and 4 times in 3 patients in LMA group ($p < 0.05$). CPKMB value was greater than 25 IU/ml in 3 patients who had ST segment changes in the I. group.

Conclusion: Unless contraindicated; airway maintenance by LMA causing less hemodynamic and ST segment changes compared to ET should be preferred in patients with CAD in order to protect myocardial perfusion.

A.70

Use of a cuffed oropharyngeal airway to assist fibreoptic laryngoscopy and tracheal intubation using the Portex bougie

M. Hawkins, E. O'Sullivan, P. Charters. *Aintree Hospitals, Liverpool, UK*

Background: The Cuffed Oro-Pharyngeal Airway (COPA) is a new device based on a Guedel airway, but with a pharyngeal cuff and a standard 15 mm connector. Its internal dimensions allow a fibreoptic laryngoscope (FOL) to pass through it. A new bougie is now marketed. It has a Coudé tip, is hollow, disposable and cheaper to produce than the gum elastic bougie. It also fits through the COPA, so may be of use with a FOL when conventional methods for tracheal intubation prove difficult.

Goal: To evaluate the COPA in assisting fibreoptic tracheal intubation with the bougie.

Methods: 20 adult patients, ASA 1–2, were recruited. Those at risk of reflux or difficulty with intubation were excluded. They were anaesthetised and paralysed. After 3 minutes, direct laryngoscopy was performed. A COPA was then inserted and manual ventilatory support continued. The FOL was passed through the COPA via a sealed angle piece. The laryngeal view was scored thus: 4, only cords seen; 3, cords plus posterior epiglottis; 2, cords plus anterior epiglottis; 1, cords not seen (1). Manipulations needed to improve the view were noted. The bougie was passed through the COPA and attempts made to advance it into the trachea. If successful, the FOL and COPA were removed and an endotracheal tube (ETT) railroaded over the bougie. The time from FOL insertion to intubation of the trachea was recorded. 2 anaesthetists performed all manoeuvres for 10 cases each.

Results and Discussion: Ventilation was satisfactory in all cases, needing increased fresh gas flow in 4 to overcome a leak. In 12/20 there was some view of the larynx after insertion of the COPA (a score of 2, 3 or 4) increasing to 19 after manipulations which included; jaw lift, downward rotation of COPA, slight pulling out of COPA. Intubation was easy in 11/20 with 5 causing slight difficulty and 4 being very difficult. The Coudé tip impinging on the anterior larynx caused most difficulties. This was overcome by rotating the bougie in 5 cases and removing it to use its opposite end in 4. The mean times for intubation for the anaesthetists were 124 and 127 seconds (no significant difference). There was a tendency toward a learning curve but no plateau was reached. This contrasts with a study using the Aintree catheter (a ventilation/exchange catheter) on the FOL (2) instead of a bougie. This showed faster intubation times; less difficulty with intubation and no learning curve. Overall, the COPA is easy to use and one can intubate through it though a bougie is not the ideal tool to use

A.71 Optimum cuff inflation in cuffed oropharyngeal airway

V Dimitriou, G S. Voyagis. *Departments of Anaesthesia, G Gennimatas and Sotiria Hospitals, Athens, Greece*

Background: COPA is a new airway recommended for short-term procedures involving spontaneously breathing patients with little risk of aspiration. When the COPA is inserted it is necessary to produce a seal so that adequate minute volumes may be achieved, for the period that the patient is manually ventilated, to the time of spontaneous ventilation restoration. Previous experience with cuffed airways has shown that overinflation produces a marked increase in pressure applied to the mucosal wall resulting in mucosal ischaemia (1). Although certain volumes of air have been suggested as appropriate for the different COPA sizes, the justification for these has not been established with respect to the pressures applied to the pharyngeal mucosa. This study investigates the optimum cuff inflation in order to achieve a seal for adequate minute ventilation.

Materials and Methods: In the study were included 22 fasted patients (ASA I–II). Anaesthesia was induced with propofol 2–2.5 mg/kg and fentanyl 1 $\mu g/kg$ and maintained with N_2O 66% in O_2 and sevoflurane 2%. After induction the COPA (sizes 9, 10) was inserted and the cuff inflated with air 30 ml and 35 ml respectively (Vcuff initial), according to manufacturer instructions and the cuff pressure measured by a connection to a standard pressure transducer (Pcuff initial). Then the patient was mannually ventilated and checked for a leak sound from the cuff. The cuff was then deflated or inflated appropriately in order to achieve a seal at a peak airway pressure of 17 cmH_2O. The final cuff volumes and cuff pressures as well as the tidal volumes (V_T) achieved were recorded.

Results: Cuff was deflated in 14 patients (63.6%), inflated in 6 (27.3%) while no adjustment was needed in 2 (9.1%). Our results are summarized in the table:

	V cuff (ml)	Pcuff (cmH_2O)	V_T (ml)
Initial	32 ± 3	100 ± 29	882 ± 206
Final	29 ± 6	71 ± 39	837 ± 169
P-value	0.02	0.008	0.4 (NS)

Conclusion: Our results demonstrate that the manufacturer's suggested cuff volumes do not necessarily fit to all patients and so there is a need of further titration in order to achieve a seal that is a prerequisite for a safe and effective ventilation

A.72 Clinical evaluation of the cuffed oropharyngeal airway during positive-pressure ventilation

B Haberland, H. Kuhne, H. Guggenberger, K Unertl *Department of Anesthesiology, Eberhard-Karls-Universitat Tubingen, Germany*

Background: The utility of the Cuffed Oropharyngeal Airway (COPA) during positive-pressure ventilation has yet to be determined. The aim of this study was to evaluate the utility of the COPA during positive-pressure ventilation and to assess whether significant leaks occurred and if leaks were associated with gastroesophageal insufflation.

Methods: 75 patients (ASA I–III, 60 male, 15 female) undergoing elective urologic surgery received a standard anesthetic technique of alfentanil 12.7 ± 3.7 $\mu g/kg$ followed by propofol 2.7 ± 0.5 mg/kg for induction and O_2/N_2O/propofol for maintenance. After induction of anesthesia and insertion of the COPA controlled ventilation was used with four different peak pressure settings (10, 15, 20 and 25 cmH_2O) in each patient. Data collected included the ease of insertion and quality of "hands-free" anesthesia, inspiratory and expiratory volumes, gastroesophageal insufflation and leak at the neck

Results: Average duration of COPA ventilation was 54 min (range 20–150 min.). Insertion of the device was easy in 73 cases (98%). In 51 patients (68%) additional manipulations (e.g. changing of COPA size, increasing cuff volume, hyperextension or turning of the head) were necessary to reach satisfactory ventilation. The overall rating of the COPA was noted as excellent in 42 cases (56%), good in 17 cases (23%), fair in 11 cases (15%) and poor in 5 cases (7%). In 2 patients (3%) endotracheal intubation became necessary because of inadequate airway seal and patient bucking. No severe side effects like laryngospasm, regurgitation, aspiration or teeth damage were registered. One patient developed a sore throat. Blood tinged secretion was noted in 3 cases.

Tidal volumes (mean ± SD) at 10, 15, 20 and 25 cmH_2O were 510 ± 158 ml, 726 ± 201 ml, 863 ± 226 ml and 996 ± 235 ml, respectively. Leak fractions at these pressure settings were 0.09 ± 0.08, 0.12 ± 0.12, 0.16 ± 0.14 and 0.16 ± 0.12, respectively. The frequency of gastric insufflation ranged from 1.3% at a ventilation pressure of 10 cmH_2O to 12.5% at 25 cmH_2O. The mean peak pressure to reach a tidal volume of 10 ml/kg was 18.5 cmH_2O (range 11–30 cmH_2O). Gastric insufflation occurred in 4%

Conclusion: The COPA provides adequate positive-pressure ventilation during general anesthesia for interventions of limited duration. The handling of the COPA is easy and the device is well tolerated. It is contra-indicated in patients with increased risk for aspiration

As gastroesophagal insufflation of air becomes a problem in the presence of increased ventilation pressures, airway resistance and compliance must be satisfactory.

A.73 A comparison of the laryngeal mask airway and the cuffed oropharyngeal airway for manual positive pressure ventilation

G.S. Voyagis, V. Dimitriou *Departments of Anaesthesiology, Sotiria and G. Gennimatas Hospitals, Athens, Greece*

Background and Goal of Study: The internal diameter and length of the laryngeal mask airway (LMA) are optimum as regards the airway resistance, but the flexible bars in the bowl of the LMA may impede gas flow (1). The cuffed oropharyngeal airway (COPA) is a new form of airway which performs as a non-invasive aid in airway management recommended for short-term procedures involving spontaneously breathing patients with little risk of aspiration. In this comparative study we investigated the possible differences between the most commonly used LMA sizes (3 and 4) and COPA (length 10 cm) concerning the ventilatory variables during manual positive pressure ventilation (MPPV)

Methods: After institutional approval and written informed consent 30 ASA I–II adult patients scheduled for procedures under general anaesthesia with spontaneous ventilation underwent a double comparative trial. Patients with anticipated airway difficulties and those at high risk of regurgitation were excluded. General anaesthesia was induced with midazolam 0.04 mg/kg, fentanyl 2 $\mu g/kg$ and propofol 2.5 mg/kg and was maintained with sevoflurane 1–4% and N_2O 66% in O_2. All patients initially underwent gentle MPPV with COPA for three minutes. The maximum values of tidal volume (V_T) and the peak inspiratory pressure in which air-leak occurred (Paw-leak) were recorded. Afterwards the COPA was replaced by LMA and the same ventilatory variables were recorded. All measurements were made during the post-induction apnoeic period with the patient in supine position and before skin incision

Results: Are summarized in the table

	COPA	LMA	P-value
Paw-leak (cm H2O)	18.4 ± 3.8	26.3 ± 4.7	<0.0001
V_T (ml/kg)	12.2 ± 3.0	13.8 ± 4.3	0.1

Conclusion: LMA provides a better airway seal that contributes in achievement of higher values of Paw-leak, although MPPV through the COPA seems to offer similar VTs. However, our measurements and results apparently concern a healthy surgical population

A.74 Comparison of cuffed oropharyngeal airway and laryngeal mask airway

L. Versichelen, M Struys, G. Rolly *Dep of Anaesthesia, University Hospital, Gent, Belgium*

Background and Goal of the Study: The COPA[1] is a modified Guedel airway device with a specially designed cuff at its distal end and a 15 mm connector at its proximal end. It was the aim of the study to compare the COPA with the LMA[2] on 1) haemodynamic (blood pressure and heart rate) and cerebral responses (changes in bispectral index) at insertion of the device, 2) quality of insertion and maintenance of a free airway, 3) need for additional manipulations, 4) side effects and 5) complications.

Methods and Material: After institutional approval and patient consent, 35 female patients (18 COPA and 17 LMA) scheduled for short ambulatory gynaecological procedures were included. Patients were premedicated with midazolam (0.03 mg/kg 5 min and alfentanil 0.5 mg 2 min before induction. Anaesthesia was induced and maintained with a propofol target controlled infusion device (Stanpump®). The COPA/LMA was inserted 4 min after induction. Spontaneous breathing was aimed at. Data are presented as mean ± SD. Data were analysed using ANOVA and t-test for paired data.

Results and Discussion: Anthropometric data were similar in both groups. At insertion, more pronounced increase in diastolic blood pressure

P25792

was found in LMA ($p < 0.05$). Increase in systolic blood pressure and heart rate was similar in both groups. Cerebral response, defined as bispectral index increase, was for LMA 12 ± 10 and for COPA 15 ± 10 (NS). Quality of insertion was easy For the LMA 100% at the first attempt and for the COPA 89% at first and 11% at second attempt No failure was observed. Airway support during insertion and maintenance was better in the LMA group, more additional manipulations (jaw thrust, hyperextension or both) were necessary in the COPA group. No additional manipulations were necessary in LMA. Quality of inflation and deflation of the cuff and removal of the device was nearly identical in both groups. Side effects were few in both groups (coughing 2/17 LMA vs. 1/18 COPA; bucking 2/17 LMA vs. 0/18 COPA; blood on the cuff (3/17) and lip trauma (1/17) in LMA vs blood on the cuff (3/18) COPA). No laryngospasm nor regurgitation were seen in both groups.

Conclusions: No differences in haemodynamic and cerebral stimulation was observed during the insertion of both devices Compared to the LMA, the insertion of the COPA is easier but needs more additional manipulations to obtain adequate airway support. The COPA is a single use device with an excellent overall quality for airway support in sponteneously breathing patients.

A.75 Use of esmolol to attenuate haemodynamic responses to tracheal intubation, eye bandaging and tracheal extubation during cataract surgery

A A van den Berg. *Department of Anaesthesia, King Khaled Eye Specialist Hospital, Riyadh, Saudi Arabia*

Introduction: Esmolol attenuates haemodynamic responses to intubation and extubation [1, 2]. At the end of cataract surgery, gentamycin injection and eye bandaging have chronotropic and inotropic effects, augmented by reversal of neuromuscular blockade (RNB) and extubation [3] We investigated the effects of 1) esmolol 4 0 $mg.kg^{-1}$ given IV 90 secs prior to intubation and 2) esmolol 2.0 $mg.kg^{-1}$ given 60 secs prior to each of gentamycin injection and extubation.

Method: With Ethics Committee approval and patient consent 80 mature age patients were randomised to receive esmolol (E) or placebo (P) Anaesthesia was standardised. Pre-induction HR/SAP was compared with maximum changes after 1) induction and 2) tracheal extubation, end-surgery HR/SAP was compared with maximum changes after 1) eye bandaging, 2) RNB and 3) extubation. Analyses used ANOVA, Chi^2 and 't' tests ($p < 0.05$ significance).

Results: With placebo, HR increased after intubation ($p < 0.001$), RNB ($p < 0.001$) and extubation ($p < 0.001$); SAP fell after induction ($p < 0.01$), increased after intubation ($p < 0.001$), RNB ($p < 0.005$) and extubation ($p < 0.001$) With esmolol, HR decreased after induction ($p < 0.05$) was unaffected by intubation, bandaging and extubation; SAP fell after induction ($p < 0.001$), normalised after intubation, bandaging and RNB, but fell after extubation ($p < 0.001$)

	Pre indu	Post indu	Post intbn	End surg	Post band	Post RNB	Post extbn
P HR	73	79	96	66	71	84	94
SAP	153	127	178	123	141	150	165
E HR	77	69	75	69	65	77	76
SAP	162	117	149	126	127	135	116

* = significant change v preceding baseline. Data = mean value

Conclusion: Esmolol given 60 to 90 secs before these noxious stimuli attenuated rises in HR and SAP, but caused transient hypotension before or after the stimulus. This data suggests that repeat esmolol injection before extubation is unnecessary, and that, in view of the rapid onset of action of esmolol, the timing of esmolol injection in relation to these noxious stimuli needs studying

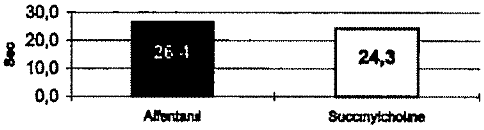
A.76 Intubation without muscle relaxants in Mallampati grade III and IV patients with mandibular fracture

J Kalinowski, I Furman, M. Mikaszewska, R Uryszek,
E. Mayzner-Zawaczka. *Department of Anaesthesia and Intensive Care, Warsaw Medical Academy, Poland*

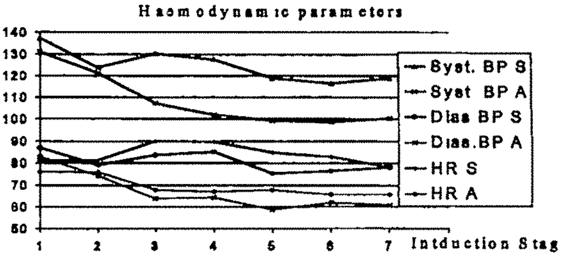
Background and Goal of Study: Intubation without muscle relaxants (MR) gains more and more wider acceptance but there is still a lot of controversy for what types of patients it is suitable. Patients with mandibular fractures are presenting with Mallampati III and IV grades, caused mostly by pain The local survey showed them to be considered by anaesthesiologists as not suitable for induction without use of MR The present study aims to address this issue.

Materials and Methods: After obtaining Ethics Committee approval 52 patients (ASA I/II) were randomly allocated to two groups 26 patients each Patients received propofol 2 mg/kg and alfentanil 0.5 mg/kg for induction, in I group, and propofol 2 mg/kg and succinylcholine 1.5 mg/kg in II, and were intubated via nasal route. The same pre-induction routine was used in both groups. The laryngoscope grade, ease and duration of intubation, and haemodynamic (HD) parameters such as BP, HR, and Sat O_2 were assessed.

Results and Discussion: In both groups intubation was regarded as easy by performing anaesthesiologists The mean time to perform intubation, was 26 4 sec in alfentanil and 24.3 sec in succinylcholine group.



The mean laryngoscope grade was 1.7 and 1.3 respectfully. The HD parameters and oxygenation were evaluated.



Sat O_2 was maintained between 98% and 99% in both groups

Conclusions: Intubation without MR is possible in the group of patients with mandibular fracure and can be perform as easily and quickly as with MR which gives us useful alternative for induction of anaesthesia in this patient group. *Anaesthesia*, **general***Intubation, tracheal, nasal**Drugs,* **propofol, alfentanil, succinylcholine**

A.77 Safety and simplicity of difficult tracheal intubation management: comparison of the Bullard laryngoscope with the video-optical intubation stylet in a mannequin

M. Weiss, U Schwarz, A.Ch. Gerber *Department of Anaesthesia, University Children's Hospital, Zurich, Switzerland*

Background and Goal of the Study: The Bullard laryngoscope (BL) has been reported as a valuable aid in the management of the unpredicted difficult tracheal intubation.[1] The video-optical intubation stylet (VOIS) is a new indirect laryngoscopic intubation device, designed for the management of difficult direct laryngoscopy.[2] It transmits the view from the endotracheal tube (ETT) tip to a video display. This allows the anaesthetist during difficult intubation to guide the ETT into the trachea under visual control. The purpose of this study was to ascertain, if the VOIS is safer and easier to master than the BL

Material and Methods: A mannequin has been adjusted so that only the tip of the epiglottis was just visible using a Macintosh blade (grade III view) 40 anaesthetists of different years of experience were asked to attempt tracheal intubation using the BL and the VOIS One demonstration was followed by one practical attempt. Then each anaesthetist performed each technique 10 times in succession (order randomized). Time was recorded of each attempt. Failed intubations were defined as those, which required more than 60 s or which resulted in esophageal intubations At the end of each sequence the anaesthetists were asked to attach a degree of difficulty using a scale from 1 (extremely easy) to 5 (impossible) The results were statistically evaluated using Mann-Whithey-U-test and Pearson-Chi-square-test

Results:

	Bullard	VOIS	p
Successful intubations	359/400	392/400	0 003
Failed intubations	41	8	0.003
Oesophageal intubations	21	1	0 003
Intubation time (s)	19.2 ± 4 5	18 8 ± 4 6	ns
Degree of Difficulty	2 63	1 68	0.0001

Discussion and Conclusions: Because of fewer failed intubations and a lower degree of difficulty, management of difficult tracheal intubation seems to be safer and easier with the video-optical intubation stylet, than with the Bullard laryngoscope. Our results suggest, that VOIS could become a valuable aid for unpredicted difficult intubations with very little training.

A.78 Evaluation of McCoy laryngoscope in routine laryngoscopy

D. Francon[1], P. Guerre-Berthelot[1], V.J. Bardou[2], J.L. Blache[1] *[1]Dpt of Anaesthesia, [2]DMI-Paoli-Calmettes Institut 232 bd de Ste Marguerite 13009 Marseille, France*

Introduction: The use of the Mc Coy levering laryngoscope is associated with significantly less force required during laryngoscopy. The purpose of this study was to investigate whether the tip elevation results in better laryngeal visualisation during routine laryngoscopy.

Methods: During six months, 300 adult patients, undergoing elective surgery, were investigated in a prospective and descriptive study. The patent upper airway was appreciated with preoperative assesment tests. body mass index, mouth opening, Mallampati classification, neck movement and thyro-mental distance Patients with a known difficult intubation, with risk of regurgitation and with airway assesment test of impossible intubation were not included. All laryngoscopies were performed by nine confirmed anaesthetists with experience in the use of Mc Coy laryngoscope. Each anesthesia was standardised with lidocaine IV (1.5 $mg.kg^{-1}$) and propofol (5 $mg.kg^{-1}$). Head and neck were positioned in the "sniffing" position. The Mc Coy blade (size 3 or 4) was used and the laryngeal view was evalued with Cormack score, in five successive situations. The two first without levering tip as an ordinary Macintosh blade: S1 with usual forwards and upwards elevation of the oro-pharyngeal structures and S2 with elevation and anterior laryngeal pressure. The three next with levering tip: S3 without and S4 with usual elevation, S5 with elevation and anterior laryngeal pressure. The results of Cormack score were colliged in each situations ANOVA including repeated measures was applied to compare the results between different situations.

Results: ANOVA showed statistical significant differences between S5 and the others situations ($p < 0.001$)

	Without tip elevation		with tip elevation		
	S1	S2	S3	S4	S5
Grade I	62	193	14	110	257
Grade II	144	91	128	154	42
Grade III	90	16	145	36	1
Grade IV	4	0	13	0	0

S1 vs S3 $p < 0 001$, S2 vs S4 $p < 0 001$, S2 vs S5 $p < 0 001$

Discussion: Without any applied forces on the handle to expose glottic aperture, levering tip is not sufficient to see correctly vocal cords (S3) In clinical practice with a standardised intubation condition, use of the activated Mc Coy blade with additional manoeuvres as ALP (S5) gave best laryngeal views

A.79 Difficult airway management in cardiac anaesthesia: the role of transillumination guided intubation

A. Gille, T. Alexander. *Department of Anesthesia, Heart Institute Lahr, Germany*

Background and Goal: As a result of further development of the intubation device (Trachlight®, Laerdale), the transillumination guided intubation (TGI) presents itself as an alternative to the direct laryngoscopic intubation [1] Especially cardiosurgical patients require a hemodynamically stable induction, also under complex laryngoscopy. Does the TGI with the Trachlight® present itself as an assistance especially in regards to difficult laryngoscopy conditions?

Methods: Cardiosurgical patients (NYHA III and IV) were induced with Etomidate, Midazolam, Sufentanil and Pancuronium. After the first futile intubation attempt by means of direct laryngoscopy (with non-adjustable vocal cord level) application of the Trachlight® for TGI performed by an experienced specialist Recorded parameters: success, duration, blood pressure, heart rate.

Results: Out of 1034 patients (June–November 1997) 22 patients which could not be directly intubated by laryngoscopy (vocal cord level and arytenoid cartilage not visible, were a part of the study. In 18 cases (82%), the light guided intubation was successful as secondary procedure. In 4 cases, after failure of the TGI, the direct laryngoscopic intubation was performed after 2 attempts in each case. The directly measured arterial blood pressure elevated by 15% in comparison with the pressure prior to the passage through the larynx, the heart rate did not change. In 10 cases, the duration was less than 30 s, in 8 cases 30–60 s

Discussion and Conclusions: After sufficient familiarization of 2 specialists with the technique of the TGI, the TGI was introduced as an alternative in case of difficult intubation because of the positive experience [2]. The lack of transillumination effect with adipose patients could be adjusted by dimming of the induction room. The method does not replace the absolutely safe command of the conventional direct laryngoscopy, as indicated by the 4 failures. The smooth and successful outcome in 82% of the cases disclosed however, that the transillumination guided intubation was a rapid uncomplicated assistance in case of difficult intubation conditions

A.80 The double lumen tube. Indications, application, monitoring (A video film)

K. Wiedemann[1], U Klein, H.D. Becker, R. Gottschall. *[1]Thorax Clinic, Dept. of Anaesthesiology and Intensive Care, Heidelberg, Germany*

This video aims at inducing familiarity with an important anaesthetic tool· In 1949 E. Carlens for the first time used a double lumen tube (DLT) to prevent the intraoperative spread of tuberculous secretions from the affected into the healthy lung. Absolute indications for airway separation are haemoptysis, bronchiectasis and tracheobronchial fistula, while relative indications all refer to optimizing surgical conditions This traditional distinction no longer is justified considering the surgical precision required, the importance of endoscopic thoracic surgery and the improvement in design and material of DLT's

In this video film the modern polyvinyl right and left-sided DLT's are described in detail, also the correct course of their insertion is exemplified by endoscopic visualization. Clinical checks by auscultation and inspection of DLT-position frequently prove unreliable, as in 15% of our own cases Often primary misplacement into the wrong main bronchus, too far outside or too far down the correct main bronchus cannot be detected clinically By fibreoptic bronchoscopy (FOB), however, a correct position can be verified, malpositions identified and thus corrected immediately. Videobronchoscopic takes from bronchiectases and bronchial sleeve resections serve to demonstrate the importance of the availability of fiberoptic bronchoscopic control of the double lumen tube, since only DLT's offer every option of conventional and differential management of one-lung ventilation, as CPAP or High Frequency Jet Ventilation to the non-dependent, operative lung. Sequences of clinical examples, endoscopic views and computer animations demonstrate how to combine DLT's and FOB into a safe and reliable system for the management of ventilation in non-cardiac thoracic surgery.

A.81 Intubatin laryngeal mask airway (Fastrach®): the learning curve of its use

N. Palgimesi, A. Bairaktari. *Dept of Anaesthetics, Piraeus General Hospital,*

Background and Goal of Study: Laryngeal Mask Airway (LMA) has been widely used as an alternative way to ensure airway patency during anaesthesia and resuscitation. The insertion of a LMA is a skill that is easily taught even to inexperienced operators [1] A new modification of the LMA, the Intubating Laryngeal Mask (ILM) Fastrac®, has been developed. It is consisted of a handle, a rigid anatomically curved airway and an epiglottic elevator through which blind endotracheal intubation can be performed. The goal of this study was the assessment of the initial experience of ILM and the documentation of the learning curve of its use.

Materials and Methods: 60 patients scheduled for surgery, Mallampati class I–III, were selected for ILM insertion and subsequent blind endotracheal intubation by two anaesthetists with a wide experience in LMA and with experience only in training manikins in ILM. After the induction of anaesthesia with propofol, insertion of an ILM size 3, 4 or 5 according to the patient weight was attempted When adequate ventilation was established, an endotracheal armoured tube 30–32 Fr was blindly inserted through the ILM. Throughout the procedure a) the number of attempts required for successful ILM placement b) the success rate of blind endotracheal intubation through the ILM c) details that facilitated the insertion technique d) the time required for the procedure were recorded and documented. After the collection of the data, we drew the learning curve of ILM use for both the anaesthetists.

Results and Discussion: 34 male and 26 female were studied. ILM insertion and adequate ventilation was possible at the first attempt in 53 and second attempt in 7 patients. Blind endotracheal intubation was achieved in 49 patients (after 1 atttempt in 41 and after 2 attempts in 8), and failed in 11 patients The entire procedure lasted 45–90 sec Failed intubations were due to errors of the technique, misplacement of the ILM and, as it was presented by the learning curves, to lack of experience because all the failures were associated with the first patients of the study

Conclusion: The new ILM is very easily inserted in patients. The blind endotracheal intubation through the ILM is a more difficult skill in which success rate is being improved by experience.

A.82 How to choose the adequate size of a left-sided double-lumen endobronchial tube. An assessment of the radiographic Brodsky's method

M Landi[1], X Baron[2], H. Lanquetot[1], J. Fusciardi[1] [1]*Dept of Anaesthesiology, University Hospital of Poitiers, 86021 Poitiers;* [2]*Dept. of Anaesthesiology, Saint Louis Hospital, 17000 La Rochelle, France*

Introduction: Brodsky and al (1) showed that adequate DLT' size can be successfully selected from measurement of the tracheal width on a preoperative posterio-anterior chest radiograph However, we believe that determination of adequate DLT' size must include the followings· difficulties in insertion (DI), fiberoptic bronchoscopic control of adequate catheterization of left main bronchus (FOB), adapted impervious bronchial cuff volume (BCV) and no postoperative tracheal injury (POTI). The aim of our study was therefore to assess the Brodsky and al's method, taking into account the above criteria

Materials and Method: 47 consecutive patients included for planed thoracic surgical procedures with one-lung ventilation were intubated under general anaesthesia with polyvinyl chloride DLT. The choice of the DLT'size was based on radiographic front tracheal width (RTW) according to Brodsky and al (1): 41 French (Fr) when RTW ≥ 18 mm, 39 Fr when RTW ≥ 16 mm, 37 Fr when RTW ≥ 15 mm. Adequate DLT's position was controlled with fiberoptic bronchoscopy. Impervious bronchial cuff volumes were adapted to obtain both a bronchial cuff pressure ≤30 cm H2O and no ventilatory leak. In addition, difficulties in DLT's insertion (passing through glottis, advancing down the trachea), postoperative endotracheal injury (laryngitis or tracheitis needing treatment, sore throat) were noted.

Results: Sex ratio (M/F) was 33/14 All patients were successfully intubated with predicted DLT'size. Adequate lung deflation was obtained in every case No ventilatory leak was noted. Other results are shown on the table. no statistical difference linked to DLT'size was observed.

DLT'size (french)	n (M/F)	DI (%)	FOB (%)	BCV (ml ± SD)	POTI (%)
41	36 (30/6)	26	100	1 7 ± 0 5	27
39 ± 37	11 (3/8)	9	100	1 7 ± 0 6	18

Discussion-Conclusion: It is confirmed that the adequate DLT'size can be selected on the basis of radiographic data; since all patients were successfully intubated with predicted DLT'size with adequate placement and impervious bronchial cuff volume for cuff pressure ≤30 cm d'H2O. Moreover, neither difficulties in insertion nor tracheal injuries depended on DLT'size. Postoperative injuries were limited to temporary sore throat.

A.83 A new modality of high-frequency ventilation: superposition of two jet streams

G Ihra, A. Kepka, P. Kraincuk, C. Schabernig, A. Aloy. *Dept. of Anaesthesiology and Intensive Care Medicine, University of Vienna, Austria*

Background and Goal of Study: High-frequency jet-ventilation techniques have been introduced as alternative ventilatory modalities during laryngeal and pulmonary surgery and to improve impaired oxygenation (1). However, small tidal volumes delivered at high respiratory rates result in increased levels of arterial CO_2. Therefore, we combined two seperate jet-streams (superposition) with different rates via a special T-connector, enabling normal CO_2 elimination

Materials and Methods: In the perioperative course 33 surgical patients (40 ± 18 yrs) with normal pulmonary function were ventilated with an electronic prototype high-frequency jet-ventilator (Alexander I, Reiner, Austria). Patients were submitted to superimposed high-frequency jet-ventilation (SHFJV) with respirator settings comparable with the preceeding conventional mechanical ventilation (identical FiO_2 and airway pressures) To increase tidal volume a low-frequency (8–14/min) jet-stream and a high-frequency (600/min) jet-stream were applied simultaneously via a special jet-adapter connected to the conventional endotracheal tube. For gas entrainment due to the Venturi effect a bias flow of 15 L/min of humidified and warmed gas was lead through the cross part of the jet-adapter. Data of blood gas analysis (paO_2, $paCO_2$), heart rate (HR) and mean arterial pressure (MAP) during conventional ventilation (CPPV) and after one hour of subsequent SHFJV were compared Data (mean ± SD) were analyzed using the paired *t*-test ($p < 0\ 01$)

Results: SHFJV resulted in increased levels of paO_2 (121 ± 34 *vs* 145 ± 44 mmHg) and decreased values of $paCO_2$ (40 ± 5 *vs* 32 ± 6) HR (77 ± 25 *vs* 75 ± 26) and MAP (69 ± 12 *vs* 72 ± 12) did not change after transition of ventilation to SHFJV.

Conclusion: SHFJV is safe and effective to improve oxygenation. In contrast to solitary HF jet-, SHFJV also facilitates adequate CO_2 elimination by addition of a low-frequent jet-stream, which increases tidal volume. Therefore, benefits of HF jet-ventilation can be utilized in patients over longer periods maintaining normal CO_2 levels

A.84 A new prototype of an electronic jet ventilator and its humidification system

P. Kraincuk, A Kepka, C Schabernig, G. Ihra, A. Aloy. *Department of Anesthesiology and General Intensive Care, University of Vienna, Austria*

Background & Goal of Study: This study introduces a new prototype of an electronic jet-ventilator named ALEXANDER 1, which is capable of simultaneously delivering two separate jet streams with different frequencies to the patient This ventilation technique is called superimposed high-frequency jet-ventilation (SHFJV) We want to show, that the problems of humidification under SHFJV can be prevented using this new jet-ventilator

Material & Methods: Forty patients, 16 female, 24 male with a median age of 67 years (range 55 to 79 years) were randomly allocated to one of four groups (A, B, C, D) ten in each group, receiving either SHFJV by the ALEXANDER 1 (group A and group B), or high frequency oscillation (HFO) by a VDR 4 (group C), or conventional mechanical ventilation (CMV) by an Evita (group D). All patients were ventilated for more than 100 hours because of respiratory insufficiency.[1]

Measurements of the relative humidity (RH) of the inspiration gas (FM-Cl, E u. E. Elektronik Corp , Unterwiesen, Austria) and measurements of the temperature of the inspiration gas were performed (temperature sensor line 21076 A, Hewlett Packard, Palo Alto, CA) twice a day Bronchoscopy (Olympus BF Type 20D, Olympus Optical Co , LTD, Shirikawa, Japan) was performed twice a day too. Humidification and warming of the ventilation gas was done using three different humidification systems In group A, we used a combined form of a humidification and warming-system Whereas the entrained gas (bias flow) was humidified by a hot water humidifier (Aquapor, Type 8406640, Fa. Drager, Corp., Lübeck, Germany), humidification of the jet gas was achieved by a continous infusion of 0.9% saline via a special jet adapter into the high pressure jet line The instilled saline infusion was warmed by a fluid warmer (HL-90 INT, Level 1 Technologies Corp., Rockland, MA, USA) up to 37°C before it reached the jet gas In group B, we used the same system without the fluid warmer. In group C and D, we used a hot water humidifier In all four groups, several patients were exposed to intermittent prone position in case of extremely severe respiratory distress syndrome.

Results & Discussion: To evaluate the amount of tracheobronchial mucosal injury, a scoring system was used, taking into account the size of the area and the extent of macroscopic epithelial damage. Group A, C and D had a mucosal injury score of zero. No significant pathologic evidence could be seen The temperature values (group A: 31.4°C; group C: 32 1°C; group D 34.2°C) were insignificantly different In group B, the temperature was significantly lower (27°C) than in all the other groups. Inflammation of the tracheal mucosa was found and the mucosal injury score was significantly higher.

Conclusion: Using the ALEXANDER 1 for SHFJV with high humidity almost all the problems, which are associated to this ventilation technique, like tracheal and epithelial inflammation, necrotizing tracheobronchitis (NT), etc can be prevented

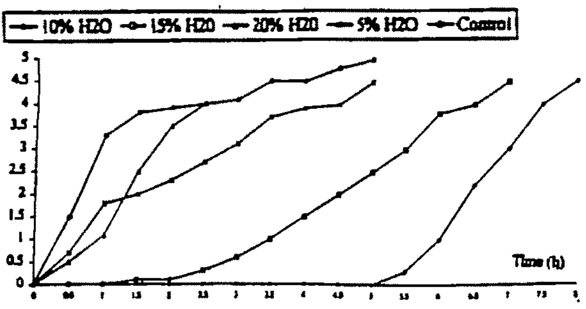
A.85 Carbon dioxide absorption without strong alkali

C W. Renfrew, J M Murray, J P H Fee. *The Department of Anaesthetics, The Queen's University, Belfast, Northern Ireland*

Background and Goal of Study: The interaction between carbon dioxide absorbents containing strong alkali (sodium or barium hydroxide) and volatile anaesthetic agents has recently given cause for concern (1, 2) It has previously been suggested that strong alkali is not required for efficient absorption but that the moisture content of the absorbent is most important (3).

Materials and Methods: Using mixtures of calcium hydroxide and hydrated calcium chloride ($CaCl_2$ $6H_2O$) we produced material with 0%, 5%, 10%, 15% and 20% water content. One hundred grams of the material was placed in a canister and oxygen at 1 l/min with carbon dioxide at 40 ml/min was passed through the material A Datex Capnomac gas analyser was placed at the exit port of the canister and readings were collected directly by a portable computer.

Results: The results are shown as time (hour) against carbon dioxide (kPa).



Conclusion: The water content of a carbon dioxide absorbent is directly related to its ability to absorb CO_2 and strong alkali is not necessarily required.

A.86 Carbon monoxide production in rebreathing circuits: the halogenated concentration effect

C. Bonome, J. Belda, F. Refojo, M Soro, C. Gotti, H Aymerich. *Hospital Juan Canalejo, A Coruña, Spain*

Introduction: The carbon monoxide (CO) production in the rebreating circuits happens when certain halogenated agents reacts with dryness soda lime (hydrate level lower than 2%) However the mainly factors that determine the severity of CO intoxication during the clinical use of a rebreathing circuit have not been studied, one of these factors can be the minute volume

Objective: To determine carboxyhemoglobin (HbCO) and CO levels (in the rebreathing circuit) using desflurane a differents concentrations.

Material and Methods: Six Large-White swine (weight. 36 ± 3 kg) are anesthetized using desflurane at different concentrations (3 5% and 7%). The dried Soda-Lime is gotten carring across the Soda-Lime canister a oxygen flow during 65 h, obtaining hydrated Soda-Lime level = 1% The anaesthesia machine used was an Elsa-engstrom with the Soda-Lime canister in the inspiratory branch and the halogenated agent was isofluorane.

The experimental sequence is the following

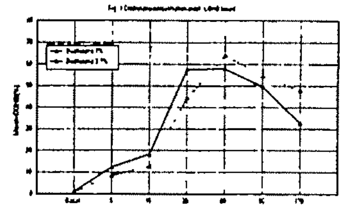
(1) Anesthetic induction and beginning of the mechanical ventilation – fresh gas flow = 8 liters (O2-N2O = 50%), VT = 15 ml/kg and FR = 15-.

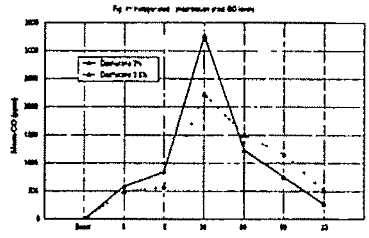
(2) Anesthetic intravenous maintenance and monitoring: TA, PAP, SvO2, ETCO2, sPO2 and T^a.

(3) Change normal hydrated Soda-Lime canister (15%) for dried Soda-lime canister (1%) and opening the desflurane vaporizer to reach an Inspired same us to espired concentration = 7% or 3.5% to the 15 minutes and maintaining these concentrations during the rest of the experience

(4) To the 15 minutes lowered the gas fresh flows to a sixth part of the minute volume until the end of the experience.

We register haemodynamic monitoring data, blood gas measurements and we analyzed the HbCO and the CO (in the Inspiratory branch) levels (basal, 5, 15, 30, 60, 90 and 120 minutes) A descriptive study of the levels of HBCO and of CO (ppm) in the rebreathing circuit was carried out





Results: The peak values of HbCO were obtained in the minute 30 y 60 (Fig. 1) and were different in relation to the desflurane concentration 57 9 ± 05 vs 64 15 ± 5 7, this difference hasn't statistical significance t-test for Equality of Means 95%CI for Diff (–9 907, –2 593). CO peak levels in the circuit was higher in the group of desflurane = 7% but with desflurane 3% the levels were more maintained (Fig 4b)

Conclusion: (1) The CO levels the rebreathing circuits could reach later elevated peaks when low concentration of desflurane were used.

(2) When low desflurane concentrations are used reinhalation and slow production of carbon monoxide are the mainly factors that produce a severe carbon monoxide intoxication.

A.87 Carboxyhaemoglobin concentrations in patients during desflurane anaesthesia using a circle circuit with partially dried soda lime

M. Soro[1], F J Belda[2], A Cortes-Uribe[1], F Alvarez[3], C. Bonome[3]
Anaesthesia and Critical Care Departments; [1] Hospital Virgen de la Salud (Toledo); [2] Hospital Clinico Universitario (Valencia); [3] Hospital Juan Canalejo (La Coruña), Spain

Background and Aim of the Study: Routine use of high fresh gas flow (FGF) in circle circuits (>5 L/min) prevents rapid exhaustion of Soda lime (SL) but reduces its water content (1). Dryed SL reacts with desflurane producing high levels of Carbon monoxide (CO) and carboxihemoglobine (HbCO) (2, 3). Nevertheless, very few cases of CO poissoning has been reported in clinical anesthesia We determine the HbCO levels in patients anesthetized with desflurane in operating rooms in which the anaesthesia machine maintained the same SL in place up to 8 weeks, provided that no CO2 rebreathing was observed

Material and Methods: We study 12 consecutive patients scheduled for elective surgery after obtaining their informed consent Anesthesia was maintained with desflurane 7% using a Ohmeda Excell-210 machine and GMS absorber circuit with standard double canister (1.350 g SL each) Two circuits were used: one having SL in place since 4 weeks and another one since 8 weeks. With the 4 weeks-SL circuit, 4 patients were anesthetized maintaining a constant FGF of 7 L/min In other 4 patients FGF was reduced to 2 L/min after 15 min of anaesthesia (when end-tidal desflurane reached 7%) Whith the 8 weeks-SL circuit, 4 patients were anesthetized using a constant FGF of 7 L/min (lower FGF produced CO2 rebreathing). Arterial blood samples were obtained after induction (control) and after 5, 15, 30, 45 and 60 min of anaesthesia. For safety reasons samples were inmediately processed in the operating room for HbCO by cooximetry (OSM3 Hemoximeter, Radiometer, Copenhagen) Water content of SL was determined prior to anesthesia in 50 g samples obtained from the upper, middle and lower layers of the canisters, using a moisture balance (Ohalls MB-200, N Jersey, USA).

Results and Discussion: SL water content (% ± SD), and HbCO (% ± SD) values are presented in the tables In spite of the very low SL water content in the upper and lower layers of the 8 weeks-SL, all HbCO determinations were in the normal range (1–2%) in contrast to the high HbCO levels (up to 50%) found in experimental studies using homogeneous 1.5% dryed SL (2). This can be explained because the higher hydration levels of SL in the middle layer could mitigate the effect of the other layers, avoiding CO production. The capacity of the canister and the flow conditions are factors that play a major role to produce more critical or homogeneous dryness of SL (and could explain the few reported clinical incidents) In fact, we saw that a continuous flow of 7 L/min through a single small SL canister (950 g) for just 41 hours produced a critical dryness level, homogeneously in the three layers (1) But for this to ocurr using the same canister in clinical anesthesia, it would take a longer time than needed for SL exhaustion that will produce CO2 rebreathing earlier. This was observed in our study with the 8 weeks-SL

% water	4 weeks	8 weeks
Upper	8.6 ± 0.2	1.3 ± 0.2
Middle	11.8 ± 0.2	2.5 ± 0.2
Lower	7.1 ± 0.2	1.6 ± 0.2

	%HbCO	Control	5 min	15 min	30 min	45 min	60 min
4 weeks-SL	FGF HI	0.1 ± 0.2	1.4 ± 0.2	1.4 ± 0.2	1.3 ± 0.2	1.2 ± 0.2	0.6 ± 0.2
	FGF Lo	0.9 ± 0.2	1.0 ± 0.2	1.0 ± 0.2	1.0 ± 0.2	1.0 ± 0.2	0.9 ± 0.2
8 weeks-SL	FGF HI	1.0 ± 0.2	1.3 ± 0.2	1.1 ± 0.2	1.3 ± 0.2	1.0 ± 0.2	1.1 ± 0.2

Conclusion: The use of double high-capacity canisters in circle circuits seems to prevent homogeneous critical dehydration of SL due to long periods of clinical use with high FGF regimes. This could avoid CO production under desflurane anesthesia.

A.88 Sodium hydroxide is a factor in the production of carbon monoxide when dried soda lime is exposed to desflurane, enflurane and isoflurane

C W. Renfrew, J M Murray, J P H. Fee *The Department of Anaesthetics, The Queen's University, Belfast, Northern Ireland*

Background and Goal of Study: The interaction between carbon dioxide absorbents containing strong alkai (sodium hydroxide) and volatile anaesthetic agents has recently given cause for concern (1, 2). A mixture of calcium hydroxide and hydrated calcium chloride ($CaCl_2$ $6H_2O$) containing 10% water has been found to absorb carbon dioxide. The aim of this study was to assess the production of carbon monoxide when desflurane, enflurane and isoflurane were exposed to a dried sample of the above mixture and conventional sodalime.

Materials and Methods: Sodalime (Intersorb™) or the new mixture were heated in an oven at 250°F for eight hours. A gas mixture of oxygen/nitrous oxide in a 50:50 mix at a flow of 1 l/min with desflurane, enflurane or isoflurane at 1 MAC and CO_2 at 40 ml/min was passed through a canister containing 100 g of each absorbent. After 1 minute a 2 1 sample of the gas was collected and analysed for carbon monoxide content

Results: The table shows carbon monoxide content of the collected gas.

	Sodalime	New mixture
Desflurane	600 ppm	1 ppm
Enflurane	580 ppm	1 ppm
Isoflurane	620 ppm	2 ppm

Conclusion: The presence of sodium hydroxide is a factor in the production of carbon monoxide produced when desflurane, enflurane and daesflurane are exposed to dried carbon dioxide absorbents.

Dr C Renfrew was in receipt of a Research Fellowship from the Ulster Hospital, Dundonald, N Ireland.

A.89 Effect of using dry carbon dioxide absorbent in a rebreathing anaesthesia circuit for sevoflurane

S. Chang, K Cromack, D Grabenkort, V. Lafita, D. Pecosky, R. Raph, M. Richardson, V. Rubinshteyn, M. Stramaglia *HPD, R & D Abbott Laboratories, Abbott Park IL, USA*

Background & Goal of Study: It has previously been reported that carbon monoxide forms via reaction between inhalation anesthetics and CO_2 absorbents.[1] Fang's study showed that desflurane, enflurane and isoflurane produced substantial quantities of CO; whereas, halothane and sevoflurane produced only minor quantities of CO. More recently, others have seen enhanced reactions of these anesthetics with very dry CO_2 absorbents, but the analytical results on the degradants produced, in particular Compound A, have been questionable.

Material & Methods: Dry Soda lime (<2.5% moisture) was loaded into two CO_2 absorbent canisters in an anesthesia machine. Thermocouples were placed in the soda lime and at the patient Y tube to record temperature profiles. Datex Gas Monitors were connected to determine the compositions of fresh gas, inspiratory gas and expiratory gas. A flow of 2.2 L/min of 8% sevoflurane was initiated with 7.5 L/min total recirculated volume 0.3 L/min of CO_2 was added to the Y tube to simulate the patient's expiratory gas. Samples of inspiratory gas were taken periodically for 3 hours using gas tight syringes. Samples were tested for carbon monoxide, Compound A and sevoflurane potency using validated GC methods.

Results & Discussion: Parts of the CO_2 absorbent bed reached a temperature of but the highest temperature at the patient mouthpiece was only Forty minutes into the experiment, the top canister had turned dark purple which indicated that the CO_2 absorbing capacity in top canister had been exceeded. The CO_2 detected on Datex Gas Monitors indicated that CO_2 absorbing capacity of both canisters was exhausted at 80 minutes. Carbon monoxide was produced during the first 120 minutes reaching a maximum concentration of 536 ppm at 80 minutes. Compound A does not increase until the CO_2 absorbent is exhausted, reaching a maximum concentration of 68 ppm at 90 minutes.

Conclusion: Our study has demonstrated that the Compound A increase corresponds to the CO_2 absorbent's exhaustion Standard practice suggests that the CO_2 absorbent would be changed before the indicator color change occurs or at least when it is first noticed. To date, there is no clinical evidence to indicate that the generation of Compound A from the reaction of sevoflurane with dry soda lime is of concern

A.90 Dry soda lime heavily degrades sevoflurane during inhalation induction

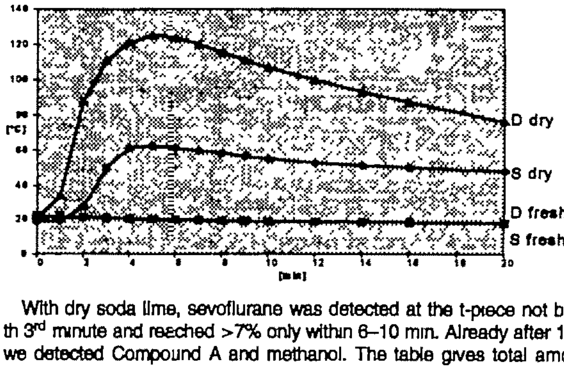
W. Funk, M. Gruber, K. Taeger, J. Hobbhahn. *Department for Anaesthesiology University of Regensburg,*

Sevoflurane is partially degraded by hot soda lime (1). Recently (2), there have been two interesting communications:

1) Failure of induction coincident with a remarkably slow rise in concentration at the T-piece despite a high setting of the vaporizer. 2) Severe airway irritation during inhalation induction. To elucidate possible mechanisms we investigated the gas composition during simulated inhalation induction.

Material and Methods: Using a conventional Draeger circle system, 8% Sevo in 6 l/min O_2 were washed into an absorbing canister (1l, Draeger) filled with fresh or dried soda lime with 2.9% (Draegersorb 800, "D") or without KOH (<0.01%, Sofnosorb, Molecular Products, "S"). Drying was achieved simulating possible clinical handling errors (6–15 l/min O_2 for 20–34 hours, total 15000 l). Gas samples were drawn every minute for 20 min at the T-piece. The gas was then directed through bubble flasks to catch hydrophilic degradation products Analyses were performed using GC/MS or FID with appropriate standards (Comp A:sd ± 14%, CH_2OH:sd ± 8%), an ISE (F) and a test kit (H_2CO, Aquamerck)

Results:



With dry soda lime, sevoflurane was detected at the t-piece not before th 3rd minute and reached >7% only within 6–10 min. Already after 1 min, we detected Compound A and methanol. The table gives total amounts (mg) during 20 min.

	Methanol	Formaldeh	Fluoride
S fresh	not detec.	not detect	≥1.9
D fresh	not detec.	not detect	≥1.3
S dry	88	not detect	≥3.3
D dry	789	≥2.3	≥8.5

Conclusion: During inhalation induction with Sevoflurane the use of fresh soda lime is of crucial importance With dried soda lime, the patient may inhale potentially toxic substances in significant amounts. Degradation is aggravated by a high KOH content of the lime. Temperatures above 50°C promote further degradation (3). The observed airway irritation may be caused by formic acid, which is generated in isomolar concentrations with methanol (Cannizzaro-reaction) and not by HF, which reaches the t-piece in low quantities only. The unexpectedly high amounts of Comp A deserve further study

A.91 Sevoflurane is not degraded during *In vitro* low-flow anaesthesia using a sodium hydroxide-free absorbent

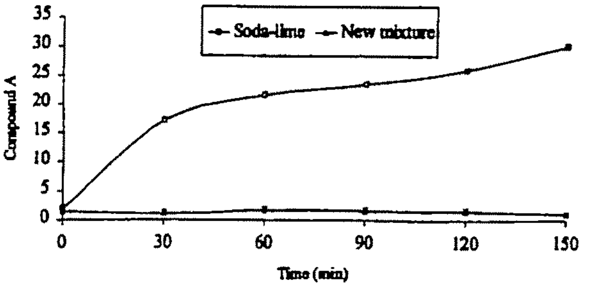
C.W. Renfrew, J.M Murray, J.P.H. Fee *The Department of Anaesthetics, The Queen's University, Belfast, Northern Ireland*

Background and Goal of Study: The interaction between carbon dioxide absorbents containing strong alkali (sodium hydroxide and barium hydroxide) and volatile anaesthetic agents has recently given cause for concern (1, 2) A mixture of calcium hydroxide and hydrated calcium chloride ($CaCl_2.6H_2O$) containing 10% water has been found to absorb carbon dioxide. The aim of this study was to assess the production of compound A during in vitro low-flow sevoflurane anaesthesia using the new mixture.

Materials and Methods: An in vitro experiment was performed where a 50 50 gas mixture of oxygen/nitrous oxide with 1 MAC sevoflurane was flowed through a canister containing either 100 gm of sodalime (Intersorb™) or 100 gm of the new mixture. Three gas samples were removed from an exhaust port distal to the canister at 30 minute intervals into gas tight syringes and were analysed by gas chromatography for compound A concentrations.

Results: The results are shown in the figure as time (min) against compound A concentration parts per million (mean (SD))

Conclusion: Compound A is not produced in an in vitro low flow system containing sodium hyroxide free absorbent for CO_2 absorption.



Dr C Renfrew was in receipt of a Research Fellowship from the Ulster Hospital, Dundonald, N Ireland

A.92 Xenon anaesthesia in humans: expenditure and recycling

A. Ferran, F. Giunta *Chair of Anaesthesiology and Intensive Care, Dept of Surgery, University of Pisa, Italy*

Background and Goal of the Study: The noble gas Xenon (Xe) has been used to perform general anaesthesia since 1946 With the low blood/gas partition coefficient (0.14) and a MAC of 71%, Xe offers rapid induction and recovery from anaesthesia. Moreover Xe shows potent anaesthetic and analgesic properties, it is non explosive, non toxic and it does not undergo biotrasformation. Were it not for high cost, Xe would be a valuable alternative to nitrous oxide. The goal of our study was to determine Xe expenditure and to validate a Xe purifying and recycling system

Material and Methods: 15 patients (8 men, 7 women, age 22–77 years, 52–100 kg, ASA I–II) undergoing abdominal surgery, general anaesthesia lasting 40 to 320 min.

Xe anaesthesia has been performed by two different systems: Modulus Plus Ohmeda (Madison, Wi) (4 patients) and PhysioFlex Drager (Physiomedical System BV, Hoofddorp, NL) (11 patients) Xe was administered via an adapted rotameter The use of a low-flow or a totally closed circuit could permit an easy Xe recycling for the small amount of expired gases, collected in gas thight plastic bags. Moreover Xe uptake breath by breath during anaesthesia with PhysioFlex was obtained by the software Flexcom 5 (Physiomedical System BV, Hoofddorp, NL), also used for other data collection (VO_2, $EtCO_2$, peak, mean and plateau pressure). Xe percentage was also directly measured by a thermic-conducimeter for gas analysis.

A process and an apparatus for purifying and recycling Xe was setup together with SIAD Co. (Bergamo, Italy)

Results and Discussion: In the first 15 min (filling of the circuit after a denitrogenation in Oxygen 100% for 20 min.) Xe expenditure was 11 1 litres, from 15 to 60 min 3 litres, then 3 2 litres for each hour The data show a low supply of Xe after the filling of the circuit, according to the biochemistry and pharmacokinetics of Xe

The result of our recycling technique was a recovery of more than 90% of Xenon

Conclusions: Xe supply and its high cost seems to be the only problem for a routine utilization, In fact Xe is a rare gas present in the athmosphere in a very low concentration Recycling appears as the main solution to all these problems

A.93 Comparison of isoflurane-clonidine, desflurane-clonidine and sevoflurane-clonidine association in middle ear surgery

S Aunac, P E Pendeville, P. Gourdange, M.J Van Boven. *UCL Medical School, Brussels, Belgium*

Introduction: Alpha2 agonists are considered as true anaesthetic products Their association with inhaled agents is appraised for the excellent haemodynamic stability induced. This stability is associated with a superficial capillary constriction which offers the surgeon a dry operating site and participate to the success of the procedure One can however regret a marked sedation. Therefore we tried to evaluate desflurane and sevoflurane associated with clonidine in comparison with the association isoflurane-clonidine.

Methods: 60 ASA I or II patients were enrolled The patients were randomised in 3 groups. General anaesthesia was induced with propofol 2 5 mg/kg and sufentanil 0.3 μg/kg Atracurium 0.4 mg/kg was administered for muscle relaxation. Anaesthesia was maintained with isoflurane (group I), desflurane (group D) or sevoflurane (group S) with a mix of O_2/N_2O. After induction every patient received a loading dose of clonidine (4 μg/kg above 30 minutes) followed by a continuous infusion of 1 μg/kg/hr. This infusion was stopped as the graft was positioned Blood pressure and heart rate were recorded every 5 minutes Bleeding was assessed by the surgeon (VAS) at three times incision (T1), dissection (T2), graft positioning (T3). Recovery of cognition and emergence speed were also evaluated Statistical analysis was performed using ANOVA and Chisquare test.

Results: The three groups were comparable according to patients parameters, duration of anaesthesia, operating time, haemodynamic parameters and total doses of propofol, sufentanil and atracurium. Bleeding scores show a significant difference between isoflurane and desflurane with advantage for last one (table1). There was no significant difference concerning times between pure oxygen and extubation, opening eyes or shaking hand. Nevertheless trend for quicker recovery was noted with desflurane (table2).

Conclusion: Whatever the choice is between the 3 inhaled agents, it does not act upon the recovery profile, even though scores in the desflurane group tend to be best. Bleeding appears to be lesser in the desflurane group.

Table 1· Comparison of bleeding in the three groups

	T1	T2	T3
Group I/Group D	0 034	0 001	0 003
Group I/Group S	0 026	NS	NS
Group D/Group S	NS	0 058*	0 023

*Trend for a significant difference

Table 2· Recovery times and emergence profile

Times (min) for	Group I	Group D	Group S	D/I	D/S
Extubation	11.7 ± 4 5	10 4 ± 4 8	13 2 ± 6 5	NS	NS
Opening eyes	11 1 ± 5	9 9 ± 4 7	14 ± 6 4°	NS	0 052
Shaking hand	13 8 ± 7	11 6 ± 4 9	16 ± 7 2°	NS	0 053
Recall birth date	17 6 ± 7 4	15 6 ± 5 6	20.4 ± 9 6°	NS	0 082

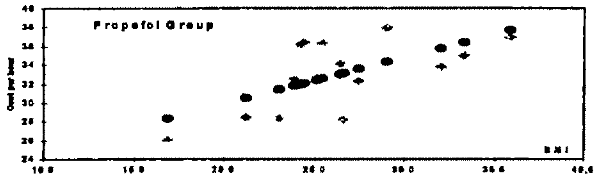
A.94 Influence of somatometric parameters on anaesthesia cost

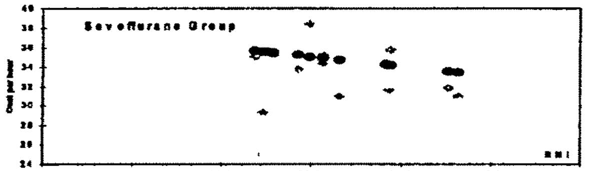
F Kanakoudis, S Foka, S. Spathopoulou, A. Petru *Theagenio Anticancer Hospital, Thessaloniki, Greece*

Background and Goal of Study: Cost of anaesthesia tends to affect modern anaesthetic practice. Especially when drugs with short recovery times which do not delay patient's discharge are used, the parameter cost becomes even more important.[1] The following prospective, randomized study was conducted in order to evaluate the cost of two anaesthesia techniques with modern anaesthetics (propofol or sevoflurane) in relation to patient's somatometric data.

Materials and Methods: After approval from the hospital's ethical committee, 30 patients who were to undergo laparotomies under general anaesthesia were randomly allocated to receive propofol or sevoflurane as main anaesthetic agent. Induction to anaesthesia was achieved with propofol supplemented with small doses (10–20 μg) of sufentanil. Anaesthesia was maintained by either continuous infusion of propofol (Propofol group, n = 15) or Sevoflurane (Sevoflurane group, n = 15) both supplemented by nitrous oxide (66%) in oxygen with a fresh gas flow of 6 L/min and sufentanil in incremental doses (10 μg). Cis-atracurium was used for muscle relaxation. Drugs doses and consumption were recorded and cost analysis (in $ US per hour of anaesthesia) was done according to the hospital's current prices. The relation between anaesthetic consumption and Body Mass Index (BMI) was tested with regression analysis test ($p < 0.05$) and corresponding curves were constructed Student t-test was used for comparisons between groups

Results and Discussion: In Propofol group, patients were of 59 ± 16 years of age, with a BMI of 26.3 ± 4.8 and the duration of anaesthesia was 135 ± 17 min. In Sevoflurane group, patients were of 49 ± 11 years of age, with a BMI of 26 6 ± 3.3 and the duration of anaesthesia was 134 ± 24 min. No statistical significant differences were found between groups. In Propofol group (mean infusion rate of 0.6 ± 0 1 mg/kg/min) a positive correlation between BMI and propofol consumption was shown ($p = 0.011$) but in Sevoflurane group (mean concentration in FGF of 1 5 ± 0.2%) no significant correlation was proved ($p = 0.488$).





Conclusion: As the cost of maintenance of anaesthesia with Propofol seems to be related to body weight, and that of Sevoflurane anaesthesia does not, it might be cost effective to choose Sevoflurane in patients with high or above normal BMI and to reserve propofol infusions for patients with low BMI.

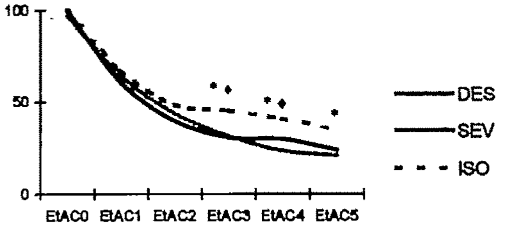
A.95 Elimination of isoflurane, desflurane and sevoflurane after prolonged anaesthesia

N. Molins, A Pensado, P. Rama, A. Vázquez-Fidalgo, S. Garrido, P. Pose. *Department of Anaesthesia, Hospital Juan Canalejo, La Coruña, Spain*

Background & Goal of Study: Desflurane (DES) and Sevoflurane (SEV) shown lower solubility and a theorical faster elimination than other halogenated anaesthetics The aim of this study was to compare the elimination after with DES, SEV or Isoflurane (ISO) anaesthesia in long-lasting open urological procedures.

Material & Methods: Sixty-seven patients ASA 1, 2, 3 were enrolled in this study. Anaesthethic induction was achieved with thiopental, fentanyl and vecuronium After orotracheal intubation the patient's lungs were ventilated with 60% N_2O in oxygen (6 lpm fresh gas flow). The patients were randomly assigned to group DES (n = 23), SEV (n = 22) or ISO (n = 22) for maintenance of anaesthesia and anaesthetic concentration was adjusted to mantain arterial pressure and heart rate within 20% of baseline value. Age, gender, ASA, fentanyl dose, anaesthesia duration, MAC-hours and end tidal anaesthetic concentration (EtAC) at the end of surgery expressec in MAC ($EtAC_0$) were recorded Anaesthetics agents were discontinued and fresh gas flow was mantained with oxygen 100%. Then we recorded the EtAC every minute for five minutes ($EtAC_1$ – $EtAC_5$) expressed in % of $EtAC_0$. Fisher exact test and ANOVA with Bonferroni correction were used for statistical analysis. Data are expressed as mean ± SD and $p < 0.05$ was considered significant

Results: There were no diferences betwen groups in patients age, gender, ASA, total dose of fentanyl, anaesthesia duration, MAC-hours, and EtAC0. EtAC were lower for DES and SEV groups than for ISO group at minutes 3 and 4, and for DES group than for ISO group at minute 5. There were no diferences between DES and SEV groups (figure).



*p <0.05; DES vs ISO at min 3,4 and 5
♦ p<0 05, SEV vs ISO at min 3 and 4

Conclusión: In our experience, both Desflurane and Sevoflurane shown faster elimination after long-lasting anaesthesia than Isoflurane.

A.96 Recovery from anaesthesia with sevoflurane in comparison with isoflurane in elderly patients

S E Gaßmayr, R L Moser, H. Voit, W. Kroll, W.F. List. *Dept. of Anesthesiology & Intensive Care Medicine Karl-Franzens University, Graz, Austria*

Background and Goal of the Study: From a practical point of view the applicability of sevoflurane in geriatric anesthesia is established. However there are only few data concerning the comparison of sevoflurane with other inhalation anesthetics in this group of age (1, 2, 3) The aim of our study was to evaluate to what extent the recovery from anesthesia with sevoflurane (SEVO) or isoflurane (ISO) differs from each other in elderly patients

Material and Methods: After approval of the study by the institutional review board and after written informed consent has been obtained 50 patients ≥65 years (ASA I–III) scheduled for elective surgery were randomly assigned to receive either SEVO (n = 25) or ISO (n = 25) as inhalation agents for maintenance of anesthesia (1 MAC in N_2O/O_2) Induction of anesthesia was performed with sufentanil (25 μg) and thiopentone (2–4 mg/kg), muscle relaxation with atracurium (0 6 mg/kg). If needed sufentanil (10–20 μg) and atracurium (0.3 mg/kg) were supplemented during maintenance period. The time of recovery events (extubation, emergence, response to commands, orientation, first postoperative analgesia, eligibility for discharge of recovery area) was measured.

Results: There are no statistically significant differences between the two groups, however mean times show a positive trend for SEVO· extubation (9.6 ± 4 84 min vs. 12.2 ± 11 36 min), emergence (9.0 ± 4 84 min vs 10.2 ± 6.16 min), response to commands (11.3 ± 5 71 min vs 13.0 ± 8 21 min), orientation (16.6 ± 7 84 min vs 24.7 ± 30.55 min), eligibility for discharge of recovery area (124 ± 31 39 min vs. 130 ± 35.8 min) The first postoperative analgesic in the SEVO group is administered after 50 3 ± 21.33 min compared to 48.3 ± 23.08 min after ISO.

Conclusion: The recovery period of sevoflurane in elderly patients is comparable to that of ISO with a trend to a faster recovery with SEVO and a later requirement of the first postoperative analgesic after anesthesia with SEVO.

A.97 Relationship between time of exposure to desflurane, sevoflurane or isoflurane and recovery times in surgical patients

P. Rama, N Molins, A. Pensado, H. Aymerich, C. Fernández-Goti, C Rodríguez-Valdés *Department of Anaesthesia, Hospital Juan Canalejo, La Coruña, Spain*

Background & Goal of Study: Desflurane (DES) and Sevoflurane (SEV) shown lower solubility, lower accumulation in fat tissues and faster emergence times after anaesthesia than other inhaled anaesthetics The aim of this study was to compare the relationship between time of exposure to DES, SEV or isoflurane (ISO) and recovery times in surgical patients.

Material & Methods: In sixty-seven patients ASA 1, 2, 3 anaesthethic induction was performed with thiopental, fentanyl and vecuronium After orotracheal intubation the patient's lungs were ventilated with 60% N_2O in oxygen (6 lpm fresh gas flow) The patients were randomly assigned to group DES (n = 23), SEV (n = 22) or ISO (n = 22) for maintenance of anaesthesia and anaesthetic concentration was adjusted to mantain arterial pressure and heart rate within 20% of baseline value Age, gender, ASA, fentanyl dose, duration of anaesthesia (Danaes) and MAC-hours were recorded. At the end of surgery anaesthetics were discontinued, final end tidal anaesthetic concentration ($EtAC_f$), expressed in MAC were recorded and fresh gas flow was mantained with oxygen 100%. Danaes , MAC-hours and $EtAC_f$ were plotted against time to eye opening, extubation and orientation Fisher exact test and Pearson test for bivariate correlation were used for statistical analysis. Data are expressed as mean ± SD and $p < 0.05$ was considered significant.

Results: There were no diferences betwen groups in patients age, gender, ASA, total dose of fentanyl, anaesthesia duration, MAC-hours and $EtAC_f$ Emergence times were correlated with $EtAC_f$ but not with MAC-hours for DES group Emergence times were correlated with MAC-hours but not with $EtAC_f$ for ISO group. There were correlation between emergence times with MAC-hours and with $EtAC_f$ for SEV group. Recovery times were not correlated with Danaes in any group (table)

Table (values expressing lineal regression "r" for each par)

	DES group			SEV group			ISO group		
	MAC-h	EtACf	Danae	MAC-h	EtACf	Danae	MAC-h	EtACf	Danae
Eyes	−0 02	0 63*	−0 41	0 50*	0 61*	0 37	0 63*	0 63*	0 33
Extub	0.11	0 44*	−0 25	0 63*	0 51*	0 62*	0 10	0 11	0 09
Orient	0 15	0 57*	−0 43	0.36	0 31	0 27	0 50*	0 40	0 25

*p < 0 05

Conclusión: In our experience, emergence times for DES and SEV showed correlation with $ETAC_f$ however emergence times for ISO showed better correlation with MAC-hours Recovery times were not correlated with the duration of anaesthesia in any group

A.98 Emesis and headache after (MAC) in N_2O of halothane, enflurane and isoflurane: outcome following ENT and eye surgery

A A. van den Berg[1], N.M Honjol, C R Rozano, T Mphanza, A. Rizk, B. Udom. *Anaesthesia Depts., [1]King Khaled Eye Specialist Hospital and Military Hospital, Riyadh 11159, Saudi Arabia*

Introduction: Isoflurane (I) has superseded halothane (H) and enflurane (E) in usage [1, 2] Emesis and headache may follow general anaesthesia. A literature search revealed no data on the effects on emesis and headache of H, E and I, given for balanced inhalational general anaesthesia.

Methods: With Hospital Ethics Committee approval and patient consent, 556 suitable ENT and eye patients were randomised to receive [MAC] in N_2O of H, E or I. Anaesthesia was strictly standardised except that ENT patients received morphine and eye patients fentanyl as analgesic Postoperatively 'blinded' nurses recorded details of emesis, headache, antiemetic and analgesic requirements Analysis used ANOVA, Chi^2, Students 't' and Mann Whitney 'u' tests ($p < 0\ 05$ significance) Samples >150 per group are required to detect a 10% difference, (95% CI, 80% power).

Results: The 3 study groups were comparable, and comprised comparable subgroups having ear, nose, throat, intraocular or non-intraocular surgery. In the PACU, emesis and drug requirements were similar Thereafter, I induced less emesis than H ($p < 0\ 025$) and necessitated less antiemesis than H or E ($p < 0.005$ both comparisons) Headache and analgesic requirements were similar

	H	E	I
Numbers (M F)	188 (114 72)	186 (114 72)	184 (111.73)
Age (years)	27 (14)	27 (15)	24 (14)
Weight (kg)	51 (21)	48 (20)	48 (18)
Surgical time (min)	59 (29)	54 (24)	55 (27)
Emesis	84 (46%)	76 (41%)	66 (36%)*
Antiemesis	42 (23%)	43 (23%)	21 (12%)**
Headache	65 (36%)	66 (36%)	57 (32%)
Analgesia	132 (72%)	140 (76%)	28 (71%)

Data give as mean (SD) (*I < H, **I < H and E)

Conclusion: Emesis and headache are unpleasant, and the former hazardous, following surgery. Isofluranes favourable pharmacological profile [3] and lesser emetic potential (demonstrated here) endorses its use pending outcome comparisons with sevoflurane and desflurane.

A.99 Sevoflurane and propofol in surgical patients: comparison of emergence time and psychomotor function

A Pensado, P Rama, N. Molins, M L Dávila, S Rodiño, M Fraga
Department of Anaesthesia, Hospital Juan Canalejo, La Coruña, Spain

Background & Goal of Study: The aim of the study was to compare the recovery after sevoflurane (SEV) or propofol (PRO) anaesthesia in intermediate duration surgical procedures

Material & Methods: Thirty patients ASA 1, 2, 3 were enrolled in the study Anaesthetic induction was achieved with thiopental, fentanyl (1–1 5 $\mu g\ kg^{-1}$) and vecuronium The patients were randomly assigned to group SEV (n = 18) or PRO (n = 12) for maintenance of anaesthesia supplemented by 60% N_2O in oxygen (6 lpm fresh gas flow). Fentanyl (1 $\mu g\ kg^{-1}$) was administered before surgical stimulation and anaesthetic concentration was adjusted to mantain arterial pressure and heart rate within 20% of baseline value Age, gender, ASA, fentanyl dose, anaesthesia duration, MAC-hours of SEV and total dose of PRO were recorded. At the end of surgery, anaesthetics were discontinued and fresh gas flow was mantained with oxygen 100% The times to eye opening, spontaneous ventilation, extubation and orientation were recordered A Newman test[1] was performed the day before surgery and at arrival, 20, 40, 60, 90 and 120 min at the PACU Postoperative (PO) nausea and vomiting and the dose of morphine sulfate needed (PCA administration) in 24 hours were recorded Fisher exact test and Student *t* test were used for statistical analysis Data are expressed as mean ± SD and $p < 0\ 05$ was considered significant

Results: There were no diferences betwen groups in patients age, gender, ASA, total dose of fentanyl, anaesthesia duration, PO nausea and/or vomiting, dose of morphine sulphate and Newman's test scores Eye opening time was shorter for SEV group (table)

Table

	Ventilation (min)	Eye open (min)	Extubation (min)	Orientation (min)
SEV	5 0 ± 2 4	7 0 ± 3 5[a]	6 9 ± 3 1	12 5 ± 5 9
PRO	7 3 ± 4 5	11 5 ± 4 8	9 4 ± 4 1	17 5 ± 8 5

[a]p < 0 05

Conclusion: In our experience, the patients who received Sevoflurane only shown faster eye opening after anaesthesia than those who received Propofol. There were no diferences in sensorymotor recovery, side effects or in PO analgesic requeriments in both groups

A.100 Cognitive recovery after carotid endarterectomy: a comparison of isoflurane *vs* desflurane or sevoflurane anaesthesia

V. Umbrain, J Keens, J D'Haese, E De Roover, F Camu *Free Flemish University of Brussels Medical Center, Dept. of Anaesthesiology, Brussels, Belgium*

Introduction: Improved physical properties leading to faster post-operative neurological assessment could make the new inhalational agents desflurane and sevoflurane suitable agents for anesthesia of high risk patients for carotid endarterectomy (CE) In this open label randomized clinical trial, we investigated different post-operative recovery characteristics after CE in patients anaesthetised with either isoflurane, sevoflurane or desflurane

Methods: The protocol was approved by the University Ethics Committee and 75 patients gave informed consent. Anesthesia was induced with propofol 1 mg/kg, alfentanil 15 $\mu g/kg$ and vecuronium 0 08 mg/kg and maintained with equipotent isoflurane, sevoflurane or desflurane concentrations (0.5–1.5 MAC) in 40% of oxygen/air. Surgical and neurological adverse effects were recorded. Postoperative extubation times and times

Time (min) to Communication	Extubation	Conscious Movement	Oral
Isoflurane	13 0 ± 0 8	20 8 ± 0 9	29 8 ± 1 4
Sevoflurane	9 9 ± 0 7	14 0 ± 1 0	20 9 ± 1 5
Desflurane	7 6 ± 0 9	10 4 ± 1 0	16 0 ± 1 4
P-values			
Iso vs Des	**	**	**
Iso vs Sevo	*	**	**
Des vs Sevo	NS	*	*

(** = P < 0 001, * = P < 0 05)

to move consciously controlateral limb and to oral communication were compared Data were expressed a mean ± SE and analysed with ANOVA and paired t-tests P < 0.05 was considered as significant

Results: The three groups (n = 75) had similar demographic variables Duration of surgery and clamping times of the carotid artery were comparable (see table).

Conclusion: Desflurane and sevoflurane provide faster neurological assessment than isoflurane after carotid endarterectomy Recovery times were even shorter with desflurane than with sevoflurane This fast cognitive recovery allows more adequate detection of immediate postoperative complications as neurologic deficits or retrosternal pain.

A.101 Quality and time of recovery from longlasting desflurane or isoflurane anaesthesia

A Pensado, P. Rama, N. Molins, A. Figuelra, J Muñiz *Department of Anaesthesia, Hospital Juan Canalejo, La Coruña, Spain*

Background & Goal of Study: Desflurane (DES) is associated with a fast recovery in short duration anaesthesia when compared with other more soluble agents. However is in long-lasting anaesthesia where its properties can be more useful[1]. The aim of this study was to compare the recovery after DES or Isoflurane (ISO) anaesthesia in long-lasting open urological procedures

Material & Methods: In forty-four patients ASA 1, 2, 3 anaesthethic induction was performed with thiopental, fentanyl (1–1.5 $\mu g.kg^{-1}$) and vecuronium. After orotracheal intubation the patient's lungs were ventilated with 60% N_2O in oxygen (6 lpm fresh gas flow) The patients were randomly assigned to group DES (n = 23) or ISO (n = 21) for maintenance of anaesthesia. Fentanyl (1 $\mu g\ kg^{-1}$) was administered before surgical stimulation and anaesthetic concentration was adjusted to mantain arterial pressure and heart rate within 20% of baseline value. Age, gender, ASA, fentanyl dose, anaesthesia duration and MAC-hours were recorded At the end of surgery anaesthetic were discontinued and fresh gas flow was mantained with oxygen 100%. The times to eye opening, spontaneous ventilation, extubation and orientation were recordered. A Newman test[2] was performed the day before surgery and at arrival, 20, 40, 60, 90 and 120 min at the PACU. Postoperative (PO) nausea and vomiting and the dose of morphine sulfate needed (PCA administration) in 24 hours were recorded. Fisher exact test and Student *t* test were used for statistical analysis. Data are expressed as mean ± SD and p < 0.05 was considered significant.

Results: There were no diferences betwen groups in patients age, gender, ASA, total dose of fentanyl, anaesthesia duration, MAC-hours, PO nausea and/or vomiting and the dose of morphine sulphate. Recovery times were shorter for DES group, (table). Newman's test scores were better for DES group only at min 120.

Table

	Ventilation (min)	Eye opening (min)	Extubation (min)	Orientation (min)
DES	5 0 ± 2 1[b]	7 7 ± 3.8[a]	7 9 ± 3 0[a]	12 9 ± 5.0[c]
ISO	7 4 ± 3.2	12.0 ± 4 6	11.0 ± 3 6	18 0 ± 7 3

[a]p < 0 005 [b]p < 0 01 [c]p < 0 05

Conclusión: In our experience, the patients who received Desflurane shown faster recovery from anaesthesia than those who received Isoflurane. There were no diferences in side effects or in PO analgesic requeriments in both groups.

A.102 Sevoflurane is comparable to propofol for the insertion of laryngeal mask airway in adults

Lian Kah Ti, Mark Yew Hoong Chow. *Department of Anaesthesia, National University Hospital, 5 Lower Kent Ridge Road, 119074, Singapore*

Background & Goal of Study: The high concentration of sevoflurane used during the rapid inhalational induction of anaesthesia with the single vital capacity breath technique allows the rapid insertion of the laryngeal mask airway (LMA) [1]. This study compares the reliability, quality, and speed of LMA insertion in adult patients anaesthetised with either sevoflurane or propofol

Materials & Methods: 64 unpremedicated ASA I-II patients, aged 18–40, undergoing elective surgery were randomly divided into 2 groups. Patients in the sevoflurane group (n = 34) were instructed to exhale to residual capacity. A facemask connected to a circle/absorber circuit primed for 1 minute with 8% sevoflurane in 66% nitrous oxide (N2O) was then placed and the patients instructed to take a vital capacity breath and hold it as long as possible. 90 seconds later, the jaw of the patient was assessed for degree of relaxation, and if the mouth opening was easy, LMA insertion was attempted. If the jaw relaxation was inadequate, the patient continued breathing spontaneously 8% sevoflurane in 66% N2O Reattempts were made every 30–60 sec for a maximum of 4 times. Patients in the propofol group (n = 30) received iv propofol 3 mg/kg Assessment of jaw relaxation followed by attempted LMA insertion was carried out 60 sec later. Reattempts are made up to 4 times every 30–60 seconds, preceded each time by iv propofol boluses of 0 5 mg/kg.

Results and Discussion: The 2 groups were comparable in age, sex, and weight Anaesthesia was successfully induced in all patients All failures of insertion of the LMA were due to inadequate jaw relaxation

	Sevo	Propofol	
Time to LOC (s)	41 (14)	38 (9)	NS
Successful LMA insertion (%)	100	86 7	NS
Time to LMA insertion (s)	128 (36)	71 (19)	NS
Gag/cough (%)	14 7	28.5	NS
Involuntary movement (%)	17 6	44 8	#
Fall in mean BP %	23 2	24 7	
Pleasant induction (%)	91 1	93 1	NS

#P < 0 05 () denotes SD

Conclusion: Sevoflurane provides a rapid, reliable, acceptable, and haemodynamically stable alternative to propofol for the insertion of the LMA in adults.

A.103 PCCO monitoring during major surgery

G. Della Rocca, C Montecchi, C. Coccia, F. Pugliese, L Pompei,
F Ruberto, F. Musolino, P Di Marco, A Gasparetto. *University of Rome "La Sapienza", Istituto di Anestesia e Rianimazione, Italy*

Introduction: The pulse contour (PCCO) method gives continuous cardiac output values by an arterial pressure wave analysis calibrated with a simple arterial thermodilution measurement. All hemodynamic parameters are monitored through an arterial access and a central venous catheter, without pulmonary catheter, with a lower invasiveness. We compared the cardiac output (CO) obtained from a traditional pulmonary catheter (TD) to the CO obtained with PCCO.

Methods: 20 pts scheduled for lung transplantation (10), liver transplantation (2), general major surgery (4) and thoracic surgery (4) were studied For each patient we analyzed CO in three phases. before surgery (A), during the surgery (B) and at the end of surgery (C). We correlated CO obtained from Swan Ganz catheter and from PCCO catheter (SPSS Plus, PC).

Results: We didn't find significant difference between these two techniques (R = 0.91; R_2 = 0 83) In the following Table values obtained from PCCO and TD in four different surgical procedures, during three phases (A; B; C), are reported

	Lung Tx (10 pts)			Liver Tx (2 pts)		
Phases	A	B	C	A	B	C
PCCO (L/min)	5 4 ± 1 3	5.4 ± 0 7	6 4 ± 1 1	5 4 ± 2 4	3 6 ± 1 0	7 5 ± 0 4
TD (L/min)	4.9 ± 1 4	5 5 ± 0 4	5.8 ± 1 1	5 6 ± 2 1	4 0 ± 1 1	8 6 ± 0 7

	General Major Surgery (4 pts)			Thoracic Surgery (4 pts)		
Phases	A	B	C	A	B	C
PCCO (L/min)	3.6 ± 0 7	7 6 ± 2 6	6 0 ± 2 3	5 1 ± 2 2	6 9 ± 2 4	6 9 ± 2 5
TD (L/min)	4 4 ± 1.8	6 9 ± 4.4	5 5 ± 1 6	5 3 ± 2.0	7 2 ± 2 5	6 9 ± 2 8

Discussion: PCCO through an arterial catheter and a central venous line is able to detect with high correlation CO if compared with standard TD technique, as confirmed by our results.

Conclusions: Pulsion PICCO is an innovative monitoring system that is less invasive than traditional pulmonary artery catheter for thermodilution, is easy to use and safe The results of our study confirm the validity of PCCO and it can be used as a routine monitoring for major surgery.

A.104 Evaluation of PCCO during lung transplantation

G. Del Rocca, C. Montecchi, C. Coccia, F. Pugliese, L Pompei,
F. Ruberto, M.G. Costa, M Antonini, A Gasparetto *University of Rome "La Sapienza", Istituto di Anestesia e Rianimazione, Italy*

Introduction: Pulsion PICCO is a new monitor, which measures hemodynamic parameters by a beat to beat analysis of the arterial pressure wave calibrated with a simple arterial thermodilution measurement. Using only a central venous catheter and an arterial access is less invasive than the traditional method, which uses a pulmonary arterial catheter. The aim of this study is to compare conventional technique of cardiac output (CO) using a Swan-Ganz catheter (TD) to the measurements obtained with Pulsion PiCCO in pts undergone bilateral sequential single lung transplantation (BSSLTx).

Methods: 10 patients were studied All patients were monitored with a Swan-Ganz catheter and a femoral artery catheter We evaluated CO in six different phases before induction of anaesthesia (A), during the first lung implantation (B), after the reperfusion of the first lung (C), during the implantation of second lung (D), after the reperfusion of second lung (E) and (F) final at the end of the surgery We correlated all CO values obtained from the PCCO and pulmonary artery catheter respectively in all the evaluations for each pt (SPSS Plus, PC)

Results: We didn't find a significant difference between the values obtained from these two different monitors ($R = 0\ 92$; $R^2 = 0\ 84$) In the following Table CO values evaluated with PCCO and TD in five different phases during BSSTx is reported.

Phases	A	B	C	D	E	F
PCCO (L/min)	5 4 ± 1 3	6 6 ± 2.3	6.8 ± 1 7	5 4 ± 0 7	6 4 ± 1 0	6 4 ± 1 1
TD (L/min)	4 9 ± 1 4	6 1 ± 1 7	7 8 ± 2 4	5 5 ± 0 4	6 3 ± 1 0	5 8 ± 1 1

Discussion: PCCO is a new monitor that only after the initial calibration provides continuos CO measurement, it's easy to use, safe and less invasive than Swan-Ganz catheter with a high correlation, as confirmed by our results, even if used in major surgery like BSSTx, in which you can have several artefacts because of surgical heart manipulations.

Conclusions: It will may be use as routine monitoring in alternative to pulmonary arterial thermodilution, even if further clinical evaluations are necessary to confirm our preliminary results.

A.105 Continuous cardiac output: agreement with bolus thermodilution method

J.G Martín Hernández, T. Carnero Carnero, M.M Orts Rodriguez, C Pérez Hernández, J Lorenzana, F Gilsanz. *Hospital Universitario de La Princesa, Diego de León 62, 28080 Madrid, Spain*

Introduction: Several different approaches for continuous cardiac output monitoring have been developed in recent years Continuous cardiac output (CCO) monitoring system are based on the pulsed warm thermodilution technique Using the same equipment, traditional standard intermittent bolus cardiac output (ICO) values may be obtained by conventional algorithms. The aim of this study was to evaluate the correlation between standard ICO and CCO measurement in patients undergoing coronary artery by pass surgery.

Material and Methods: 15 consecutive patients undergoing coronary revascularization with a hipothermic low-flow, low-pressure cardiopulmonary bypass (CPB) technique were studied. All patients received a conventional narcotic-based anesthetic technique including high-dose fentanyl, midazolam and pancuronium bromide. Cardiac output measurements were accomplished baseline, post-anaesthetic induction, poststernotomy and 15 minutes after the exit of the CBP. CCO was determined immediately before and after ICO measurements, and the average of these two values was recorded as CCO.

Statistical analysis was performed using linear regression for the data pairs, Pearson's correlation coeficient, analysis of agreement to assess bias and distribution of observed differences between techniques according Bland and Altman study.

Results: A total of 60 data pairs were obtained. ICO ranged from 2 to 9.6 L/min, CCO from 2 to 9.2 L/min. The linear regression is represented by: CCO = 0.38 × ICO + 0.71.

Correlation between ICO and CCO was $r = 0\ 71$ ($p < 0.01$). The absolute measure bias was 1.28 L/min with 95% confidence limits ± 2.19 L/min

Discussion: This study has shown a certain discrepancy between the two measure methods of cardiac output These results are in agreement with Siegel[1] and Lefrant studies and in contradiction with those of Yedelman, Boldt[2] and Jakobsen[3]. Consequently, the CCO in comparison with ICO can be a responsible measure of cardiac output More studies would necessary to confirm the clinical interest and to define their indications

A.106 Clinical implications of continuous automated thermal cardiac output measurement in abdominal aortic surgery

B. Grosomanidis, N Tsotsolis, E Papanastasiou, D. Setzis, A Efthimiou, C. Skourtis. *Department of Anaesthesia and I.C U, 'AHEPA' G H., Thessaloniki, 54636, Greece*

Introduction: The optimal anaesthetic management of the patient undergoing abdominal aortic surgery remains a major challenge Limited myocardial reserve in most of the cases, due to coexisting coronary disease, in conjuction with the supervening haemodynamic changes resulting from the aortic clamping and unclamping, impose a puzzling problem Selection of the proper monitoring remains a matter of controversy despite recent advances in the field We undertook this study in order to evaluate the efficacy and usefullness of an automated continuous cardiac output pulmonary artery catheter in the intraoperative management of the aforementioned operations.

Material and Methods: Twenty-one patients undergoing scheduled abdominal aortic surgery for atherosclerotic stenosis or aneurysm (7 and 14 respectively) were included to our study All of them had coronary artery disease (CAD) and hypertension under chronic medication, their ASA Physical Status was 3–4 and their age between 47 to 76 years old Premedication consisted of 0.1 mg/kg b w morphine given IM 1 hour preoperatively Pulmonary artery catheterization was performed using a continuous thermal cardiac output catheter that measures also the oxygen saturation of the mixed venous blood (OPTI-Q, Abbott Lab); an arterial line, peripheral pulse oxymetry, electrocardioscopy and end-tidal CO2 were included to the patients monitoring as a standard Heart rate (HR), systemic arterial pressures (SAP, systolic, diastolic), pulmonary arterial pressures (PAP, systolic, diastolic), right atrial pressure (RAP), continuous cardiac output (CCO) and mixed venous saturation (SvO2) were measured on line. Right ventricular end diastolic pressure (RVEDP), pulmonary capillary wedge pressure PCWP) and derived haemodynamic parameters {stroke volume (SV) and stroke index (SI), vascular resistances (SVR, PVR)} were obtained before induction of anaesthesia, after completion of induction, before surgical incision, before and after completion of preparation of the abdominal aorta, after clamping and every 5 minutes till the unclamping of the aorta, immediately after this event and then every 5 minutes Complete haemodynamic profiles were taken in every unexpected event, too Anaesthesia was induced with midazolam (0.18 ± 0 05 mg/kg b w.) and fentanyl (0 010 ± 0 004), muscle relaxation was achieved with vecuronium, and isoflurane plus fentanyl were used for maintenance of anaesthesia. Vasoactive and inotropic agents were used when a greater than 20% change had occurred in one of the haemodynamic parameters or a tendency towards unfavorable haemodynamic profile had been anticipated

Results: A total of 379 sets of measurements were performed, and 315 of them were part of the aforementioned protocol routine, the remaining 64 were dictated by clinical events and criteria other than those included in our protocol, and in 32 of them (50%) the only haemodynamic parameter that showed an alarming decrease (>20%) was the cardiac output without any other sign of haemodynamic deterioration. Only in one case, with a sudden blood loss of about 600 ml, the SvO2 drop preceded the CO decrease The CO decrease in 4 cases preceded an increase of the RVEDP (from 6 ± 2 to 12 ± 3 mmHg) with a latent time of about 45 seconds (45 ± 12 sec)

Conclusions: The use of an automated continuous thermal cardiac output catheter, under the conditions of our study, enables the anaesthesiologist, dealing with major abdominal aortic surgery, to detect decreases in cardiac output that might otherwise go unnoticed since they are not accompanied by any other haemodynamic changes.

A.107 Continuous *vs* intermittent thermodilution cardiac output after cardiopulmonary bypass

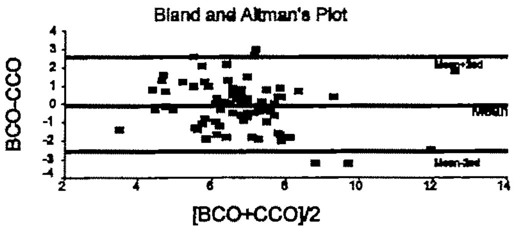
A Mallick, B Barry[1], M. Vucevic[1], A R Bodenham[1] *Royal Hallamshire Hospital, Sheffield, [1] The General Infirmary at Leeds, Leeds, UK*

Background & Goal of Study: Thermodilution techniques using pulsed heat to monitor the cardiac output continuously has been recently introduced into clinical practice. Cardiac output measurement by continuous thermodilution techniques has been shown to have a high level of accuracy and precision in critically ill patients and in cardiac surgery patients (1, 2). Both continuous and conventional bolus techniques may fail to agree in the situations of thermal instability (3). We were intersted to analyse the agreement of cardiac outputs measured by both methods in immediate post-cardiopulmonary bypass period in patients undergoing coronary artery bypass graft surgery.

Materials and Methods: After obtaining infromed consent, 12 patients were enrolled in the study. A pulmonary artery catheter (725H, 7 5 FG, Intellicath™, Baxter Edwards, Irvine, CA) was inserted in the conventional manner after induction of anaesthesia and connected to a cardiac output computer (Vigilance, Baxter Health care Corp., IL). After weaning from cardiopulmonary bypass we performed cardiac output measurements at 10 minutes interval and a total of six measurements was taken in each patient Continuous cardiac output value (CCO) was taken as the mean of 2 stat values performed before and after the sequence of bolus injections Bolus cardiac output (BCO) measurements were performed at end-expiration by manually injecting 10 ml of 5% dextrose at room temperature through Co-set (Baxter) and a mean of three consequtive measurements not varying more than 10% from each other was taken Pulmonary artery temperature was recorded at the measurement points. Rapid volume infusion and diathermy were avoided during the measurement period

Results & Discussion: A total of 96 paired data points were taken. Temperature varied from 35.5 to 37 9°C. Data were analysed by Bland and Altman's bias and precision. The absolute measurement bias was −0.11/min and 95% limits of agreement are at 2.57 to −2 59 l/min. Therefore precision was poor and not acceptable The Bland and Altman's plot is shown below

Bland and Altman's Plot



Conclusion: Continuous and bolus cardiac output measurements have poor agreement in immediate post-cardiopulmonary bypass period in patients undergoing coronary artery bypass graft This may be due to thermal instability and increased thermal noise. Further studies are needed to illustrate which method provides values closest to the real cardiac output of the patient

A.108 Continuous cardiac output and mixed venous oxygen saturation monitoring during cardiac anaesthesia

A Herrera, S. Amezcua, F. Marin, A. Menna, C Suan. *Hospital Universitario Virgen del Rocio Sevilla, Spain*

Background & Goal of the Study: Nowadays, a modified pulmonary artery catheter is available for continuous and simultaneous monitoring of cardiac output by thermodilution (CCO) and mixed venous oxygen saturation (SvO2) by fiberoptic oximetry. The aim of the study is to evaluate the value of the CO obtained by this method and its relation to the SvO2.

Material & Methods: After informed consent, 18 ASA III–IV patients undergoing cardiac surgery under general anaesthesia with controlled ventilation (FiO2 = 0.5) have been studied prospectively. Non-invasive monitoring and invasive blood pressure were established. Following induction of anaesthesia, a modified pulmonary artery catheter 7.5 F (Edward) was inserted via the right internal jugular vein, using an 8 5 F introducer (Abbott). The catheter was connected to the monitoring device (Vigilance, Baxter). Several parameters were measured 15 minutes after induction (M1), 15 minutes before initiating cardiopulmonary bypass (CPB) (M2) and 10 (M3) and 30 minutes (M4) after leaving CPB. In each patient cardiac output was measured at least three times by injecting 10 ml of room temperature normal saline (BCO) and arterial and mixed venous blood samples were obtained in order to measure SvO2(Co) and to calculate derived parameters. Data are presented as mean ± SD and were evaluated using the T Student test, a simple correlation analysis, and tests of bias and precision

Results: There were not statistically significant differences when CI and SvO2 values measured by both methods in all patients (n = 18, 10 CABG and 8 valve replacements) were compared. Significant direct correlation ($p < 0.01$) between CCOI and BCOI (r = 0.86, bias = 0.07 l/m/m2 and precision = 0.75 l/m/m2), between SvO2 and SvO2(Co) (r = 0 87, bias = 0.44% and precision = 4 73%), between SvO2 and CCOI (r = 0 44), and between SvO2 and BCOI (r = 0.35) exists in all measurements (n = 72). The average CCOI and CBOI values stratification (≤ 2, >2, to ≥ 3 5 and >3 5 l/m/m2) shows that increments in the average value improve bias and decrease precision between CCOI and CBOI, and improve bias and increase precision between SvO2 and SvO2(Co) Increments in the haemoglobin value (Hb > 9 g/%) impair bias and increase precision between CCOI and IBCO, and also between SvO2 and SvO2(Co). Decreases in temperature (<36°C) improve bias and decrease precision between CCOI and BCOI but improve bias and increase precision between SvO2 and SvO2(Co). In M1–M4 measurements, there is significant direct correlation ($P < 0$ 01) between CCOI and BCOI, and also between SvO2 and SvO2(Co) with excellent bias and precision ratios. Significant correlation between SvO2 and CCOI, and between SvO2 and BCOI exists in M1, M2 and M4.

Conclusions: During cardiac anaesthesia: 1) Continuous CO and SvO2 monitoring can be considered accurate, 2) CCOI improve bias and decrease precision for higher CI and T values and for lower haemoglobin values 3) SvO2 improve bias and increase precision for lower CI and T values, while lower haemoglobin values impair bias and increase precision, and 4) Significant direct correlation between SvO2 and CCOI, and between SvO2 and CBOI exists in all results and in three of the analysed moments, except 10 minutes after leaving cardiopulmonary bypass (M3)

A.109 Comparing methods of cardiac output measurement: oesophageal Doppler *vs* thermodilution

T. Delgado González, S. García del Valle, S. Gonzáles Fernández, B López López. *Hospital Puerta de Hierro, Madrid, Spain*

Objective: To compare cardiac output (CO) measurements precision and accuracy using an esophageal Doppler transducer (ODM-II, Abbott laboratories) versus pulmonary artery catheter, in a wide range of CO values

Materials and Methods: Patients who were considered suitable to insert a pulmonary artery catheter, were addicionally placed an esophageal Doppler transducer. These techniques were carried out by experienced personnel. All patients were normothermic (35 5°–37.5°C). The average of two CO measurements not differing in more than 10%, was taken as value by thermodilution method. The ODM-II value was taken in a period of stable cardiac rhythm with rate under 100 bpm for 4–5 cardiac bates. Two hundred pairs of CO measurements were taken by means of ODM-II and thermodilution. These pairs of measurements were compared against each other. The statistical tests used were lineal correlation coefficient and Bland–Altman test.

Results: The CO (by thermodilution) range was between 2.6 l/min and 10.8 l/min values The ODM-II – thermodilution differences range was between 1.4 and −1 8 values. The lineal correlation coefficient between CO values by ODM-II and by thermodilution was highly significantly: $R^2 = 0$ 9609 ($y = 0.9258x + 0.6197$). Method (ODM-II) precision was determinated by means of lineal correlation coefficient between ODM-II – thermodilution differences values and thermodilution values The result showed a minimun dispersion of values: $R^2 = 0.1408$ ($y = 0$ $0076x - 0$ 074). Comparison of method accuracy was made using Bland and Altman test: the mean of the differences was 0.29, and the 95% limits of agreement were narrow 1.3.

Conclusions: The esophageal Doppler transducer showed a good precision and accuracy with regard to pulmonary artery catheter Although our findings showed that ODM-II had high precision and accuracy during all cardiac output states, this one underestimated cardiac output during low cardiac output estates.

A.110 Non-invasive haemodynamic monitoring: oesophageal Doppler *vs* thermodilution in cardiac surgery

A. Toral, M J Martín, C Bonome, S Garrido, E. Rodriguez *Department of Anesthesia, Hosp Juan Canalejo, La Coruña, Spain*

Background & Goal of Study: Invasive hemodynamic monitoring is the standard method of measure nowadays the performanceof the cardiovascular system. Pulmonary artery catheterisation has been related with morbidity,: injuries related to central cannulation, pulmonary artery rupture, disrithmias, cardiac blockade asistole and others (1) Futhermore the measurement of cardiac output with thermodilution method provides only intermitent data Transoesophageal doppler ultrasound of descending aortic blood flow, provides an alternative, continuous, noninvasive method of measuring haemodynamic parameters (2, 3)

The purpose of this study was to compare the values of cardiac output (CO) using both methods (thermodilution Vs oesophageal doppler), in cardiac surgery patients.

Material and Methods: 20 patientes underwent cardiac surgery. Haemodynamic registers. **1-Swan Ganz catheter (REF-1, Baxter Lab):** CO, central venous pressure (CVP), pulmonary artery pressure (PAP), Pulmonary wedge pressure (Pw), right end-systolic & end-dyastolic volumes (RESV, RESV), right ejection fraction (REF), right and left systolic ventricular work (RSVW, LSVW), systemic and pulmonary vascular resistances (SVR, PVR). **2-Oesophageal doppler (ODM II, Abbot Lab):** CO, Flow corrected time (FTc), Peak velocity (Pv) and Mean aceleration (Ma) 133 simultaneous registers of those haemodynamic values. Statical analysis: Correlation bivariate, Pearson's test. Significance was acepted for $p < 0$ 05.

Results & Discussion: We have found an excellent correlation on CO values between both methods throughout all study. (CO Doppler 4.65 ± 1.50 lpm Vs CO thermodilution 4.7 ± 1.49 lpm; r2 = 0.839, $p < 0$ 0001). There were a significance correlation between FTc, Pwp ($r = 0.69$, $p < 0.01$), CVP ($r = 0.73$, $p < 0.005$) and SVR ($r = -0.81$; $p < 0.005$).

Conclusions: 1- There was an excellent correlation between both methods respect to CO values 2- FTc is a parameter directly well-correlated with classisc parameters of preload and inversely correlated with afterload.

A.111 Improved safety during labetalol-induced hypotension by using an oesophageal Doppler for continuous monitoring of cardiac output

M Papageorgiou, I. Zevla, A. Dimakopoulou *Hygeia Hospital, Marousi, Athens, Greece*

Background and Goal of Study: The purpose of this study was to employ a non-invasive method to monitor continuously alterations of cardiac output (CO) during the use of Labetalol in neurosurgical procedures to ensure its safety

Materials and Methods: Twenty patients, ASA grade I–II, aged 20–60 received general anaesthesia for neurosurgical operations. Total intravenous anaesthesia was induced with propofol, alfentanyl and atracurium. Mild hypotension was induced by Labelatol in incremental doses of 0 5, 0 75 and 1 0 mg/kg to maintain a mean arterial pressure of 60 ± 7 mmHg for a period of 50 ± 10 minutes Haemodynamic monitoring was obtained by E.C G., direct cannulation for arterial and central venous pressures and an oesophageal probe for continuous CO monitoring (ODM II, Abbott)

Results: The changes associated with the hypotension were a slight reduction of the mean estimated CO by 0.57 L/min (4 77 to 4.20), a reduction of mean peak velocity by 9.4 cm/sec (76.8 to 67.4), a remarkable reduction of mean systemic vascular resistance by 347 4 dyn.sec cm–5 (968.7 to 621.3) and a slowing of mean heart rate by 12 beats/min (73.8 to 61.8).

Conclusion: The oesophageal doppler provides a simple and effective method of continuous haemodynamic monitoring to ensure that Labetalol is used safely to obtain hypotension without clinically significant reduction of cardiac output

A.112 Intraoperative control of the efficiency of thoracic sympathectomy for palmar hyperhidrosis by monitoring width pulse waveform and temperature

M.J Jiménez, G. Fita, I. Rovira, G. Martínez, M A Callejas, X Baldó. *Departament of Anaesthesia, Clínic Hospital, University of Barcelona, Spain*

Background and goal of study: Primary palmar hyperhydrosis is a benign disorder, nevertheless it may disrupt professional and social life. Endoscopic transthoracic sympathectomy (ETS) is now considered the treatment of choice[1, 2], but currently, no accurate method to asses procedure efficiency during the operation, has been described. The aim of the study was to evaluate intraoperative ETS efficiency by monitoring changes in the width of the pulse wave as well as temperature (T°) in the hand on the sympathectomy side

Patients and methods: Sixty patients scheduled for bilateral ETS were prospectively studied All patients were under general anaesthesia, intubated with a left doble lumen endo bronchial tube and one lung ventilation. Patients were monitored with ECG, invasive arterial blood pressure, SpO_2, end-tidal CO_2 T° was monitored continouosly in both, right and left hand, using a skin sensor placed on each thenar prominence. Record of pulsioximeter wave-form, and hands, T° were obtained after anesthesia induction (BASAL), before T2 sympathicotomy (PRE-SYMP), and at 10 and 20 min post-simpathectomy (10′ and 20′ POSTSYM). The record of difference in temperatures between both hands (ΔTEMP °C) at these times, allows us to discard the influence of anaesthetic or environment factors

Results: An increase in the width of pulse wave superior to 5 mm was observed inmediately after T2 sympathicotomy (left and rigth), In 28 cases (87 5% of patients) The average temperature increase was about 3°C post-sympathectomy (see table)

	Basal	Pre-symp	10′ Post-symp	20′ Post-symp.
TEMP R °C	30 68 ± 2 9	39 91 ± 2 5	32 60 ± 2 2*	33 64 ± 2.2*
TEMP L °C	29 1 ± 2 8	29 06 ± 3 0	31 45 ± 3 8*	32 56 ± 2 2*
ΔTEMP °C Rigth symp	1 58 ± 2 1	1 62 ± 2 4	3 33 ± 2 6*	4 36 ± 2 7*

Mean (± SD) *p ≤ 0 01 Paired student's t-test

Conclusions: Monitoring the width of the pulse wave-form and temperatures is a simple and valid method to control the efficiency of the sympathectomy, since it reflects vasodilation.

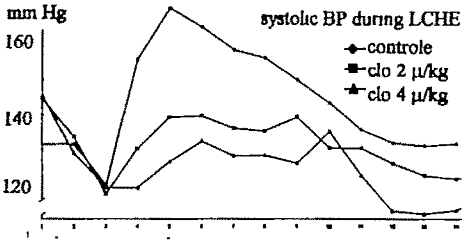
A.113 Premedication with clonidine for laparoscopic cholecystectomy

J. Málek, J Knor, A. Kurzová, M. Lopourová. *Dept of Anaesth , 3rd Med School, Charles University, Prague, Czech Republic*

Background and Goals of the Study: Adverse haemodynamic reactions to capnopentoneum during laparoscopic cholecystectomies (LCHE) have been reported The purpose of the study is to demonstrate the effectiveness of a clonidine in prevention of these reactions.

Materials and Methods: After an approval 63 patients elicited for LCHE were randomly allocated into three equal groups. control g. (C) withouth clonidine, and two gps. with clonidine 2 μ/kg (Clo2) and 4 μ/kg (Clo4) resp administered in 100 ml infusion 10 min before induction of general anaesthesia (GA) GA in all groups was performed in a standard way Blood pressure (BP), pulse (P), SaO2 and ETCO2 were measured regularly and at specific phases of surgery (see graph) 1-before clonidine, 2-after clonidine, 3-after induction, 4-beginning of CO2 insuflation (Ins), 5-antiTrendelenburg position (aT.), 6, 7, 8-5 min, resp. 15 min, 30 min after aT, 9-desuflation, 10 end of surgery, 11, 12, 13, 14-1/2, resp 1, 2 and 4 h. after surg The results were tested by Anova Test

Results: There were highly statistically significant differences in systolic BP, MAP, and lower differences in diastolic BP between both clonidine groups and C There was no stastistical difference between Clo2 and Clo4 in suppression of hypertension, but there was higher incidence of bradycardia in Clo4 Less consumption of fentanyl in both Clo groups has been found.



Discussion and Conclusions: Clonidine is an effective agent to prevent adverse sympathetic reaction during LCHE. In spite of some references we did not find beneficial effect of higher doses, on contrary we saw higher incidence of side effects, mainly bradycardia and sedation. We conclude, that i v. clonidine suppresses hypertensive reaction to capnopentoneum in LCHE, the dose 2 μ/kg offers more advanteges than 4 μ/kg Next studies with i m and p.o. clonidine are prepared

The study was supported by IGA MZ ČR, 4142-2

A.114 Effects of age and gender on the optimal administration dose of intramuscular midazolam premedication

T Nishiyama, K Hanaoka *Department of Anesthesiology, The University of Tokyo, Tokyo, Japan*

Background and Goal of Study: There are lots of studies about the effects of intramuscular (i.m) midazolam as a premedication However, there are large differences among the studies in the dose and the time of administration. Surprisingly no detailed studies are seen about the optimal dose of i.m. midazolam considering both age and gender. The purpose of this study was to look for the optimal dose of i.m midazolam as a premedication in different age and gender.

Materials and Methods: After the approval by our institutional review board and written informed consent, each 100 males and females in 20 to 39, 40 to 59, and 60 to 79 years (totally 600 patients) were randomly divided into 5 groups according to the midazolam dosage, 0 04, 0.06, 0.08, 0 10, and 0.12 mg/kg Midazolam was injected i m. with atropine 0 01 mg/kg (maximum 0 5 mg) 15 minutes before the induction of anesthesia Blood pressure (BP), heart rate, respiratory rate, percutaneous arterial oxygen saturation (SpO_2), sedation level, existence of the tongue root depression, and eyelash reflex were monitored before and 15 minute after (before anesthesia induction) premedication In addition, anterograde amnesia was checked. Two way factorial analysis of variance followed by Scheffe's F test, Kruskal-Wallis test, and chi-square test were used for statistical analysis P < 0.05 was considered to be significant.

Results and Discussion: Regarding the time of administration, to avoid patients to get the peak effect before enterng the operating room, midazolam was administered 15 minutes before the induction of anesthesia according to our previous study[1]. There were no significant differences between male and female in any parameters in any age. This matched the pharmacological data that showed the difference in only plasma clearance of midazolam, which can not affect acute dose requirements like premedication[2]. Sedation level and amnesia increased according to the increase of age and midazolam dose. Decrease of SpO_2 and loss of eyelash reflex were seen with midazolam 0 10 mg/kg or more in 20 to 39 years, and with 0.08 mg/kg or more in 40 to 59 years In 60 to 79 years, decrease of BP and SpO_2, loss of eyelash reflex, and depression of the tongue root were observed with midazolam 0.06 mg/kg or more Taking side effects into consideration, these doses might be dangerous in some patients

Conclusions: The optimal dose of intramuscular midazolam 15 minutes before anesthesia induction was 0 08, 0 06 and 0 04 mg/kg for 20 to 39, 40 to 59, and 60 to 79 years, respectively, without any differences between male and female

A.115 Effect of midazolam premedication on implicit memory activation during alfentanil-nitrous oxide-halothane anaesthesia

F Ulus, G. Ozmert, N. Kadıoğulları *Dept of Anaesthesiology, Ankara Oncology Hospital, Ankara, Turkey*

Background: Experiences of awareness and recall during general anesthesia can be most distressing for patients. To obtain relevant information, the authors systematically interviewed patients in whom awareness during surgery had occurred and questioned them about their experiences.

Material and Methods: Hundred consenting patients were assigned to two equal groups, to receive 0.08 mg kg^{-1} intramuscular midazolam or normal saline as premedication before general anesthesia with alfentanil-nitrous oxide-halothane During anesthesia, tape containing the test material was played to each patient on a portable cassette player. In the postanesthesia care unit and 24 h after surgery, patients were evaluated using standard questions

Results and Discussion: None of the patients had any recall of events during surgery in midazolam group but one patient in control group was able to recall tape material and another one had experienced nightmare.

Conclusion: We have shown that midazolam 0.08 mg.kg^{-1} given intramuscularly 30 min before anaesthesia prevents activation of implicit memory during alfentanil-nitrous oxide-halothane anaesthesia Since suppression of implicit memory by alfentanil-nitrous oxide-halothane alone cannot be guarenteed we recommend that alfentanil-nitrous oxide-halothane anaesthesia be routinely supplemented with midazolam.

A.116 Awareness during anaesthesia in patients undergoing cardiac surgery

L Qvist, L Algotsson *Department of Anaesthesiology and Intensive Care Medicine, University hospital, S-221 85 Lund, Sweden*

Background: The incidence of awareness with recall during general anaesthesia has been reported to be 0.2% (1). In patients undergoing cardiac surgery the incidence seems to be higher. Figures between 1 to 23% have been reported (2) No long-term follow up has been presented in any of these studies The purpose of the present study was to examine the incidence of awareness with recall in anaesthesia during cardiac surgery after four days and three months post surgery

Materials and Methods: After approval from the local ethic committee, one hundred ASA III patients, scheduled for elective cardiac surgery with cardiopulmonary bypass (CPB), gave informed consent to participate in the study. The mean age was 61 years; range 35–79. Premedication was standardised. A balanced anaesthetic technique consisting of midazolam (0.5 ± 0.2 μg/kg/min, mean ± sd) and fentanyl (0 1 ± 0.02 μg/kg/min) was employed. 50% N_2O was added to the O_2/air gas mixture before CPB. Patients were randomised either to isoflurane (0 5–1.5% end-tidal concentration) or propofol infusion (49 ± 19 μg/kg/min) as anaesthetic maintenance during and after CPB. During CPB isoflurane was added direct into the cardiopulmonary bypass system The patients lungs were mechanically ventilated. No muscle relaxant were administered after induction of anaesthesia. Invasive blood pressure, heart rate, body temperature as measured in the urinary bladder, blood glucose, and arterial and venous blood gases were recorded. CPB was performed during hypothermia (30–32 oC) and mixed venous oxygen saturation were kept above 70% Every patient were interviewed four days and three months after surgery and were asked the same questions at both occasions by the same interviewer.

Results: Three out of 100 patients reported awareness with recall after four days. After three months five patients reported awareness. Only one patient out of three with early awareness reported awareness after three months. Interestingly four out of five patients with late awareness were randomised to isoflurane as anaesthetic maintenance as compared to one in the propofol group. However, the difference did not reach statistic significance

Conclusion: Awareness seems to be a problem during cardiac surgery. Adequate concentrations of inhaled or intravenously administered anaesthetics do not prevent awareness and recall completely

A.117 Need for oxygen supply for patients' transfer from the surgical room to the post-anaesthesia care unit

T. Saz, G. Aguilar, J Soliveres, C. Reina, J V Llau, F J. Belda *Anaesthesia and Critical Care Dept. Hospital Clínico Universitario, Valencia, Spain*

Background: At immediate post-surgical period, there is a trend to hypoxemia due to residual effects of anesthetic drugs In order to avoid hypoxemia, almost every patient receive supplementary oxygen at his arrival to PACU. The aim of this study was to evaluate the need of oxygen supply during transfer from surgical room to PACU

Methods: After institutional approval, we studied 70 ASA I/II patients without associated pulmonary nor cardiac pathology, undergoing gynecologic, ophtalmologic or traumathologic surgery under general anaesthesia After extubation, supplementary 100% oxygen was administered during at least 3 minutes until peripheral oxygen saturation (SpO_2) was greater than 94% observed by pulsioxymetry. The patient was moved to PACU breathing spontaneously without oxygen supply, with continuous monitoring of SpO_2 Time of transfer was defined as the time comprised from change from surgical position to bed, until the arrival to PACU. Time of transfer and variations in SpO_2 were measured, evaluating changes from the first value (surgical room) to the last one (PACU) Data are expressed as mean ± SD or median and range Data were analized by paired sample student t test or Wilcoxon signed ranks test as appropiate, with $p < 0.05$ considered statistically significant

Results: Mean age of patients was 51 ± 19 years. Time expended in the transfer was 2′ 51″ ± 35″. SpO_2 in the moment of beginning the transfer was 98% (95%–99%), and at the arrival to PACU was 95% (91%–99%) ($p = 0.0001$) 6/70 (8 6%) patients had a SpO_2 smaller than 92% at the arrival to PACU, with a transfer time of 2′ 56″ ± 21″ ($p > 0.05$). No patient had a SpO_2 smaller than 90% at the arrival to PACU.

Conclusions: Oxygen desaturation is quite common during the transfer from surgical room to PACU. ASA I/II patients without associated pulmonary nor cardiac pathology do not need oxygen supply, although there is a statistically sinificative decrease of the SpO_2 The need of oxygen supply during this period of time must be evaluated patient by patient, mainly regarding associated pathology

A.118 Oculocardiac reflex: is it relevant?

Á. Bognár, T. Torok, Z Gingl, A. Kardos, L. Kolozsván, L. Rudas. *Depts. of Ophtalmology and Anesthesiology, Albert Szent- Gyorgyi Medical University, Szeged, Hungary*

Background and Goal of Study: Substantial bradycardia due to the oculocardiac reflex is a feared complication of ophthalmic surgery. Although anecdotal reports often refer to this reaction the convincing evidence of the threatening reaction is scarce.

Materials and Methods: In order to asses the autonomic reactivity reflex, tests were performed in 32 ophthalmic patients (mean age 64 years S.D. 17) awaiting for surgery. No ophthalmic patients had history of cardiovascular disease or syncope. Controlled oculopression (OP) of 80 mmHg for 30 sec was applied to both eyes in succession. Subsequently 10 sec carotid sinus massage (CSM) was performed on both sides. The blood pressure was recorded continuously by a photopletysmograph (Finapress 2300).

The ECG was also recorded. Hemodynamic signals were stored and analysed off-line

Results and Discussion: CSM resulted in significant lengthening of RR intervals (Δ RR 230 ms S.D. 239). This response was contrasted by a much smaller though still significant bradycardia elicited by OP (Δ RR 44 ms S.D. 69) The systolic blood pressure decreased following CSM by 26 mmHg (S.D 17). The OP induced systolic blood pressure drop was only 7 mmHg (S.D 12). According to standard definitions hypersensitive carotid sinus response (HCSR) occurred in 4 patients (12 5%). Systolic blood pressure responses on CSM were predictive of OP responses of similar extent ($p < 0.043$).

Conclusions: OP was associated with moderate hemodynamic responses. It is posssible that the tonic eye compression does not reproduce the stimuli imposed by the traction of the extraocular eye muscles occurring during surgery The manual massage of the eyes might have been more representative of the surgical stimuli, however uncontrolled eye compression is not recommended in this patient population As indicated by our results HCSR is a frequent phenomenon among healthy elderly individuals It has been documented that there is an overlap between the neurally mediated syncopal reactions of different origins. Our results substantiate the relationship between the OP and CSM reactions Therefore we suggest that OP test should be replaced by CSM in preoperative assessment of eye surgery patients. Perioperative monitoring of the hemodynamic parameters of the susceptible subject should be recommended

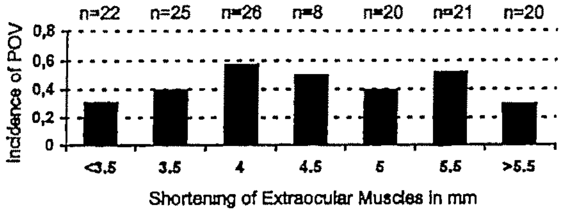
A.119 Is there a correlation between postoperative vomiting and increased extraocular muscle tone in strabismus surgery?

T Papenfuss[1], C C Apfel[1], W.D Schafer[2], P Kranke[1], C. Goepfert[1], P Sefrin[1], N Roewer[1]. [1]*Department of Anaesthesiology,* [2]*Department of Ophthalmology, University of Wuerzburg, Germany*

Background: Postoperative nausea and vomiting (PONV) is reported to occur with a high incidence after strabismus surgery It has been suggested that this is related to an "oculo-emetic reflex", arising from extraocular muscle stimulation with a similar pathway to the oculocardiac reflex (1). Therefore, we studied whether the increase in muscle tone caused by a resection or combined recession-resection (RRP) procedure correlates with the incidence of postoperative vomiting (POV)

Materials and Methods: With approval of the local ethics committee 142 ASA 1 to 3 patients undergoing RRP were monitored for POV over 24 hours. Anaesthesia was induced with fentanyl 1.5 μg/kg or alfentanil 15 μg/kg and thiopentone 3–7 mg/kg and maintained with isoflurane or enflurane in O_2/N_2O 1 2 No antiemetics were used. Patients were assigned to one of seven groups according to the resulting shortening of extraocular muscles (in mm). Calculations of patients demographic and surgical data and the incidence of POV were performed with the Chi-square-test and logistic regression analysis $P < 0\,05$ was considered statistically significant

Results: There were no significant differences among the seven groups for sex and PONV in the patient's history, but for age. Therefore, additionally a logistic regression analysis was performed, revealing only age and sex as the main risk factors for POV as reported previously (2). There was no significant correlation between the shortening of muscles and the incidence of POV.



Conclusion: As no correlation between the incidence of POV and the shortening of muscles could be demonstated an increase in muscle tone is unlikely to cause an oculo-emetic reflex.

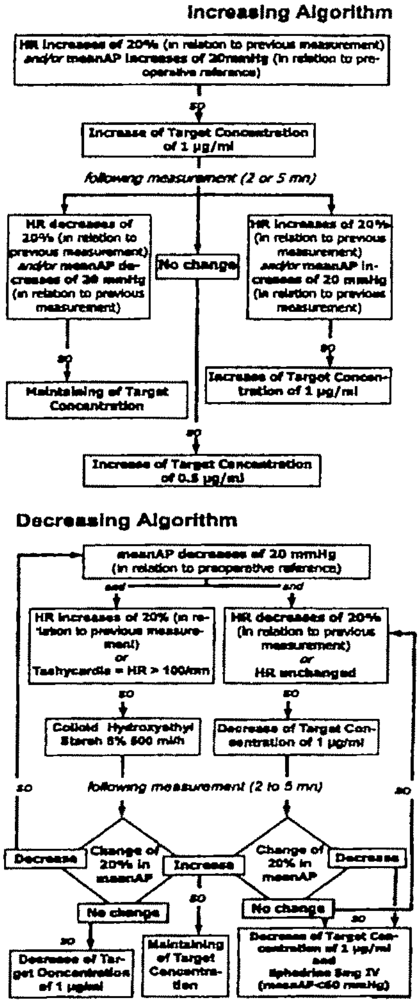
A.120 Decisional algorithms for target-controlled infusion of propofol in digestive endoscopy

P. Pandin[1], F. Degroote[1], P. Vanderlinden[1], A. Haché[1], F. Cantraine[2], L. Barvais[1], A. d'Hollander[1]. [1]*Department of Anaesthesiology, Erasmus Hospital, Brussels;* [2]*Department of Computer Science, Erasmus Campus, Brussels; Free University of Brussels, Belgium*

Goal of Study: The development of decisional algorithms for target concentration infusion (TCI) of anaesthetic drugs represents an attempt of adjustment more rational of anaesthesia to the differents levels of stimulation which occur during a surgical or an endoscopic procedure The aim of the study was to verify if it is possible to apply decisional algorithms elaborated to adapt the plasma target concentration (PTC) of propofol during gastrointestinal endoscopy.

Material and Methods: 22 ASA I, II patients, aged 18–65 years, undergoing interventional endoscopic retrograd cholangiography for biliary or pancreatic disease were studied (30 to 205 minutes) Patients were ventilated with an air/oxygen mixture General anaesthesia consisted in a TCI of propofol using the Marsh et al set (1). At the induction, PTC was 3 mcg/ml and every patient received an intravenous bolus of sufentanil (0 1 mcg/kg) and atracurium (0.5 mg/kg) to facilitate intubation After induction we recorded heart rate (HR), mean arterial pressure (MAP) every 2 minutes for 10 minutes and, after, every five minutes until the end of the endoscopy to adapt PTC (figure) We noted the reason of every adjustment of the PTC of propofol.



Increasing Algorithm
HR increases of 20% (in relation to previous measurement) and/or meanAP increases of 20mmHg (in relation to preoperative reference)

Decrease of Target Concentration of 1 µg/ml
Maintaining of Target Concentration
Decrease of Target Concentration of 1 µg/ml and Ephedrine 5mg IV (meanAP<60 mmHg)

The algorithms were based on our experience of the TCI of propofol during general surgery, on our knowledge of this kind of endoscopy and on recommendations of Everitt (2) Preoperatively, the reference MAP of each patient was determined, particularly in relation to previous hypertension (HT)

Results and Discussion: *First,* we can apply the decisional algorithms in all the patients without any problem for the investigators *Second,* the lenght of the anaesthesia does not interfere with the application of the algorithms, and there is not difference between short (<60 min) and long (>60 min) procedures. *Third,* the algorithms have generated propofol PTC of 3 to 8 mcg/ml and HR and MAP never change more of ± 20% The adjustments of the target concentration correspond with intubation, insertion of the endoscope and sphincterotomy in 77 2%, 31 8% and 22.7% of the patients, respectively Nevertheless, in 68.2%, PTC have been nsed without special event *Finally* the mean PTC required for the intubation (3 77 μg/ml), the endoscopy (4 09 μg/ml) and the sphincterotomy (4 27 μg/ml) do not differ significantly

Conclusion: Decision algorithms can be apply easily during TCI of propofol for digestive endoscopy and permit to rationalize the progress of the anaesthesiology, but it is necessary to know perfectly the endoscopic procedures.

A.121 Perioperative stress under different regimens of propofol and sufentanil for 'Fast-track'-anaesthesia in cardiac surgery

T. Uhlig, G Neumann, A. Pietsch, M Huppe[1], H. Kuppe, P Schmucker *Department of Anaesthesiology, Medical University of Lübeck,* [1]*Institute for Biological and Clinical Psychology, University of Würzburg, German Heart Center, Berlin, Germany*

Background: Propofol and sufentanil are commonly used for "fast-track"-anaesthesia in cardiac surgery. The prospective randomized study was designed to describe aspects of perioperative stress by using different regimes of total intravenous anaesthesia during surgery. By evaluating psychological and physiological aspects of stress simultaneously the study also asks for the most suitable doses of a propofol-sufentanil combination.

Methods: After approval of the local ethics commitee and written informed consent 72 patients awaiting elective coronary artery bypass grafting were studied. After induction of anaesthesia and endotracheal intubation the group was shifted by a 2 × 3-factorial design for maintenance of anaesthesia by using propofol (1.5 mg/kg/h vs. 2.0 mg/kg/h) and sufentanil (0.014 μg/kg/min vs. 0.021 μg/kg/min vs. 0.028 μg/kg/min). For describing perioperative stress either subjective (coping strategies, thinking about the surgery before and afterwards), either vegetative physiological (heart rate, blood pressure) and either neuroendocrinological (epinephrine, norepinephrine, renin, cortisol, ACTH) parameters were documented.

Results: No group differences were found in baseline-measures. During surgery patients under propfol 2.0 mg/kg/h showed lower expression of ACTH and cortisol after extracorporal circulation. These patients were extubated earlier than patients under 1.5 mg/kg/h propofol, who in tendency need more often rescue medication of propofol and/or sufentanil. There were significant interactions with sufentanil. Patients under sufentanil 0.014 μg/kg/min combined with propofol 2.0 mg/kg/h showed lowest expression of cortisol and ACTH after extracorporal circulation. There were corresponding results in vegetative physiological measurements. Alterations of heart rate and blood pressure were lower under propofol 2.0 mg/kg/h and in tendency lowest under propofol 2.0 mg/kg/h combined with sufentanil 0.014 μg/kg/min. Regarding psychological aspects, patients under propofol 2.0 mg/kg/h showed more positive coping strategies after surgery and in tendency thought more positive two days after surgery. Because of multiple comparisons, the results of the study are considered to be exploratory.

Conclusion: The results of the study indicate that a combination of propofol 2.0 mg/kg/h combined with sufentanil 0.014 μg/kg/min is a suitable regime for "fasttrack"-anaesthesia in cardiac surgery. The study also stresses the importance of a multi-dimensional psychophysiological approach for describing perioperative aspects of stress in cardiac surgery.

A.122 Balanced anaesthesia with remifentanil and propofol; a simplified administration protocol

F.E.A. Geisler, M.P. Boldin, J.F.A. Blommerde. *Dept. of Anesthesiology, Ignatius Ziekenhuis Breda, The Netherlands*

Introduction: Remi has a short onset time as well as a short offset of action which makes it a titratable opioid suitable to administer as a continuous infusion. The recommended maintenance dose has an 40-fold range which depends on the combined sedative component and individual patient reactions.[1] A simplified protocol based on the patients body weight and a "50%-rule" (1) was investigated during anesthesia for spondylosis-surgery.

Method: 40 patients were induced with propofol 1.5 mg/kg continued by 3 mg/kg/hr. A remi infusion (50 μg/ml) was started at an infusorspeed (ml/hr) corresponding to the patients' body weight. BP and HR were kept within 15 mm Hg and/or 15 bpm from baseline. Morphine, 0.2 mg/kg iv, was given 30 min before the end of surgery followed by PCA. 20 pat. were ventilated with N2O/O2 and 20 pat. with Air/O2. Maintenance dose, adjustments to the infusorspeed settings and the time to responding and extubation were recorded.

Results: Throughout the operation 1.6 resp. 1.5 adjustments/hr (2) were necessary to maintain an adequate level of anesthesia. With N2O the maintenance dose of remi was significantly lower than in the Air/O2 group. Following the end of surgery patients ventilated with N2O/O2, needed significantly more time to extubation compared to the TIVA group. In the recovery room painrelief proved to be satisfactory within 25 min. Postoperatively no differences between the groups could be registered.

Conclusion: Balanced anesthesia with remi in combination with a low dose of propofol can be administered according the patients weight and a simple 50%-rule. Only 1.5 adjustments/hr are necessary and patients ventilated with N2O/O2 need less remi for maintenance of anesthesia however, recovery is prolonged about 3-fold.

1. 50%-rule:	2. Results (mean/SD)	N2O/O2	O2/AIR

A.123 Remifentanil or fentanyl for carotid artery surgery

W. Wilhelm, J. Harrer, N. Schlaich, T. Ziegenfuß, M. Müller[1], R. Larsen
Klinik für Anaesthesiologie und Intensivmedizin; [1] Nervenklinik und Poliklinik, Universitätskliniken des Saarlandes, D-66421 Homburg/Saar, Germany

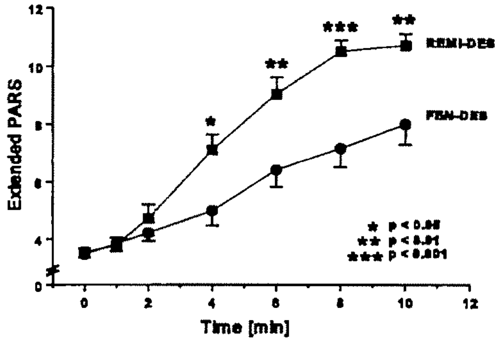
Introduction: Anaesthetic considerations for carotid endarterectomy (CEA) are conflicting regarding the use of opioids: a high-dose opioid technique is recommended because of coexisting coronary artery disease [1], but a low-dose regimen facilitates rapid postoperative awakening and early neurologic assessment [2]. The use of remifentanil may combine profound opioid analgesia intraoperatively with rapid recovery thereafter. Therefore, this study was designed to investigate the emergence profile after remifentanil-desflurane (REMI-DES) compared with fentanyl-desflurane (FEN-DES) anaesthesia.

Methods: With IRB approval and written informed consent patients (ASA II–III) scheduled for CEA were studied at random. Anaesthesia in the REMI-DES group consisted of REMI bolus (1 μg/kg), REMI infusion (0.1 μg/kg/min) and DES (2 Vol% endtidal). Patients in the FEN-DES group received FEN (2 μg/kg) before induction, FEN (2 μg/kg) at skin incision and DES as needed. With termination of surgery anaesthetic delivery was discontinued simultaneously and recovery times were recorded. The postanaesthetic recovery score (PARS) [3] was extended to 12 points including neurologic assessibility. Statistics: Mann-Whitney-U-test ($p < 0.05$); data as mean ± SEM.

Results: A total of 37 patients (REMI n = 18, FEN n = 19) was studied. Recovery times were significantly shorter for REMI-DES than for FEN-DES.

Recovery (min)	REMI + DES	FEN + DES	p-value
Extubation	3.9 ± 0.4	8.4 ± 1.1	0.001
Open eyes	3.7 ± 0.4	8.2 ± 1.2	0.002
State name	6.0 ± 0.7	14.2 ± 2.1	0.001

Furthermore, the patients ability to follow neurologic command testing was faster with REMI-DES than with FEN-DES.



Conclusions: Shorter recovery times and early neurologic assessibility recommend REMI-DES as a suitable alternative to fentanyl-based anaesthesia when used for patients undergoing CEA. These results are most probably explained by the unique pharmacokinetic properties of remifentanil. Additionally, the fentanyl-based anaesthesia regimen had to use higher endtidal concentrations of desflurane. Though desflurane is rapidly exhaled, this may have contributed to the time differences.

A.124 TIVA without narcotics for anaesthesia under field conditions: interest of ketamine

L. Bargues, Y. Auroy, F. Servin[1], B. Lenoir. *HIA PERCY, Clamart; [1] CHU BICHAT, Paris, France*

Background & Goal of the Study: Under field conditions, narcotics and anaesthesia machine can be difficult to obtain. The aim of this prospective randomised study was to compare a propofol-ketamine TIVA [2] with a inhalation technique or propofol-alfentanil TIVA.

Materials & Methods: After informed consent and institutional approval, 66 ASA I young males were randomly allocated in one of three groups. In group I, anaesthesia was induced with fentanyl 5 μg/kg, thiopental 5 mg/kg, vecuronium 0.1 mg/kg and maintained with isoflurane ≤1% end tidal. In group II, anaesthesia was induced with ketamine 1 mg/kg [1], propofol 2.5

mg/kg, vecuronium 0 1 mg/kg and maintained with propofol 10 mg/kg/h and ketamine 2 mg/kg/h In group III, anaesthesia was induced with alfentanil 30 μg/kg, propofol 2 5 mg/kg, vecuronium 0.1 mg/kg and maintained with propofol 10 mg/kg/h and alfentanil 20 μg/kg/h. All patients were intubated, had controlled ventilation with O_2-N_2O (33–66%) In group I and O_2-air (33–66%) in group II and III Fentanyl (1 μg/kg) or propofol (0.5 mg/kg) boluses were administered when anaesthesia was inadequate. The variation in systolic arterial pressure between preinduction and two minutes after intubation was calculated (ΔSAP) All drugs were discontinued simultaneously at the end of the procedure Statistical analysis included t-test and Anova.

Results: All groups were similar regarding to age, weight, kind of surgery (orthopaedic, general), duration of surgery.

	Group I	Group II	Group III
Duration anaesthesia (min)	69 ± 39	80 ± 30	74 ± 39
ΔPAS %	0 1 ± 1 3	11 6 ± 20*	−9 5 ± 13*
Number of boluses	0 3 ± 0 4*	2 1 ± 2 0	1 5 ± 2 1
Eyes opening (min)	15 ± 5	36 ± 16*	19 ± 7
Extubation (min)	16 ± 5	35 ± 17*	20 ± 7
PACU stay (min)	101 ± 29	131 ± 45*	98 ± 20

mean ± SD, *$p < 0$ 05 versus two others groups

In the PACU, EVA pain score at 30 min was higher in group II (3 3 ± 2 group I, 4.2 ± 2 group II, 3.4 ± 2 group III) whereas duration before first analgesic requirement (median 15, 37, 15 min) and % of patients requiring morphine (14, 27, 14%) were not statistically different.

Conclusions: Propofol-ketamine TIVA, although not better than the other general anaesthesias studied here, appears a suitable technique when the usual anaesthesic equipement or narcotics are not available. In clinical practice, titration of doses to effect may allow a more satisfying course of anaesthesia

A.125 Bispectral index: a decision or a problem of an estimation of anaesthesia depth?

V. Soubbotin, V. Vinogradov, O. Petrov, S. Juravel, V. Lickvantzev, V. Smirnova. *Department of Anaesthesiology, Surgery Institute n.a. Vishnevsky, Moscow, Russia*

An estimation of adequacy and depth of anaesthesia remains one of the basic problems in modern anaesthesiology. In last time a parameter, allowing to supervise intraoperational condition of patient's CNS, named bispectral index (BIS), has become applied. (1). But as this method is based on the spectral analysis EEG, it is quite possible, that it is not deprived of lacks, inherent in similar methods (2). The purpose of this research was to compare informativeness of bispectral index during different kinds of anaesthesia.

Materials & Methods: Three randomized groups of patients (10 in each group) undergoing abdominal surgery has been investigated. 1)-TVA (propofol/fentanil); 2)-general combined anaesthesia (isoflurane/fentanil); 3)-TVA (ketamine/fentanil). Bispectral index was recorded by the A-1000 (Aspect medical system ink., USA) Besides the control of hemodynamic parameters, for comparison of an estimation of anaesthesia depth SSEP's were monitored by the Nomad –3600 (Tracor Norther Ink, USA)

Results & Discussion: In 1) and 2) groups informativeness of bispectral index about anaesthesia depth and adequacy has appeared rather high and coincided with changes early SSEP's. Percent of concurrences was equal 80 in first and 70 the second groups In the third group bispectral index in most cases specified on patients awamess, while SSEP's and hemodynamic parameters informed on sufficient anaesthesia depth Percent of concurrences was equal 20.

Conclusion: Bispectral index is an effective parameter for an estimation of depth during propofol/fentanil and isoflurane/fentanil anaesthesia, but is not effective during ketamine/fentanil anaesthesia Thus at all advantages of this method it is impossible to recommend it as a universal method of an estimation of anaesthesia depth

A.126 Informational saturation of EEG *vs* bispectral index of EEG

V Lickvantzev, O Petrov, A Sitnikov, V. Soubbotin, L Kalinkin.
Department of Anaesthesiology, Surgery Institute n.a Vishnevsky, Moscow, Russia

The gold standard allowing to correspond EEG changes with anaesthesia depth is not yet found We attempt to decide this problem by monitoring of original informational EEG parameter named as an informational saturation of EEG (IN EEG)

Materials & Methods: Three randomized groups of patients (10 in each group) undergoing abdominal surgery were investigated 1)- TVA (propofol/fentanil); 2)- common combined anaesthesia (isoflurane/fentanil), 3)-TVA (ketamine/fentanil) Comparison of sensitivity of an offered method was carried out with bispectral index (A-1000 Aspect medical system ink , USA) and Auditory EP's (Nomad-3600, Tracor Norther ink., USA)

Results & Discussion: In the first and in the second groups investigated parameters correlated good with anaesthesia depth Factor of correlation was 0 87 for IN EEG and 0.81 for bispectral index Between two methods factor of correlation was 0 75 In the third group factor of correlation between anaesthesia depth and IN EEG was 0 71 v s 0 10 at bispectral index There was no correlation between investigated parameters

Conclusion: It is possible to assume, that both methods rather precisely reflect depth of anaesthesia during propofol/fentanil and isoflurane/fentanil anaesthetic technique, but during ketamine/fentanil anaesthesia bispectral index loses the informativeness, while the IN EEG allows to supervise anaesthesia depth However, the reason that influences on the informativeness of researched methods in one or another case was not revealed This is the main problem which constrains wide using of researched methods in automatic control of anaesthesia depth.

A.127 Bispectral EEG monitoring of deep breath inhalation induction of anaesthesia with sevoflurane

R Vermeulen, C De Deyne, M Struys[1], B. Claessens, G Vundelinckx, E. Vandermeersch[2], R Heylen *Depts of Anesthesia, ZOL Sint-Jan Genk; [1] University Hospital UZG, Gent; [2] University Hospital Gasthuisberg, Leuven, Belgium*

The introduction of sevoflurane has renewed the interest in the concept of mask induction in adult patients Because of its low blood-gas solubility and its nonpungent character, sevoflurane could be used both for induction and maintenance of anesthesia in adult patients. The objectives of this study were to observe the pharmacodynamic characteristics of sevoflurane inhalation induction. Bispectral analysis of the EEG is a signal processing technique that has been proposed as a pharmacodynamic measure of anesthetic effects on the central nervous system. It has been largely demonstrated that an empirically derived bispectral EEG measure, the bispectral index (BIS) is a significant predictor of depth of anesthesia

Methods: After approval of the local ethical committee, forty ASA I or II pts, scheduled for elective outpatient gynecologic surgery were included For induction, a deep breath inhalation induction (after maximal expiration) with sevoflurane 8% and a O2/N20 mixture (35/65%) was applied After loss of consciousness (LOC), sevoflurane was decreased to 4% and anesthesia was further maintained with sevoflurane in a O2/N20 mixture (35/65%) Further adjustment of sevoflurane administration was made according to clinical reactivity

Results: Anesthesia was succesfully induced in all pts. The time to LOC was m45 sec (SD 18 sec) at an ET Sevo of 4 8% (SD 1 7%). BIS started to decrease at the time of LOC reaching a minimal value at a mean of 40 sec later Mean BIS reached after induction was 24 (SD 13). At surgical stimulation (mean BIS of 39, SD 10 and mean ET sevo of 2 9% SD 0 8%) 8 pts had clinical signs of inadequate anesthesia. In all 8 pts, BIS was above 45 and showed a significant increase (+20%) in response to surgical stimulation

Conclusion: Loss of consciousness after sevoflurane deep breath inhalation induction occurred at a mean of 45 sec for an ET sevo around 4 MAC, which is higher than previously reported for quiet breath sevoflurane inhalation induction. The BIS value was an excellent predictor of reaction to surgical stimulation, as all pts with a BIS above 45 reacted to surgical stimulation in a sevoflurane/O2/N2O anesthesia.

A.128 Patient-tailored sevoflurane anaesthesia guided by bispectral EEG

H. Keyer, C De Deyne, M Struys[1], K. Vissers, R De Jongh, L Merckx, E. Vandermeersch[2], R. Heylen *Depts of Anesthesia, ZOL Sint-Jan, Genk, [1] University Hospital UZG, Gent, [2] University Hospital Gasthuisberg, Leuven, Belgium*

The Bispectral Index (BIS) has been shown to be a quantifiable measure of the effects of anesthetics on the central nervous system. Previously, titration of anesthetics was guided by knowledge on dose-response curves for anesthetics and by clinical reactivity to noxious stimulation. In the present study, we tried to assess the anesthetic requirements when using a BIS-guided sevoflurane anesthesia

Methods: Twenty unpremedicated ASA I or II pts scheduled for laparoscopic abdominal surgery were studied Anesthesia was induced with 8% sevoflurane deep breath inhalation and N2O/O2 (65/35%) After induction of anesthesia, sevoflurane (in a N2O/O2 mixture: 65/35%) was adjusted in order to maintain BIS between 45 and 55. No intravenous opioids were administered (local infiltration of surgical wounds was performed by surgeon). From 10 min after induction (achieving a stable level of anesthesia) until 10 min before skin closure (when BIS was allowed to return to 60–75) all end-tidal (ET) sevoflurane concentrations were recorded per minute and a mean value/minute was calculated.

Results: Using a BIS-guided sevoflurane mono-anesthesia, mean anesthetic requirement was 1.76% ET sevo (SD 0.78) or a mean of 1.5 MAC. We observed a wide inter-individual range in required anesthetics between a mean of 0 98% and a mean of 4.4% ET sevoflurane required to maintain a peroperative BIS between 45 and 55.

Conclusion: Using a BIS-guided sevoflurane mono-anesthesia in unpremeditated pts we found a large inter-individual variability (fourfold difference) in anesthetic needs, demonstrating that EEG-BIS monitoring might be useful in improving the titration of volatile anesthetics

---

A.129 Clonidine pretreatment does not reduce anaesthetic requirements in bispectral EEG-guided sevoflurane anaesthesia

M. Vanderlaenen, C. De Deyne, M. Struys[1], H Keyer, P. Van Leuven, J Van Canneyt, L Buyse, R. De Jongh, E Vandermeersch[2], R. Heylen
Depts of Anesthesia, ZOL Sint-Jan, Genk, [1] University Hospital UZG, Gent; [2] University Hospital Gasthuisberg, Leuven, Belgium

Clonidine is an alpha2-adrenergic agonist with sedative-hypnotic and analgesic properties. When used as adjuvants in general anesthesia, alpha2-adrenergic agonists are reported to reduce anesthetic requirements. Previous studies have demonstrated that an emperically derived EEG measure, the bispectral index (BIS), is a significant predictor of depth of anesthesia. We conducted a placebo controlled trial to assess the anesthetic effects of clonidine. Therefore, the anesthetic requirements in a BIS-guided sevoflurane anesthesia in pts pretreated with clonidine were analysed.

Methods: Twenty ASA I or II patients scheduled for laparoscopic abdominal surgery were investigated. Pts were unpremedicated and were randomly allocated to receive either intravenous saline solution or clonidine 3 μg/kg in a saline infusion over a 10 min period, 15 min prior to anesthesia. Anesthesia was induced by 8% sevoflurane deep breath inhalation and was maintained by sevoflurane in a mixture of N20/02 (65/35%) in order to maintain a BIS between 45 and 55. All surgical incision wounds were locally infiltrated (with bupivacaine) by the surgeon. From 10 min after induction (achieving a stable level of anesthesia) until 10 min before skin closure (when BIS was allowed to return to 60–75) all end-tidal (ET) sevoflurane concentrations were recorded per minute and a mean value/minute was calculated. Differences in anesthetic requirements (ET sevo) were analysed with a Wilcoxon signed rank test.

Results: Both groups were demographically similar with no significant differences between them in terms of age, weight or height, or in operative time (mean of 51 min). Mean anesthetic requirements in placebo pretreated pts were not statistically different from clonidine pretreated pts (1.79 ET sevo (SD 0.76) for placebo group vs 2 05 ET sevo (SD 0.94) for clonidine pretreated group).

Conclusions: Using a BIS-guided sevoflurane anesthesia, we were not able to conclude to a reduction in anesthetic requirements after clonidine pretreatment

---

A.130 Bispectral index and calculated plasma concentrations of propofol and sufentanil during emergence from target-controlled anaesthesia

P. Hans, B. Hubert, J.F. Brichant, P.Y. Dewandre, W. Dewé, A. Albert, V. Bonhomme, M. Lamy *University Dpt of Anesthesia & Intensive Care Medicine, Dpt of Biostatistics, CHR de la Citadelle, CHU Liege, Belgium; Dpt of Anesthesia, Mc Gill University, Montreal, Canada*

Background and Goal of the Study: The Bispectral index (BIS) is a new processed EEG variable correlated with the hypnotic effect of anesthetic agents. The present study was designed to analyse BIS and calculated plasma concentrations of propofol (PPF) and sufentanil (SUF) during emergence from target-controlled anesthesia.

Materials and Methods: After approval by the Ethics committee, we studied 28 ASA I or II consenting patients, scheduled for elective surgery under general anesthesia. Premedication consisted in 1 mg alprazolam given orally 1 h before surgery. Anesthesia was induced and maintained with PPF and SUF using a computer-controlled infusion device. Tracheal intubation was facilitated with atracurium and ventilation was controlled with air/oxygen. The end-tidal CO_2 was maintained close to 30 mmHg and rectal temperature remained above 35.5°C throughout the study. After completion of surgery, BIS values and calculated plasma concentrations of PPF and SUF were recorded at the following patient's recovery steps: recovery of spontaneous breathing (SB: respiratory rate $>8\ \text{min}^{-1}$ and end-tidal $CO_2 <$ 45 mm Hg), eye opening (EO) to command, and recall of birthday (BD). BIS values and calculated plasma concentrations of PPF and SUF at the different steps of recovery were analysed using repeated measures ANOVA. The calculated plasma concentrations of PPF and SUF were fitted by regression analysis at each end point. The prediction probabilities of the degree of recovery were also determined for BIS and the calculated concentrations of PPF and SUF (1). $P < 0\ 05$ was considered statistically significant

Results: Results were expressed as means (SD). Calculated plasma concentrations of PPF and SUF decreased significantly and BIS increased significantly from SB to EO and from EO to BD (table). A significant correlation was observed between PPF and SUF concentrations at SB, EO and BD (r = 0 55, 0.65, 0 62), respectively. The prediction probability was 0.94 (0.13) for PPF, 0.92 (0.15) for SUF and 0 89 (0 16) for BIS

	SB	EO	BD
Calc PPF conc (μg/ml)	1 78 (0 35)	1 62 (0 28)*	1 46 (0 21)#
Calc SUF conc (ng/ml)	0 080 (0 007)	0 079 (0 007)*	0 076 (0 007)#
BIS	72 5 (12 8)	77 9 (12 0)*	92.4 (6 6)#

*significantly ≠ from SB, #significantly ≠ from EO and SB

Discussion: BIS values and calculated plasma concentrations of PPF and SUF changed significantly during the different steps of recovery. The high correlation observed between PPF and SUF at each end point might be ascribed to individual variability in drug response and could reflect the absence of drug interaction in their range of concentrations. When considered alone, the calculated concentration of PPF provided a better prediction of recovery than the calculated concentration of SUF and BIS

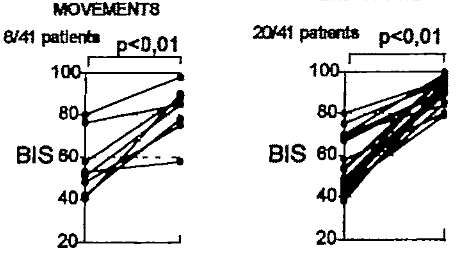
A.131 Variations of bispectral index during peroperative movements and recovery from isoflurane anaesthesia

B. Guignard, C Menigaux, C Coste, M. Chauvin. *Département d'anesthésie, Hôp A Paré, 92104 Boulogne, France*

Background: Previous studies demonstrated that bispectral index (BIS) monitoring can be used to assess the hypnotic effects of anesthetics[1]. Values superior to 90 assess awaking. The time of calculation of BIS – 40 seconds – don't make it a real instant EEG parameter. The present study evaluated BIS variations during peroperative movement and during end of isoflurane anaesthesia.

Material & Methods: After institutional approval, we studied 41 ASA 1 or 2 patients scheduled for general surgery. All patients received induction using propofol (2–3 mg/kg) and sufentanil (0.2 mcg/kg). Vecuronium (0.1 mg/kg) was used to facilitate intubation. Patients breathed N_2O/O_2 (FIO_2 = 0.5). BIS (Aspect Medical System A-1000 EEG monitor) was recorded every 5 seconds and was blinded to the anaesthesia provider. When a patient present an intraoperative movement, time was noted at the second BIS values at the movement (mvt) and one minute after (mvt + 1 min) were analysed. The pulse rate, MAP were also monitored. Data were analyzed using Student's t-test or Chi square test. $P < 0.01$ was considered significant

Results: 8/41 patients presented peroperative movement, BIS at this time was 56 ± 16, compare to 82 ± 11 one minute after (mean ± sd, Figure 1 A). At the end of anaesthesia, half of the patients present rapid variation of BIS: 55 ± 12 to 87 ± 11 in one minute (Figure 1 B). In the other patients BIS values progressively reach 90.



Conclusion: Peroperative variations of BIS under isoflurane and low dose sufentanil could be rapid, with an increase of surgical stimulation, or with a constant stimulation: orotracheal tube at the end of anaesthesia. These data suggest that interpretation of BIS is time dependant, and clinical situation has to be taken into account.

A.132 Dose-response relationship between target-controlled concentration of propofol and bispectral index

M Malinge, F. Petitfaux, J Y Lepage, J.M. Malinovsky, A Cozian, M. Pinaud. *Service d'Anesthésie-Réanimation Chirurgicale, Hotel-Dieu 44035 Nantes Cedex, France*

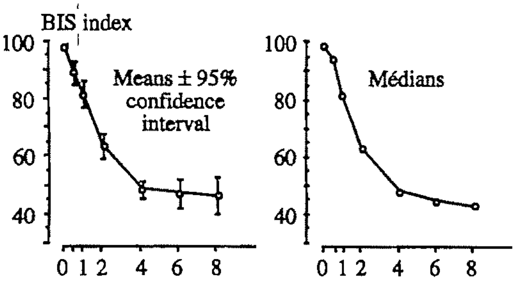
Background and Goal of Study: Bispectral index (BIS) allows a quantitative EEG measure of anesthetic effect Recently, Leslie et al (1) showed that BIS linearly relates to propofol blood concentration in volunteers. This study was designed to characterize the relationship between propofol target-controlled concentration and BIS in surgical patients

Material and Methods: 30 consenting males (ASA I–II, 18–50 yr, 50–80 kg) having elective urogenital surgery were studied before surgery, after institutional committee approval. After oral diazepam (0 2 $mg.kg^{-1}$), each patient was administered a dose-ranging sequence of propofol using a computer-controlled infusion device (STELPUMP) Assigned target site effect concentrations of 0, 0.5, 1, 2, 4, 6 and 8 $\mu g\ ml^{-1}$ were maintained for 3 min. EEG was acquired from a bifrontal montage using the Aspect A-1000 monitor™ (Spacelab). Electrode impedances were maintained below 5000 ohms. BIS was recorded on a 15 s basis during the 3rd minute of steady state, using the 4D software (Macintosh). Each BIS score was the average of 4 recorded values Statistical analysis was made using linear regression analysis Data are presented as means ± 95% CI and medians

Results and Discussion:

(1) BIS was linearly related to propofol target site effect concentration in the concentration-ranging 0–4 $\mu g.ml^{-1}$ (BIS = −12 5 * [target] + 99.8, r = 0 87; n = 150).

(2) The target concentration of 4 $\mu g\ ml^{-1}$ produced a mean BIS score of 47 (CI 44–50), indicative of hypnosis Further increases in target concentration did not affect BIS significantly, due to the anesthetic interventions required for maintaining adequate airway. Manual ventilation was needed in the range of 4.8–7 6 $\mu g\ ml^{-1}$



Target effect site concentration ($\mu g.mL^{-1}$)

The estimated value of BIS_{95} for loss of consciousness with propofol is 51 (95% CI 48–55) (2) Based on the relation of BIS to target concentration, our data suggest that a target site effect concentration in the range of 3.6–4.1 $\mu g.ml^{-1}$ correlates with BIS_{95}.

Conclusion: The target-controlled site effect concentration of propofol required to induce anesthesia arounds 4 $\mu g\ ml^{-1}$ in healthy male patients premedicated with diazepam

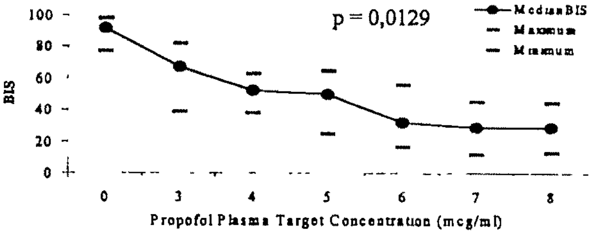
A.133 Matching sympathetic response of visceral pain with propofol target-controlled infusion: a blinded bispectral study

P. Pandin[1], F. Degroote[1], P. Vanderlinden[1], F. Cantraine[2], L. Barvais[1], A. d'Hollander[1]. [1] *Department of Anaesthesiology, Erasmus Hospital, Brussels;* [2] *Department of Computer Science, Erasmus Campus, Brussels; Free University of Brussels, Belgium*

Goal of Study: The digestive endoscopy corresponds to a pure visceral pain with sympathetic stimulation and excludes the other afferences (skin, wound and articulations). In a recent multicenter study, Sebel et al (1) have proven that the Bispectral encephalogram analysis (BIS) correlates best with the effects of primary hypnotic-based anaesthetic techniques. The aim of the study was to verify, in case of a pure visceral pain, the correlation between the plasma target concentration (PTC) of propofol and the BIS.

Material and Methods: 22 ASA I, II patients, aged 18–65 years, undergoing interventional endoscopic retrograd cholangiography for biliary or pancreatic disease were studied (30 to 205 minutes). Premedication consisted in intramuscular 0.1 mg/kg of midazolam 30 minutes before endoscopy. Patients were ventilated with an air/oxygen mixture. We used a TCI of propofol with the Marsh et al set (2), and the initial PTC was 3 mcg/ml. Every patient received at induction intravenous sufentanil (0.1 mcg/kg) and atracurium (0.5 mg/kg) to facilitate intubation. We used decisional algorithms to modify the PTC of propofol based on the heart rate (HR) and the mean arterial pressure (MAP) trends BIS was recorded every 2 minutes for 10 minutes, and after every 5 minutes until the end of the endoscopy, but it was hidden from view of the investigators, and so, could not interfere with the anaesthesia progress. First, we determined the median of the recorded BIS for the different observed propofol PTC in every patient. Second, the median of these 22 median BIS was calculated for every PTC (figure). The minimal and the maximal calculated values of the median BIS for each PTC represent the dispersion of the measures (figure)

Results and Discussion: Decisional algorithms have generated propofol PTC of 3 to 8 mcg/ml.



Using the Friedman test, the different levels of BIS are statistically differents for the observed PTC of propofol, and even in case of a pure visceral pain, the results are comparable to these ones of Sebel et al (1) published for skin and wound incision The median BIS at the induction (92) probably reflects the effect of premedication. Moreover, data analysis permits to calculate the median BIS for the intubation, the insertion of endoscope and the sphincterotomy (62, 58.25 and 52 5 respectively)

Conclusion: Our results show a correlation between the BIS and the PTC of propofol even in case of pure visceral stimulations and the BIS can be considered as an acceptable index of the cortical effect of the anaesthesia.

A.134 Improved anaesthetic titration using the bispectral index of the EEG in malignant obese patients

M. Verlaeckt, C De Deyne, M. Struys[1], K Vissers, R. De Jongh, L Buyse, E. Vandermeersch[2], R Heylen *Depts of Anesthesia, ZOL Sint-Jan, Genk,* [1] *University Hospital UZG, Gent;* [2] *University Hospital Gasthuisberg, Leuven, Belgium*

Dose-response relationships for anesthetic drugs and clinical reactivity (changes in autonomic and somatic responses) to noxious stimulation are todays clinical guide to titrate anesthetic drugs Bispectral analysis of the EEG is a signal processing technique that has been proposed as a pharmacodynamic measure of anesthetic effects on the central nervous system The Bispectral Index (BIS), an empirically derived bispectral EEG measure, was reported as a significant predictor of depth of anesthesia. This prospective, randomized study assessed the effects of a BIS-guided anesthesia on anesthetic requirements in malignant obese patients

Methods: Thirty female ASA I or II pts with a BMI greater than 40 and scheduled for laparoscopic gastric banding were included Pts were randomly allocated to receive standard clinical practice (SP) or BIS-guided anesthesia. In both groups anesthesia was induced with propofol (1 mg/kg), alfentanil (50 $\mu g/kg$) and cisatracurium (0 15 mg/kg), to facilitate endotracheal intubation. Anesthesia was maintained with propofol (6 mg/kg/hr), alfentanil (40 $\mu g/kg/hr$) and N2O/O2 (65/35%) In the SP group, anesthesia was titrated by clinical reactivity to noxious stimuli (increase or decrease of propofol and alfentanil with 10%), while in the BIS-group anesthesia was guided to maintain a BIS between 45 and 55. Out of these borders, propofol and alfentanil were increased or decreased with 10%. Statistical analysis was performed using a Wilcoxon ranked test.

Results: Both groups were demographically similar with no significant differences between them in terms of age, weight or height, or in operative time. Total anesthetic administration was significantly lower in the BIS-group compared to the SP group. Mean need of propofol and alfentanil was, respectively 6.3 mg/kg/hr and 41.5 $\mu g/kg/hr$, in the SP-group, while in the BIS-group mean need of propofol was 4.8 mg/kg/hr and 32.5 $\mu g/kg/hr$ of alfentanil. A large variation in anesthetic requirements was observed in the BIS-group with a range between 3 2 to 7.8 mg/kg/hr for propofol and 24 to 52 $\mu g/kg/hr$ for alfentanil.

Conclusion: Anesthesia guided by BIS resulted in the administration of less anesthetics. Especially in patients with an increased body weight, titration of anesthetics to pharmacodynamic effects might result in a superior anesthetic management.

A.135 Bispectral index of EEG does not predict haemodynamic responses to laryngoscopy and intubation under sevoflurane anaesthesia

P Van Leuven, C. De Deyne, M. Struys[1], R De Jongh, M. Cauberghs, G Goossens, H. Adriaensen[2], R. Heylen. *Dept of Anesthesia, ZOL Sint-Jan, Genk, [1]University Hospital UZG, Gent; [2]University Hospital UZA, Antwerpen, Belgium*

The Bispectral index (BIS) has been reported as a significant predictor of depth of anesthesia. Earlier reports have indicated that a BIS below 50, after induction of anesthesia, is consistent with an adequate level of anesthesia. The aim of this report was to observe the cardiovascular responses on intubation after sevoflurane inhalation induction in pts revealing an adequate depth of anesthesia (BIS below 50).

Methods: Thirty pts scheduled for out-patient surgery were included. For induction, a deep breath inhalation induction with sevoflurane 8% in a O2/N2O mixture (35/65%) was applied. After loss of consciousness, sevoflurane was decreased to 4%, ventilation was assisted and cisatracurium (0.15 mg/kg) was given to facilitate orotracheal intubation Bispectral EEG monitoring was performed in a bifrontal referential montage using an Aspect-1000 EEG monitor. BIS, heart rate (HR), systolic and diastolic blood pressure (SBP, DBP) were recorded before induction (base), just before intubation, and at their heighest value within 2 min after intubation. Intubation was not attempted until BIS was lower than 50

Results: Anova was used for statistical analysis and values are shown as mean and standard deviation (SD).

	Base	Pre-intub	Post-intub
BIS	96 1 (2 0)	30 (8.5)	44 5 (9 7)
SBP	128 (13 5)	104 (10 2)	50 2 (18 8)
DBP	79 (16 5)	64 (12.7)	103 (18 6)
HR	79 1 (13 8)	76.4 (10 8)	93 (12 7)

Although BIS was below 50 in all pts before attempting intubation, SBP, DBP and HR increased significantly after intubation compared with the baseline values There was a good correlation between increases in hemodynamic parameters and increase in BIS, reflecting the cerebral cortex activity on intubation

Conclusions: These results indicate that sevoflurane inhalation anesthesia is not effective to prevent hemodynamic responses on intubation at anesthetic depth of BIS within 30 (SD 8.5). Therefore, BIS can not predict the hemodynamic responses to intubation under sevoflurane anesthesia.

A.136 Comparison of SEF and BIS by using two devices for electroencephalography under different regimens of induction of anaesthesia in cardiac surgery

T Uhlig, A. Schöffel, H. Adams, M. Huppe[1], H. Kuppe[2], P. Schmucker. *Department of Anaesthesiology, Medical University of Lübeck; [1]Institute for Biological and Clinical Psychology, University of Wurzburg; [2]German Heart Center, Berlin, Germany*

Background: The EEG bispectral index (BIS) is considered to be a sensitive parameter for describing as well depth of anaesthesia as well lost of consciousness. So the BIS might be also suitable for monitoring induction of anaesthesia in high-risk-patients, where titration of the drugs used is very important to avoid complications. It has to be asked, whether the BIS is comparable or probably more suitable than other EEG-markers, such as the spectral edge frequency (SEF) Thereby a bias of two different devices for calculating the SEF has probably to be taken into account. The prospective single-blinded randomized study was designed to evaluate different regimes of induction of anaesthesia in cardiac surgery by using the BIS and SEF of two different devices.

Methods: After approval of the local ethics commitee and written informed consent 48 patients awaiting elective coronary artery bypass grafting were studied. Four different regimes for induction of anaesthesia were used:

Regime 1: Continuous application of Midazolam (4 Minutes) up to 0.07 mg/kg, followed by continuous application of Sufentanil (4 Minutes) up to 0 7 μg/kg, followed by a bolus of 20 ml of sodium chloride, followed by a bolus of 0 2 mg/kg Ethomidate.

Regime 2: Continuous application of Sufentanil (4 Minutes) up to 0.7 μg/kg, followed by continuous application of Midazolam (4 Minutes) up to 0 07 mg/kg, followed by a bolus of 20 ml of sodium chloride, followed by a bolus of 0.2 mg/kg Ethomidate.

Regime 3: Continuous application sodium chloride (8 Minutes) followed by a bolus of Midazolam 0.07 mg/kg and Sufentanil 0.7 μg/kg in a total amount of 20 ml, followed by a bolus of 0.2 mg/kg Ethomidate.

Regime 4: Continuous application of Propofol up to 2 mg/kg followed by a bolus of 20 ml of sodium chloride, followed by a bolus of Midazolam 0.07 mg/kg and Sufentanil 0.7 μg/kg in a total amount of 20 ml.

By using the Aspect B500 monitor the BIS and SEF was monitored. By using the Dräger pEEG monitor the SEF was monitored simultaneously The EEG was documented from the beginning of induction of anaesthesia up to the beginning of surgery Heart rate, blood pressure and oxygen saturation were documented.

Results: As well the BIS as the SEF changed as expected during the period of induction of anaesthesia. Before endotracheal intubation values were lower than at the beginning of induction There were high correlations between the two devices used in the study Both devices and parameters show differences between the regimes of induction of anaesthesia, showing smooth and moderate changes of EEG under regime 1, 2 and 4 Under regime 2 patients showed more often signs of thoracic rigidity, which were correlated with significant changes of the BIS but not the SEF and were followed by a temorary decrease of oxygen saturation and increase of heart rate.

Conclusions: The BIS is a very sensitive parameter for monitoring the loss of consciousness during induction of anaesthesia. There are also different changes under different regimes of induction More data are neccessary to clear the importance of the BIS in detection of complications during anaesthesia

A.137 Who or which predicts anaesthetic depth better – the bispectral index of the EEG, pupillary responses to light or anaesthesiology residents?

C. Sitzwohl[1], M. Winkler[1], P. Nagele[1], A. Bacher[1], A. Blaicher[1], T. Weber[1], D.I. Sessler[2 1]. *[1]Departments of Anesthesia, University of Vienna A-1090 Vienna, Austria; [2]University of California, San Francisco, USA*

Background: Estimating anesthetic depth is a daily challenge for anesthesiologists Several methods of monitoring depth have been proposed, including hemodynamic responses, esophageal contractility, and electroencephalography However, none has proved sufficiently easy and reliable for routine use. Two recently introduced anesthetic depth monitors appear to have considerable potential: the bispectral index of the electroencephalogram and the amplitude of the pupillary light reflex.[1–3] However, it is not known whether either predicts anesthetic depth better than anesthesiologists. We therefore asked whether the bispectral index or pupillary light reflex predicts movement during routine surgery better than anesthesiology residents. We further tested the hypothesis that anesthesiologists would predict movement better during isoflurane/fentanyl anesthesia than during propofol/fentanyl anesthesia.

Methods: With IRB approval, 71 patients undergoing routine urology and obstetrical surgery were anesthetized by 9 anesthesia residents in their 1st, 2nd or 3rd years of training After induction of anesthesia, (propofol, fentanyl, succinylcholine) patients were randomly assigned to propofol or isoflurane maintenance anesthesia Patients assigned to volatile anesthesia were maintained with isoflurane in 70% N_2O; additional bolus doses of fentanyl were administered as deemed necessary The others were maintained by a continuous infusion of propofol in 70% N_2O; again, additional bolus doses of fentanyl were administered as deemed necessary by the anesthesiologists based on traditional signs and clinical judgment. (The anesthesiologists were not given access to electroencephalographic or pupillary data during the study) No additional muscle relaxants were administered The anesthesiologists estimated anesthetic depth on a subjective scale from 1 to 4, where 1 = ready for extubation, 2 = shallow anesthesia, 3 = adequate anesthesia, and 4 = very deep anesthesia. The bispectral index (Aspect A-1000, Aspect medical Systems, Natick, MA), pupillary light reflex (Fairville Medical Optics, Inc , Amersham, England), heart rate, systolic blood pressure, and anesthesiologists rating were recorded every third minute by an independent observer throughout anesthesia. Patient movement was also registered by the independent observer. Statistics were computed using t-test for independent samples. Data presented as means ± SDs.

Results: Duration of surgery was 142 ± 36 minutes, time from the end of operation until extubation was 5 ± 7 minutes During the 37 isoflurane anesthetics (969, 3-minute epochs), there were 25 movement episodes, during 34 propofol anesthetics (744, 3-minute epochs), there were 15 movement episodes.

Table Mean ± SD of different indicators of anesthetic depth before movement and no-movement epochs.

	Bispectral Index	Light Reflex (mm)	Clinical Score	Systolic BP (mmHg)	Heart rate (bpm)
Isoflurane no move	45 ± 19	0 09 ± 0 06	3 2 ± 0 6	103 ± 17	64 ± 12
Isoflorane move	53 ± 17	0 11 ± 0 03	3 0 ± 0 5	104 ± 10	66 ± 11
Propofol no move	45 ± 16	0 11 ± 0 02	3 2 ± 0 6	106 ± 18	64 ± 10
Propofol move	53 ± 16*	0 11 ± 0 02	3 ± 0 7	100 ± 16	62 ± 11

*$P < 0\ 05$

Conclusion: The incidence of movement was comparable during each type of anesthesia The Bispectral Index of EEG proved the only effective predictor of movement during routine surgery and propofol anesthesia.

A.138 Transcranial near infrared spectroscopy and EEG during cardiopulmonary bypass

P Durak, J Şenyurt, O Erdemlı, S. Ebıl. *Turkiye Yuksek Ihtısas Hospıtal, Sıhhıye, Ankara/06100, Turkey*

Background and Goal of the Study: Transcranial near infrared spectroscopy (NIRS) provides regional on line measurement of saturation of hemoglobin in a specific sampling of brain tissue (1). It allows therefore the non invasive evaluation of oxygen extraction of the brain parenchyma This method helps to monitor the continuous regional cerebral oxygen saturation (rSO2) (2) The EEG represents the summation of spontaneous electrical activity arising from postsnaptic potentials primarily from the superficial layers of the cerebral cortex. The rational for using an EEG is to see the changes of frequency activity and amplitude of the waves with respect to cerebral perfusion (3)

The aim of this study was to assess the changes in rS02 using NIRS and SEF using EEG together, during different stages of cardiac surgery.

Materials and Methods: The probe of the NIRS (Somanetic Corporation Troy, MI, USA) was positioned on the right side of the forehead Two channel EEG (fronto-mastoid) was recorded using Neurometrics Life Scan EEG machine The SEF was set at 95% level and EEG was continously recorded during the study. The measurements were recorded at seven times: T1· Before induction, T2: Immediately after the induction, T3. Immediately after CPB, T4: Hypothermia, T5. Rewarming, T6· Post CPB Statistical. analysis was performed by ANOVA and multiple linear regression analysis, ($p <$ 0.05) was considered as significant.

Results and Discussion: Values of rSO2 recorded were T1· 68.40 ± 7.43, T2· 72 93 ± 9 1, T3 57.86 ± 9.1 T4 57 93 ± 10 39, T5. 60 93 ± 6.29, T6: 64.93 ± 8.50. Values of SEF recorded were T1: 14 26 ± 2.5, T2· 9 6 ± 3.6, T3: 4.8 ± 3 3, T4. 3.56 ± 2.92, T5· 6 04 ± 4.35, T6 7 1 ± 3.8 There was a significant increase in rSO2 and decrease in SEF values after high dose fentanyl induction ($p < 0.05$) As soon as CPB was started there was a significant decrease in both rSO2 and SEF values caused by hemodilution ($p <$ 0 05). The first rSo2 value immediately after CPB was considered as the baseline value for the CPB period The lowest rSo2 and SEF value of the CPB was measured during deepest hypothermia which was 29°C ($p <$ 0.05) There was a positive correlation between the rSO2 and temperature when Hb and Htc values of CPB were constant ($r =$ 0 73).

Conclusion: In this clinical study noninvasive cerebral oxygen saturation recording (NIRS) indicated that high dose fentanyl induction resulted with the greatest increase in rSO2 and decrease in SEF values which may be contributed to the decrease in cerebral metabolic rate. With the Initation of the bypass and hemodilution effect the EEG and SEF value was lowered but rSo2 changed with a positively correlated way with the temperature when Hb and Htc is constant

As a result we concluded that rSO2 values of cerebral oxymeter and SEF values of EEG changed in a pozitively correlated way but rSO2 always changed earlier than the SEF in all stages of CPB and returned to the preinduction levels later than the rSO2

A.139 Comparative study of the TOF ratio measured by the TOF guard with and without thumb repositioning

K. Pelgrims, B F. Vanacker, E. Vandermeersch *Department of Anaesthesiology, U.Z. Gasthuisberg, Leuven, Belgium*

Background and Goal of Study: In clinical anaesthesia, tactile evaluation of the muscle response evoked by a nerve stimulator is the usual method employed to assess muscular block A more sensitive method should be used to evaluate decuransation[1]. The aim of this study was to evaluate whether by applying a load of 0 5 Newton (N) to the thumb, and thereby repositioning the thumb to its starting position, altered TOF-count or TOF-ratio during a TOF-stimulation with the TOF-Guard.

Materials and Methods: With Ethic committee approval and informed consent thirteen male patients (age 18–65, ASA I&II) were included in the study A piezoelectric accelerometer on the thumb was used by the TOF-Guard (ORGANON TEKNICA NV), one thumb with and the other thumb without a load of 0.5 N Anaesthesia was induced with sufentanil (0.3 μg kg^{-1}) and propofol (2 mg.kg^{-1}) and maintained with a propofol infusion (8 mg.kg^{-1}.h^{-1}). Four and a half minutes after induction of anaesthesia both TOF-Guards were autocalibrated. Five minutes after induction of anaesthesia rocuronium (0 6 mg.kg^{-1}) was administered Patients were allowed to decuranse spontaneously and TOF-ratio was measured up to 0 9 on both TOF-Guards [2]. Comparisons within patients were done using the paired t-test (1° line) and the Wilcoxon signed-rank test (2° line) $P \leq$ 0 05 was considered statistically significant

Results: Neuromuscular data ($n = 13$) in Table 1.

Parameter	With preload minus without preload	p-value
TOF 25% mean (SD)	−2 0 (4 9)	0 17
(min) median	−1 3	0 17
TOF 50% mean (SD)	−1 5 (3 4)	0 13
(min) median	−1 0	0 18
TOF 75% mean (SD)	−0 8 (4 9)	0 55
(min) median	−0 3	0 51
TOF 90% mean (SD)	0 0 (5 3)	0 99
(min) median	0 8	0 92

Conclusion: Applying a load of 0 5 N made no difference to the TOF-ratio when measured by the TOF-Guard. Therefore it can be concluded that as long as the thumb has a free area of movement a pre-load is not necessary

A.140 Comparative study of the TOF ratio measured by the ParaGraph *vs* the TOF guard

K. Pelgrims, B.F. Vanacker, E. Vandermeersch. *Department of Anaesthesiology, U Z. Gasthuisberg, Leuven, Belgium*

Background and Goal of Study: Mechanomyography with a force transducer is used as the reference standard This method, as well as the measurement of acceleration can be used for monitoring neuromuscular blockade [1]. This study was designed to compare the TOF-count and TOF-ratio measured by the ParaGraph versus the TOF-Guard with a load of 0 5 Newton.

Materials and Methods: With Ethic committee approval and informed consent twelve male patients (age 18–65, ASA I&II) were included into the study. The ParaGraph (UTAH MEDICAL PRODUCTS INC) uses a piezoelectric sensor on the palm of the hand to measure the evoked acceleration of the thumb [2] Anaesthesia was induced with sufentanil (0 3 μg kg^{-1}) and propofol (2 mg kg^{-1}) and maintained with a propofol infusion (8 mg kg^{-1}.h^{-1}) Four and a half minutes after induction of anaesthesia TOF-Guard and ParaGraph were started synchronously. Five minutes after induction of anaesthesia rocuronium (0 6 mg.kg^{-1}) was administered Patients were allowed to decuranse spontaneously and TOF-ratio was measured up to 0 9 Comparisons within patients were done using the paired t-test (1° line) and the Wilcoxon signed-rank test (2° line). $P \leq$ 0 05 was considered statistically significant.

Results: Neuromuscular data ($n = 12$) in table 1

Parameter	TOF-Guard minus ParaGraph	p-value
TOF 25% mean (SD)	6 1 (6 9)	0 01
(min) median	6 5	0 01
TOF 50% mean (SD)	5 7 (7 0)	0 02
(min) median	5 5	0 01
TOF 75% mean (SD)	5 0 (8 0)	0 053
(min) median	4.5	0 062
TOF 90% mean (SD)	4 2 (9 1)	0 14
(min) median	4 5	0 15

Conclusion: Both the TOF-Guard and the ParaGraph can be used to determine the level of decuransation and are equal at the relevant clinically assessed end of curarisation (TOF 75% and 90%), but there use should not be interchanged

A.141 An alternative to adductor pollicis muscle in monitoring neuromuscular function: flexor hallucis brevis muscle

H Hepağuşlar, A Önal, F. Ovul *Department of Anesthesiology, Ege University, Izmir, Turkey*

Background & Goal of Study: Neuromuscular monitorization is one of the necessary methods in neurosurgical procedures to optimize the anesthesia management. The hand is sometimes inaccessible in the operating room and another site of neuromuscular monitorization is required. For this reason, it is aimed to compare the responses of both the flexor hallucis brevis muscle and the adductor pollicis muscle to stimulation.

Methods: 11 patients (ASA physical status I–II) who were scheduled for elective neurosurgical procedures in supine position were included to the study after institutional approval and informed consent were obtained. Without premeditation anesthesia was induced with atropin 10 $\mu g\ kg^{-1}$, thiopental 5 mg kg^{-1} and fentanyl 5 $\mu g.kg^{-1}$ and maintained with a mixture of N_2O/O_2/isoflurane Neuromuscular responses were monitored by two TOF-Guards (Biometer, Denmark). One of them measured thumb acceleration and the other measured the large toe plantar acceleration. After stabilization period performed by TOF stimuli (2 Hz) in every 15 seconds with each monitor, 0.1 mg.kg^{-1} IV vecuronium (V) was administered. The onset time, the time to 25% and 75% recovery of T_1, RI, the time to 25% of TOF ratio recovery were measured. Data were analysed with Wilcoxon test; $p < 0.05$ was considered significant.

Results & Discussion: The datum received from this study are shown at the table. (H· Hand, F: Foot)

	Onset (sec)	T_1 25% (min)	T_1 75% (min)	RI (min)	TOF25% (min)
H	135 ± 37	39 9 ± 18	58 4 ± 24	18.4 ± 8	50 5 ± 22
F	155 ± 49*	40 6 ± 15	61 ± 22	20.4 ± 9	49.2 ± 21

Values are mean ± SD *p < 0 05

Besides the onset time there were no significant differences among the groups. Sopher et al (2) found similar results by electromyography.

Conclusion: We conclude that foot can be used alternatively for clinical monitoring of neuromuscular function, especially in neuroanesthesia.

A.142 Computer-controlled infusion of non-depolarising muscle relaxants using an adaptive neural network

G. Geldner, U Schwarz, J. Romeiser, M Lendl, M Georgieff. *Univ.-Klinik für Anaesthesiologie Ulm, Germany*

The invention of modern short-acting drugs allows new forms of anesthesia. Goal of this study was to optimize muscle- relaxation by using a closed- loop-system to apply non- depolarising muscle- relaxants

First of all was to build the hardware- requirements to get reliable maesurements. We used a DATEX AS/3 monitor, which has an integrated NMT-module (NMT = Neuromuscular-transmission) For drug-infusion a GRASEBY 3500- syringe-pump was used. There was also built a software to collect data, which was set up to a laptop-pc usual in the trade.

In the first phase we collected data of 20 ASA I or II-patients undergoing general anesthesia. For induction we applied fentanyl and propofol. Propofol was used as target- controlled- infusion (TCI) at a level of among 2.0 and 3.5 μg/ml. The application of mivacurium was controlled by hand targeted at T1-ratio among 1 and 5 percent The TOF was monitored every 12 seconds

Because of variable sensibility there is no possibility to build a linear function that describes the effect of mivacurium-infusion That is the main problem of control engineering. In the past there were some efforts to solve this problem by using a rule-based fuzzy-controller. Our point of departure was to build an adaptive neural network trained by the collected data. The advantage of neural networks is the absence of fixed rules and the possibility of using the system with various drugs. The disadvantage is the "non-transparency" of the system.

The input for our system are the following measurements:

- quantity and infusion- rate of the initial bolus
- T1 = time to complete relaxation
- T2 = recovering time to a T1-ratio >0
- T1-ratio and infusion-rates of the past 2 minutes

At present the neural network is used as predictor and decision- support-system. The system is able to predict T1-ratio and offers suggestions for controlling infusion-rates to reach a prescribed T1 ratio. The possibility of automatic infusion- control is already implemented

At present a final statistical evaluation is not possible. We collect data in the same way as in the first phase The available data show clear the superiority of the system in comparison with infusion-control by hand.

The system is able to reduce the middle consumption of mivacurium about 20 percent. Trends show also a lower variation of infusion- rates and more steadyness of muscle- relaxation. In principle the system is working well and reliable Technical problems result from duration of anesthesia connected with a deterioration of measuring-conditions after 3 hours. Our attention is directed to correct this unreliability.

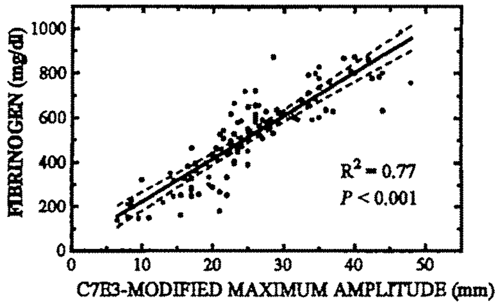
A.143 C7E3-modified thromboelastography predicts plasma fibrinogen concentrations in cardiac patients

O.P. Panzer[1], S C. Kettner[12], S A. Kozek[1], F.A. Seibt[1], J Kofler[3], B. Stoiser[3], G J Locker[3], M. Zimpfer[12]. *[1] Department of Anesthesiology and General Intensive Care; [2] Ludwig Boltzmann Institute of Clinical Anesthesiology and Intensive Care; [3] Department for Internal Medicine, University of Vienna, Austria*

Introducton: Bleeding complications after cardiac surgery can require transfusion of blood components to maintain adequate coagulation. Rapid assessment of coagulation abnormalities is therefore essential. Thrombelastography (TEG) correlates with blood loss after cardiopulmonary bypass and can help to guide transfusion therapy (1). The maximum amplitude (MA) of TEG measures maximal clot strength, which is dependent on fibrinogen level and platelet function (2) Decrease of MA can indicate either fibrinogen deficiency or platelet dysfunction. C7E3-fab, an antibody fragment which binds to platelet glycoprotein IIb/IIIa, inhibits platelet function. Thus, c7E3-modified MA may depend mainly on fibrinogen level.

Methods: With local Ethics Committee approval and informed consent, 37 patients undergoing cardiac surgery with the use of cardiopulmonary bypass were included in this study. Blood samples (102) were obtained perioperatively and c7E3-modified MA was correlated with plasma fibrinogen level. Data were analysed by regression analysis, alpha was set at 0.05 for statistical significance.

Results: C7E3-modified MA correlated significantly with plasma fibrinogen levels (Figure).



Conclusion: Our results show that c7E3-modified MA correlates significantly with plasma fibrinogen levels. Thus, c7E3-modified-TEG could provide a rational guide in hemostatic therapy

A.144 Cross-sectional area of the internal jugular veins: ultrasound comparison between sides and correlation with anthropometric parameters

G.R. de Oliveira Filho, C.R de Oliveira *Departments of Anaesthesiology and Ultrasonography, University Hospital, UFSC, Florianópolis, SC; Hospital Sagrada Família, Itapiranga, SC, Brazil*

Background and Goal of Study: The right internal jugular vein (RIJV) is preferred for central venous, and pulmonary artery catheterization. Left internal jugular vein (LIJV) may be preferable in situations such as right neck surgery, severe right carotid stenosis or documented plaque, or inability to puncture RIJV. LIJV has been shown to have smaller cross sectional area (CSA) and distend less than the RIJV under both Tredenlenburg position and Valsalva manoeuvre(1) This study aimed to compare CSA of both internal jugular veins (IJV) before and during Valsalva manoeuvre in healthy volunteers and to correlate these findings with anthropometric parameters

Materials & Methods: Two hundred consenting adults (M/F: 107/93, 31.36 ± 15.61 years old), were prospectively enrolled, with IRB approval. Body weight, height, body mass index (BMI), sternomastoid distance, neck circumference at the level of the cricoid cartilage and xiphocostal angle were measured Luminal CSA of both IJVs were measured with 2-dimensional, multifrequential (5–10 MHz) linear surface ultrasound at the level of the cricoid cartilage. CSA was determined by planimetry during quiet breathing (control) and after 5 seconds on Valsalva manoeuvre (Valsalva), with subjects lying supine, with the head in neutral position Mann-Whitney U and Wilcoxon matched pairs tests were used as appropriate. Spearman R were calculated between each CSA measurement and the anthropometric variables.

Results & Discussion: In 125 subjects (62.5%), CSA of the RIJV was larger than that of the LIJV, in control measurements. The opposite was observed in the remaining 75 subjects (37.5%). No significant differences in anthropometric parameters were observed between these two subsets. During Valsalva manoeuvre, CSA of the RIJV was larger than the left in 147 subjects (73.5%), smaller in 51 (25.5%) and of the same size in 2 (1%). Small or non-significant correlation coefficients (Spearman R = 0.15 to 0.24) were observed between CSA of both IJVs and anthropometric parameters.

Table 1 CSA and CSA increase during Valsalva manoeuvre of both IJVs [median (lower, upper quartiles)]

	RIJV	LIJV
Control (cm^2)	1.33 (0.92, 1.78)*	1.04 (0.72, 1.49)
Valsalva (cm^2)	2.42 (1.87, 3.57)*	1.81 (1.18, 2.38)
Increase (%)	89 (49, 144)*	61 (23, 106)

* = $p < 0.05$ between sides

Conclusions: Since CSA of the right IJV is more frequently larger than CSA of the left IJV and anthropometric parameters are useless to predict CSA of internal jugular veins, right IJV should be firstly chosen, for central venous access. Moreover, since individual anatomy is unpredictable, ultrasound examination or guidance may be helpful during internal jugular veins cannulation.

A.145 Percutaneous catheterization of the internal jugular vein: original approach

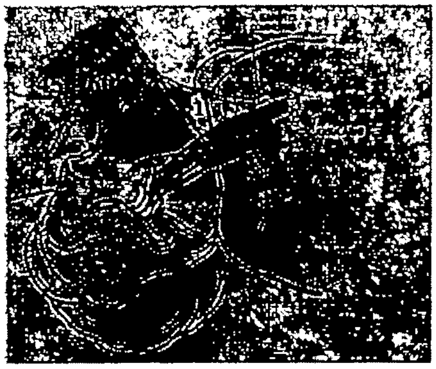
P. Stevanović, M. Kaluđerović, M. Plazinčić. *KBC "Dr D. Mišović", Anaesthesiology and Reanimatology Clinic, Belgrade, Yugoslavia*

Choosing one of the techniques for finding the internal jugular vein is by all means an individual matter. However, there are differences in their successfulness and complications which can occur. We have developed a new, original approach for percutaneous puncture of the internal jugular vein using new, easily visible anatomical orienting points.

During a three-year period, percutaneous cannulation of **i.j.v.** have been performed in this way in 110 patients ranging from 22 to 84 years of age. There were 63 male and 47 female patients. All of them underwent major abdominal operations

Orientation of the puncture site is performed by inspection and by palpation. The most striking point on the front side of the neck is Adam's apple (laryngeal prominence). That is the orienting **point 1.** The mastoid process can be easily palpated behind the auricle. That is the orienting **point 2.** The clavicle and sternum junction is the orienting **point 3.** The point where the middle and the medial thirds of the clavicle unite is the orienting **point 4.** A horizontal line is drawn through the point 1. *The place where it crosses the line which connects the points 2 and 3 is the place where to puncture the internal jugular vein.* The needle is pointed towards the lateral third of the distance between the points 3 and 4, and the skin is penetrated at an angle of 45°–60° in regard to the horizontal plane (Fig.).

Catheter placement was unsuccessful in only 2 cases out of total number (110) of patients. The success percentage of 98.18% achieved. The first attempt successfulness was 86.36% (95 patients) in our series. We have cannulated the vein at the second attempt in 8.18% (9 patients), and in 3.64% (4 patients) we have not done it until the third try. The average depth of vein identification was 1.85–2.85 cm. The patients whose carotid arteries have been punctured at the third try represent the two (1.82%) unsuccessful cannulation attempts



Based on our results, we may draw a conclusion that the i.j.v. puncture technique which we established and applied to the described series of patients is simple to perform, effective and, first of all, safe for the patient.

A.146 Factors affecting guide wire position during central venous catheter placement

H.A McLure, J. Filshie, R. Craig *The Royal Marsden Hospital, London, UK*

Background: At the Royal Marsden Hospital over 1000 long term tunnelled central venous catheters (CVC) are inserted annually for treatment of cancer. A Seldinger technique with radiological imaging allows early detection of guide wire malposition, avoiding reinsertion of a new catheter with attendant costs and risks. Guide wire malposition may be related to grade of operator, patient factors or approach.

Methods: 1104 consecutive infraclavicular CVC insertion records were reviewed, noting initial guide wire direction, operator grade, patient details and approach. Data were analysed using ANOVA and Fisher's exact test where appropriate. A p value < 0.05 was considered significant

Results: On initial placement 8.5% of guide wires were malpositioned. Younger age ($p < 0.0001$) and left sided approach ($p = 0.017$) were significantly associated with guidewire passage across the chest.

Results summarised in table

	Guide wire direction		
	SVC/Right atrium	Contralateral brachiocephal vein	Ipsilateral jugular vein
Numbers (%)	1010 (91.5)	45 (4.1)	49 (4.4)
Male/Female	587/423	29/16	24/25
Weight (kg. mean (range))	69.3 (25–135)	66.4 (29–102)	64.4 (26–100)
Age (yrs; median (range))	57 (10–85)	$33^{\dagger}$ (10–79)	56 (12–77)
Left sided lines (% Left lines)	182 (87.1)	$15^{\dagger}$ (7.2)	12 (5.7)
Mediastinal disease (% of med. dis)	77 (86.5)	4 (4.5)	$8^{\ddagger}$ (9)
Non-Consultant operator (%)	564 (55.8)	20 (44.4)	32 (65.3)

$^{\dagger}p < 0.05$, $^{\ddagger}p = 0.05$

Discussion: Risk groups for malposition include younger patients, or those having left sided CVCs inserted. Age related differences in vessel elasticity, and angle of approach from the brachiocephalic vein into the superior vena cava may cause the guide wire to pass across the chest. In conclusion, image intensifier control is important, particularly if there are other risk factors for central venous cannulation.

A.147 When must we stop subclavian vein cannulation attempts?

J.-Y. Lefrant, L. Muller, J.-L. Pandolfi, S. Bouges, G. Saissi, J.-J. Eledjam. *Fédération d'Anesthésie-Réanimation et de l'Urgence, Département d'Information Médicale, CHU Nîmes, 5 rue Hoche, 30 029 Nîmes cedex, France*

Background & Goal of Study: Failures and complications rates of subclavian vein cannulation (SVC) are about 15 to 20% [1]. SVC with several attempts of venipuncture leads to more complications [1]. The aim of the study was to record the rates of complications and of failures according to the number of venipunctures.

Materials & Methods: Since 1993, patients requiring a SVC were included into the study. Were excluded patients with serious coagulopathy, patients in whom a SVC was already inserted or attempted. Failures and immediate complications (arterial puncture, pneumothorax, wrong position of catheter tip), the number of venipunctures per SVC and the time for SVC (between the 1rst attempt of venipuncture to the guide-wire placement) were recorded or measured. Failures and immediate complications were compared between catheterized SVC at the 1^{st}, 2^{nd}, 3^{rd} or after more than 3 attempts. Results are expressed in mean ± SD or median (with 5th and 95th) values. Statistical analysis used chi-square test ± Fisher exact test and Kruskal-wallis test. A p value < 0.05 was considered as significant

Results and Discussion: 506 patients (age = 65 ± 17 years) were included. Failures, complications and the time for SVC are shown in Table 1

Table 1

	1 VP (n = 341)	2 VP (n = 74)	3 VP (n = 32)	≥4 VP (n = 59)
Complications or failures	14 (4%)	15* (20%)	15* (47%)	43* (73%)
Failures	2 (0.6%)	2 (2.7%)	6* (19%)	24* (41%)
Complications in successful SVC	13 (3.8%)	14* (19%)	13* (41%)	32* (54%)
Art punctures	1 (0.3%)	5* (6.8%)	11* (34%)	23* (39%)
Pneumothor aces	1 (0.3%)	6* (8.1%)	2* (6.3%)	6* (10.2%)
Wrong position	11 (3%)	3 (4%)	1 (3%)	3 (5%)
Time for SVC (s)	22 (10–86)	61* (30–200)	192* (60–900)	330* (155–1200)

VP = venipuncture. * = $p < 0.05$ compared to 1 VP

When SVC were achieved in 1 venipuncture, failures and complications were rare, largely represented by wrong position of catheter tip. When more than 1 venipuncture were needed, failures and complications rates increased At the 3rd venipuncture, a failure and/or a complication were in nearly 1 case over 2.

Conclusion: After 2 failed venipunctures, the procedure for SVC has to be stopped because complications and failure rates are about 50%.

A.148 Knowledge about pulse oximetry among residents and nurses

H. Bilgin, O Kutlay, D Cevheroğlu, G. Korfalı. ,

Background and Goal of Study: Pulse oximetry is used increasingly in operating theatres, recovery rooms and intensive care units (1, 2) The goal of the study is to evaluate the knowledge of medical persons who are using pulse oximetry and their ability to interpret the information.

Materials and Methods: A 17 item multiple choise questionnaire (7 demographic, 10 knowledge) was developed about pulse oximetry. Interviews were completed in the same day for to prevent the respondents having the chance to revise their knowledge of pulse oximetry 12 residents in anesthesiology and 44 intensive care nurses ansuered this questionnaire. Questions were related about the theory behind the pulse oximetry, factors affecting readings, normal ranges in adult and childhood, units of measure of SpO_2 and PaO_2, relationship between SpO_2 and PaO_2, reading if cardiac arrest and respiratory arrest ensues Responses were scored against standart answers from reference texts.

Results and Discussion: Although most of the participants (98%) use pulse oximetry regularly in their daily work, 70% of the participants felt themselves enough confident about pulse oximetry Only 14% of the participants believed that they had adequate training It is considered that 86% of the participants do not understand how a pulse oximeter works. But 75% of the participants answered correctly what does pulse oximeter measure.

Conclusion: The results revealed that there is general lack of knowledge about pulse oximetry

We suggest that residency programs and nursing postgraduate programs should place more amphasis on teaching the principles of pulse oximetry and should be repeated at regular intervals.

A.149 The advantage of preadmission anaesthesia consultation: results of a randomized controlled study

M. Blanc-Jouvan[1], D. Long[1], A. Mercatello[2], M P Benoit[1], M. Khadraoui[2], R. Chacornac[3], C. Némoz[4], M. Gaydarova[4], J P. Boissel[4], J.F. Moskovtchenko[1]. *[1]D.A.R· Hôpital E. Herriot, [2]Hôpital de la Croix-Rousse; [3]Hôpital Neurologique; [4]Service de Pharmacologie Clinique, av Lacassagne, Lyon, France*

Background: Anaesthesia consultation may take place in the department the day before the operation, or previously and be conducted well before hospitalisation In the absence of PAC, surgical operations can be delayed or cancelled through inadequate preoperative assessment and preparation The aim of this study was to evaluate the advantage of PAC compared with the usual practice, in a teaching hospital.

Methods: After approval by the Ethics Committee, 296 consenting patients scheduided for an urologic, ophtalmologic, or otorhinolaryngologic procedure, were included The trial was prospective, controlled, and randomised by random assignment of one of the following strategies: preadmission anaesthesia consultation (PAC group), or preanaesthetic visit the day before the operation (control group or PV group). The primary outcome was the length of preoperative hospitalisation. The secondary outcomes were the number of delayed operations and patient satisfaction

Table I Preoperative hospitalization duration (days)

	Group 1	Group 2	p (test t)
Population	139	144	
Urologic	2 04	2.38	0 05
Ophtalmologic	2 04	2 65	0 007
ORL	2	2 07	0.66
Total	2 04 ± 0 07	2 4 ± 0 09	0 0016

Table II Postponement of surgical procedures

	Group 1	Group 2	p
Medical postponement	2	13	<0 01
Chirurgical postponement	4	0	
total	6	13	0 17

Results: 139 patients underwent preoperative anesthetic and surgical assessment as outpatients, and 144 entered hospital on the day before surgery and underwent anaesthetic assessment as inpatients. Both groups were comparable for age, sex, surgical procedure. Table I shows the preoperative hospitalization duration. Table II shows the number of postponement of surgical procedures 85% of the group 1 patients thought that the preoperative assessment clinic put them a usefull inconvenience, and 82% thought that the preoperative assessment clinic reduced preperative anxiety.

Conclusion: PAC allows reduction of the preoperative hospitalisation period and the number of operation postponements from medical causes Early evaluation by the anesthesiologist is not a constraint for a majority of patients

A.150 Evaluation of the degree of knowledge about difficult intubation

P. Avarguès[1], A M Cros[1], R. Shehata[1], V. Daucourt[2], P Michel[2] *[1]DAR IV; [2]Service d'information médicale, Hôpital, Pellegrin, 33076 Bordeaux cedex, France*

Goal of the Study: To evaluate the level of knowledge of anaesthetists in terms of difficult intubation (DI), anticipation and management of DI using different techniques.

Material & Methods: A survey was carried out in three representative regions in France. One hundred anaesthetists were randomly selected in each region; each of them were sent a questionnaire The first part concerned characteristics of the practitioner i,e. age, sex, years of practice, condition of exercice (university, regional hospital or private practice), number of intubations and number of DI/year. The second part assessed knowledge about DI: predictive signs, different techniques or devices, managements wether predicted or not. The last part was a survey on the actual need for intubation teaching. fibrescopic intubation, LMA, transtracheal ventilation, retrograde intubation, light stylet. After one month anaesthetists who did not reply were sent the questionnaire again. Then they were called by phone one month later if no reply has been sent.

Results: Two hundred and twenty-one questionnaires were sent back (74%)· 32% of anaesthetists worked in a university hospital, 28% in a regional hospital and 29.9% in a private practice. Five predictive signs were selected: mouth opening (93.1%), cervical mobility (92 7%), retrognathia (91.8%), Mallampati class (81%) and short neck (80 1%). In the practice, the commonest signs searched for were different than those selected: mouth opening (70%), neck mobility (63%), Mallampati class (60 1%), short neck (53 8%) and retrognathia (53 8%). The five techniques commonly used for difficult airway management were· blind nasal intubation (83.7%), LMA (81.9%), fibrescopy (53.3%), stylet (39 8%), intubation with LMA (29.4%) In case of predicted DI the techniques used are fibrescopy (43%), blind nasal intubation (27 6%) and LMA (11.8%). Awake intubation 48.3% under GA (50%) with or without muscle relaxants If DI is unpredicted the first technique used is blind nasal intubation (40 3%) then LMA (25.3%)

Discussion and Conclusion: LMA is very often used and most French anaesthetists are familar with it This study done before the publication of the expert conference on DI showed that workshops were needed for teaching purposes as well as for early detection and management of DI, since blind nasal intubation is still the most commonly used amongst anaesthetists.

A.151 Difficult intubation: evaluation of the impact of the French expert conference

P Avarguès[1], A.M. Cros[1], R. Shehata[1], P. Maurette[2] *[1]DAR IV; [2]DAR III, Hôpital Pellegrin 33076 Bordeaux cedex, France*

Goal of the Study: To evaluate the impact of the French expert conference (conf) on difficult intubation (DI) (1).

Material & Methods: This study was carried out in 3 regions of France, by mean of a questionnaire (quest) wich comprised 4 parts· 1) the characteristics of the anesthetist (A); 2) the predictive signs of DI; 3) the techniques used; 4) the teaching methods preferences. The quest was sent to 100 anaesthetists randomly selected in each region, 3 months before the publication of the conf (group 1, n = 300) Three months after the publication of conf, another 100 randomly selected anesthetists, in each region, were then given the same quest and added to it a survey on the impact of the conf on the daily practice (group 2, n = 300). Half of them received the abstract of the conf two weeks before (group 2b). The anaesthetists who did not receive it were considered as group 2a. Chi^2 of Pearson and Fisher's exact method were used ($p < 0.05$ significant).

Results: 90.8% of answers were received from the group 1 and 79.3% from the group 2 The groups were not different for age, sex, practice status, level of the theoritical background and level of practice. In group 2b, 80% of the anaesthetits had read the conf and in the group 2A 65.9%, but the answer concerning the predictive signs and the anticipation of the DI were not statiscally different. On the other hand, there was a better knowledge of the material and methods: combitube (p = 0.02), light-wand stylet (p = 0 003), and bullard laryngoscopes (p = 0.004) was found. The anaesthetists from group 2b claim being more aware to the predictive signs (p = 0 006)

Discussion and Conclusion: The publication of the results of the experts conference did not significantly modify the way of the daily management of DI. There is only a better knowledge of the material used It is obvious that the practical seminars and workshops are mandatory for reinforcement of the impact of this conf.

A.152 Physical treatment of fever

R Lenhardt[1], C H Negishi[1], Jin-Soo Kim[1], D.I Sessler[1,2]. *Departments of Anesthesia, [1] University of California, San Francisco, CA, 94143-0648, USA, [2] University of Vienna, Vienna, Austria*

Background: Fever is by far the most common thermal perturbation In febrile patients, heart rate and metabolic stress can be substantial Consequently, fever in hospitalized patients is usually treated aggressively. When patients fail to respond adequately to anti-pyretic administration, surface cooling is a common secondary treatment Thermoregulatory theory[1], however, suggests that surface cooling in febrile patients will trigger vasoconstriction and shivering, and produce marked thermal discomfort. Furthermore, core temperature may actually *increase* to compensate for skin cooling In contrast, surface warming is likely to reduce vasoconstriction and shivering, increase thermal comfort, and may even – paradoxically – reduce core temperature. Accordingly, we tested the hypothesis that active warming is superior to active cooling in the treatment of fever.

Methods: With IRB approval we studied nine healthy male volunteers. They were given a 30 KU/kg bolus of recombinant Interleukin II, with an additional 70 KU/kg bolus two hours later. Each volunteer participated on three randomly-assigned days: 1) a single cotton blanket, 2) skin-surface cooling (15°C); or, 3) skin-surface warming (≈40°C). Thermal management continued for five hours, starting one hour after the second dose of IL-II. Core temperatures were recorded from the tympanic membrane Thermoregulatory vasoconstriction was evaluated using forearm minus fingertip, skin-temperature gradients; shivering was evaluated with indirect calorimetry and qualitatively. Integrated and peak temperatures and mean oxygen consumption during the treatment period were compared using repeated measures of ANOVA and Scheffé's F-tests Data are presented as means ± SDs, $P < 0.05$ was considered significant

Results: Peak core temperatures were 38.4 ± 0.5°C on the control day, 38.5 ± 0.4°C on the warming day and 38.1 ± 0.5°C on the cooling day Integrated core temperatures on the control day were 6.0 ± 1.6°C h, and on the warming day 6 4 ± 1 2°C·h, and on the cooling day 5.7 ± 2.2°C·h, values that did not differ significantly Mean oxygen consumption on the control day was 334 ± 45 ml/min, on the warming day 312 ± 31 ml/min, and on the cooling day 434 ± 44 ml/min Thus, mean oxygen consumption differed significantly between control and cooling day by about 30%. Duration of vasoconstriction was similar during control and cooling day, being 244 ± 85 min respectively 268 ± 65 min, whereas it was 159 ± 89 min on the warming day. Shivering was a consistent feature on the cooling day, but it was infrequent on the control day with no shivering on the warming day. Shivering on the cooling day lasted for 229 ± 35 minutes, but was only seen for 33 ± 11 minutes on the control day in three individuals. Pyrogen administration. However, it increases oxygen consumption considerably. In contrast, warming during fever virtually obliterates shivering and reduces duration of vasoconstriction significantly. Surface cooling thus appears to be a poor treatment for fever – at least in patients who are not heavily sedated or paralyzed.

A.153 Influence of paralysis on the development of fever during isoflurane anaesthesia

C.H Negishi[1], R. Lenhardt[1], J -S. Kim[1], D I. Sessler[1,2]. *Departments of Anesthesia; [1] University of California, San Francisco, CA, 94143-0648, USA; [2] University of Vienna, Vienna, Austria*

Background: Fever occurs during anesthesia in response to infectious or non-infectious etiologies. However, intraoperative fever is relatively rare considering how often pyrogenic etiologies are likely to be present, and how common fever is postoperatively. This low incidence in part results from dose-dependent inhibition of fever by general anesthesia Additionally, paralysis, may also contribute by preventing shivering. We therefore tested the hypothesis that paralysis decreases peak and integrated core temperatures after pyrogenic stimulation, during isoflurane anesthesia

Methods: With IRB approval we studied seven healthy male volunteers They were given 30 KU/kg bolus of recombinant Interleukin II, with an additional 70 KU/kg bolus 90 minutes later. Thirty minutes after the second dose of IL-2, the volunteers were randomly assigned to either 1) paralysis or 2) no muscle relaxants Anesthesia and paralysis continued for six hours. Core temperatures were recorded from the tympanic membrane Thermoregulatory vasoconstriction was evaluated using forearm minus fingertip, skin-temperature gradients, shivering was evaluated with indirect calorimetry and qualitatively. Integrated and peak temperatures and integrated heat production during anesthesia were compared using two-tailed, paired t-tests. Data are presented as means ± SDs; $P < 0.05$ was considered significant.

Results: Core temperature on the unparalyzed day reached a peak of 37.6 ± 0.9°C whereas the peak on the paralyzed day was 37 2 ± 0.6°C Integrated core temperatures on the unparalyzed day were 3.4 ± 3.4°C·h, and on the paralyzed day 2.1 ± 3 1°C·h, thus insignificantly differing by 1 3 ± 2 1°C·h Integrated heat production without muscle relaxant was 4 2 ± 0 4 kcal/kg, with paralysis 3.6 ± 0.4 kcal/kg Thus, integrated heat production differed significantly by 0 7 ± 0.3 kcal/kg over the study period. The onset of fingertip vasoconstriction was similar in both groups, being 2.1 ± 1 hours on the unparalyzed day and 2.2 ± 1.5 hours after induction of anesthesia. Shivering was a consistent feature on the unparalyzed day It started 6 ± 43 minutes after the onset of vasoconstriction and lasted 54 ± 30 minutes

Conclusion: Paralysis does not significantly reduce integrated or peak core temperatures following pyrogen administration. Vasoconstriction thus appears to be the major factor contributing to development of fever during anesthesia.

A.154 Comparative study of tympanic, bladder, oesophageal and pulmonary artery temperature measurement during major abdominal surgery

J.M. Budd, A. Helmy, J.W Freeman. *Queen Elizabeth University Hospital, Birmingham, England*

Background: The maintenance of normothermia during major surgery is now becoming an important goal as the effects of changes in body temperature on peri-operative morbidity are increasingly recognised The most accurate method of core temperature measurement is said to be via a pulmonary artery (PA) catheter but its insertion has inherent risks and large volume transfusion may affect readings [1] In this study we have compared PA temperature measurement with other conventional sites and also with an infra-red (IR) tympanic probe in an attempt to establish an alternative acceptable reflector of core temperature.

Method: 10 patients undergoing orthotopic liver transplantation were studied. PA temperature was monitored with a Baxter thermodilution catheter and oesophageal, bladder and tympanic temperature with Mallinckrodt Mon-a-therm™ temperature probes. An IVAC Corecheck™ IR tympanic monitor was used to obtain intermittent readings from the opposite tympanic membrane. Temperature was recorded from each site at set points during surgery. Agreement between measurements was assessed by comparing mean difference from PA temperature (instrument bias) and standard deviation (SD) of differences (precision).

Results: There was good correlation between PA temperature and the four other sites. oesophagus, r = 0 97, bladder, r = 0 90, tympanic probe, r = 0 85 and tympanic IR, r = 0.96.

Mean difference (±SD) between PA temperature and oesophagus was –0 18 ± 0 2, between PA and bladder –0.15 ± 0.44, between PA and tympanic probe 0.08 ± 0.57 and between PA and tympanic IR –0 53 ± 0 25.

Conclusion: All four sites provided a close estimate of PA temperature with the oesophageal site being the most precise Tympanic IR temperature using the IVAC Corecheck™ provides an accurate, non-invasive method of temperature measurement and is an acceptable reflector of core temperature during major surgery

A.155 Preservation of heat and humidity after 48 hours use of one hygroscopic heat and moisture exchanger

L Thomachot, C. Boisson, F. Michelet, R. Vialet, S Arnaud, C Martin
Hopital Nord, Marseille University, Marseilles, France

Background & Goal of the Study: The aim of this study was to determine whether changing heat and moisture exchangers (HMEs) every 48 hours rather than 24 hours would affect their efficacy to preserve heat and moisture of expiratory gases.

Material & Methods: after randomization, 29 patients were allocated to one of the three following groups Patients in group 1 were ventilated for 24 hours with a HME (Humid-Vent Filter Light, Gibeck, Sweden) Patients

In group 2 were ventilated for 48 hours with the same HME, and patients in group 3 were ventilated for 48 hours with a heated humidifier system (HHS) (Bennet Cascade 2 humidifier). In each patient, during the inspiration phase, the following measurements were performed: peak and mean airway pressures, mean values of temperature, relative and absolute humidity of inspired gases. In each patient, measurements were performed after 24 hours and after 48 hours where appropriate.

Results & Discussion: After 24 h, patients in groups 1 and 2 had similar levels of temperature (30.1 ± 2 7 and 29 2 ± 2 3°C), relative humidity (98.3 ± 3 6 and 99.3 ± 3 4%), and absolute humidity (29.1 ± 2.1 and 29 3 ± 2.4 mg H2O/l). Using the same HME for 48 h rather than 24 h did not affect its technical performances: temperature 24 h: 29.2 ± 2.3°C, 48 h 28.7 ± 1.9°C, relative humidity 24 h: 99.3 ± 3 4%, 48 h· 99.2 ± 1.7%; absolute humidity 24 h: 29.3 ± 2 4 mg H2O/l, 48 h· 28.7 ± 3.1 mg H2O/l.

Conclusion: Changing the HME after 48 h rather than 24 h did not affect its technical performance in terms of heat and water preservation of ventilatory gases.

A.156 Effect of humidification on the incidence of adverse airway events during deepening of anaesthesia with desflurane

J.E. Hall, A.R. Wilkes, E. Wright, S Grundler. *Department of Anaesthetics and Intensive Care Medicine, University of Wales College of Medicine, Cardiff CF4 4XN, Wales, UK*

Background & Goal of Study: Desflurane has a very low blood:gas solubility of 0 42, making it potentially useful in day-case anaesthesia (1). Its use has, however, been hampered by its irritant nature. Van Heerden demonstrated that adverse airway events during induction with isoflurane were reduced by humidifying the gases delivered to patients (2). We therefore investigated whether humidification affected the incidence of adverse airway events during induction with propofol and desflurane.

Materials & Methods: 60 ASA grade 1 and 2 female patients received 3MAC desflurane gradually introduced in N_2O and O_2 (2:1), following preoxygenation and induction with propofol 3 mg.kg^{-1} Gases were delivered through a Bain breathing system. Patients were randomly allocated to receive either low or high humidification using two different breathing system filters (Pall BB25 and DAR Hygrobac S, respectively) in a double blind manner. Adverse airway events (coughing and laryngospasm) were noted. Fisher's Exact Test was used for analysis

Results & Discussion: 58 patients completed the trial, with 29 in each filter group. Overall high humidity did not significantly reduce the incidence of adverse airway events compared to low humidity (10/29 and 17/29, respectively). However, 28/58 patients smoked and these were more likely to suffer adverse airway events than nonsmokers (19/28 and 8/30, respectively, $p <$ 0 05). Nonsmokers with low humidity gas were more likely to suffer adverse airway events compared to high humidity (6/13 and 2/17, respectively, $p < 0.05$). Smokers were more likely to cough than non-smokers (17/28 and 5/30, respectively, $p <$ 0 05), but were equally likely to suffer laryngospasm (6/28 and 5/30, respectively). Overall, the incidence of laryngospasm was reduced in patients receiving gas with a high humidity compared to low (2/29 and 9/29, respectively, $p <$ 0 05).

Conclusions: Anaesthetists should encourage patients to refrain from smoking prior to surgery (3). Breathing system filters with a high moisture ouput reduce the incidence of adverse airway events during deepening of anaesthesia with desflurane in non-smokers

A.157 Failure of warmed insufflation gas to prevent hypothermia during laparoscopic hysterectomies

K. Nelskylä, A. Yli-Hankala, J. Sjöberg, K. Korttila *Dept of Obstetrics and Gynaecology, Helsinki University Central Hospital, Finland*

Background & Goal of Study: Hypotermia is a problem in long laparoscopic operations (1). Warming of the delivered CO_2 insufflation gas may be useful (2). We tested the effectiviness of warmed CO_2 insufflation gas during laparoscopic hysterectomies (LH).

Material and Methods: 37 consenting women with permission of Ethics Committee of the hospital were randomized into heated (37°C; n = 18) and unheated (room temperature, n = 19) CO_2 insufflation groups. Tympanic (t_{tymp}) and skin (t_{skin}) temperatures were recorded preoperatively, in the beginning of anaesthesia and surgery, and every 15 minutes during operation In postanaesthesia care unit t_{tymp}, t_{skin} and shivering were measured at 15 and 75 minutes after extubation. The anaesthesia was standardized sevoflurane- O_2- air after propofol induction. All fluids were warmed.

Results and Discussion: There were no differences in the parameters measured (see Table).

Table Characteristics and temperatures (t°C) Values are 95% confidence intervals for mean

	Heated	Unheated group
Age (years)	43–49	46–50
Used CO_2 gas (l)	100 5–192 2	95 1–145 4
Duration of anaesth (min)	70–83	65–84
Δ t_{tymp} during anesth	– (1.4–0 9)	– (1 0–0 7)
Beginning of anesthesia		
t_{tymp}	36.8–37 2	37 0–37.3
t_{skin}	29 9–31.8	30 7–32 5
Beginning of operation		
t_{tymp}	36.2–36 6	36.4–36 8
t_{skin}	33 2–34 6	34 2–35 2
End of operation		
t_{tymp}	35 6–36 1	36.1–36 4
t_{skin}	33 6–34 6	32 9–34.7

Shivering between the groups did not differ postoperatively. Preanaesthetic values in t_{tymp} were reached at 90 minutes postoperatively. In some patients, the core temperature decreased below 36° C.

Conclusion: In patients undergoing LH, where the duration of anaesthesia was around 75 min, the patients did not benefit from heated gas insufflation.

A.158 Comparison of four forced-air blankets for intraoperative cutaneous warming

Y Camus, E. Delva, Z. Abdelhalim, A Lienhart *Department of Anaesthesia and Intensive Care, Saint-Antoine Universitary Hospital, Paris, France*

Background: Forced-air cutaneous warming is an efficient method for preventing intraoperative hypothermia [1]. Several forced-air warming systems are available today, but a study in unanaesthetized volunteers has shown that they were not equally efficient [2]. The type of the air-blanket appeared to be one of the factors contributing to the difference. The aim of this study was to compare, under clinical conditions, the efficiency of 4 different covers using one common power unit

Material and Methods: 40 adult patients ASA 1 or 2, scheduled for abdominal surgery in a supine position lasting at least 3 hours gave their informed consent to enter the study. They were intraoperatively warmed with a lower-body air b'anket covering the lower limbs. They were randomly assigned to one of four groups according to the type of blanket: Bair Hugger®, Mallinckrodt®, Thermacare®, Warmtouch®. All the blankets were attached to a power unit Bair Hugger 505 set at 43°C. The air blanket was covered with a cotton sheet if recommended by the manufacturer Core temperature (T) was monitored at the tympanic site every 15 minutes. Skin T were registered from 3 sites on the lower limbs Results (mean ± SEM) were compared using t-test and ANOVA.

Results: The four groups did not differ for age (56 ± 2 yr), weight (68 ± 2 kg), and ambient T (20.0 ± 0.1°C) The time courses of core T are shown in the figure. They were no significant differences between the groups until the third hour of anaesthesia. The highest skin T registered was 40°C.

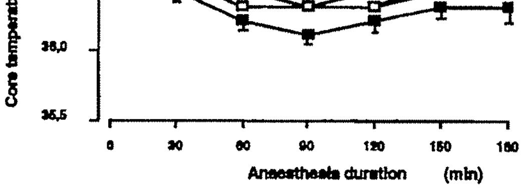

Figure Time course of core temperature during surgery in the four groups No difference between groups

Conclusion: The four forced-air warming blankets evaluated in our study had comparable efficiency under clinical conditions, a result which differs from that observed in volunteers

A.159 Tissue thickness shift detection by a new miniature ultrasound device in anaesthetic practice

W Eichler, J. Schumacher, R. Vogel, K -F. Klotz *Department of Anaesthesiology, Medical University of Lubeck, Germany*

Background and Goal of Study: A new non-invasive ultrasonic miniature device (GDM, Krautkramer GmbH & Co, Hurth, Germany) is available to measure the tissue layer thickness in circumscribed superficial tissue areas where the underlaying bone provides good backwall echos (1). This method could be helpful in anaesthetic practice to guide the fluid therapy and to detect development of tissue edema at an early stage. The superficial tissue thickness (TT) is determined by the renal and cardiac function But patient's positioning and infusion regime influence the parameter. Aim of our study was to get basic data about changes of TT under typical pre-anaesthetic conditions.

Probands, Materials, and Methods: After approval of the study design by the local ethical committee we measured the TT at forehead area in 20 male healthy volunteers (age 24–37 years, body weight 62–94 kg, normal BMI) before and 30 minutes after three procedures (P1–3): P1· change from upright to supine position P2 infusion of 10 ml/kg b w of ringer's solution after achieving a mild hypovolaemia by physical effort (average fluid loss of 508 ml) Haematocrit was evaluated before and after infusion P3: change from supine to 30° head down tilt position. Differences between the measurements were assessed by a Friedman test A $p < 0.05$ was considered significant

Results and Discussion: TT in the probands was 4 30 ± 0.12 mm (mean ± s e.m) In the upright position Procedure P1 lead to an increase of 0 11 ± 0.025 mm Rehydration after a mild hypovolaemia (P2) results in an extention of TT of 0 17 ± 0.06 mm. Mean decrease of the haematocrit was 0.02, which indicates a little overcompensation of fluid deficit. The largest augmentation of TT (0 28 ± 0 051 mm) was seen with the head down positioning (P3) These changes were statistically significant.

Conclusion: By the tested new miniature ultrasound device we could show the dimension of expected increase of TT in typically anaesthetic procedures in healthy probands, namely the change of body position and infusion therapy. This knowledge can be used in studies of volume administration.

A.160 Tissue thickness shift detection by a new miniature ultrasound device during the perioperative period of healthy surgical patients

J. Schumacher, A Engelke, W. Eichler, S. Hagelberg, K -F. Klotz
Department of Anaesthesiology, Medical University of Luebeck, Germany

Background and Goal of the Study: Assessment of patient's perioperative fluid state misses easily available and non-invasive parameters for guidance of fluid therapy Before determining hypovolaemia or overinfusion it is necessary to get basic data of the course of a new parameter in otherwise healthy patients during surgery Aim of the present study was to evaluate changes of tissue thickness (TT) with an easy to handle ultrasound device during the perioperative course of healthy surgical patients under a standardized fluid regimen.

Patients and Methods: After obtaining ethics committee approval we studied 60 ASA 1–2 patients undergoing comparable surgical procedures with no blood loss under general anaesthesia. All patients were starved for a preoperative period of more than 12 hours. After induction of anaesthesia Ringer's solution was continuously infused at a rate of 8 ml/kg b w. for the first 120 min of the operation TT of the forehead skin area was determined the evening before the operation (te), at induction (t0), followed by intervals of 30 min (t30, t60, t90, t120), and after 24 h at the next evening (t24 h) Simultaneously the haematocrit was evaluated Differences between the measurements were assessed by a Friedman test $P < 0.05$ was considered to be significant.

Results and Discussion: Starvation period (te to t0) lead to a significant decrease of mean TT from 5.03 to 4.60 mm and simultaneously the mean haematocrit increased from 36.8 to 37 9%. During the first 90 min of the procedure and standardized infusion therapy the mean TT-value significantly restituted gradually to 5.09 mm. This value kept stable until the end of the observation period (TT at t24 h = 5.05 mm). The haematocrit decreased significantly in the first 30 min to 33 7% and kept stable during the rest of the observation time The marked fluid deficiency of starvation period as well as the continuous refilling by the infusion therapy is well reflected by the evaluated data of peripheral tissue thickness. In contrast to these findings, the intravasal volume remains in a narrow range throughout the operation shown by the unchanged haematocrit.

Conclusions: The results of the present study demonstrate that perioperative changes of TT of the skin can be easily detected with the tested ultrasound device in healthy surgical patients under the test conditions These data could become a rational basis for non-invasive assessment of patient's fluid state

A.161 Anxiety does not alter gastric emptying

A Lydon, J. McGinley, P.F. Duggan, G Shorten *Depts of Anaesthesia and Biochemistry, Cork University Hospital and University College Cork, Ireland*

Background and Goal of the Study: It has been suggested that preoperative anxiety causes a delay in gastric emptying (1, 2) However, previous investigators have not formally quantified anxiety (1), or examined only the effect of anxiety relative to a patient's predisposition to anxiety (2). The objective of this study was to examine the association between anxiety {measured using the Spielberger State Trait Anxiety Inventory (STAI) and Amsterdam Preoperative Anxiety and Information Scale (APAIS)} and gastric emptying.

Material and Methods: The STAI and APAIS scores for 16 ASA 1 or 2 patients were obtained on the morning of surgery Gastric emptying was then measured using the paracetamol absorption technique (3) Four to 10 weeks later, gastric emptying was again measured, and STAI and APAIS scores were obtained. Data were analysed using paired Students t-tests and linear regression

Results and Discussion: STAI anxiety state scores were significantly greater preoperatively than postoperatively (P = 0 004) Within patient comparison of pre- and postoperative measures of gastric emptying {area under the plasma paracetamol concentration/time curve (AUC) and peak paracetomol concentration (Cmax)} demonstrated no difference (P = 0 39 and 0 49 respectively) Linear regression demonstrated no significant association between AUC (P = 0 69) or Cmax (P = 0.48) and the anxiety component of APAIS. These findings suggest that anxiety does not influence gastric emptying. This is in contrast to previous studies (1, 2) A clinical implication of our findings is that the use of anxiolytic premedicants is unlikely to affect the residual gastric volume at induction of anaesthesia, and thus the risk of pulmonary aspiration of gastric contents.

Conclusion: Preoperative anxiety does not alter gastric emptying.

A.162 Laparoscopic surgery of gastro-oesophageal reflux: ECG and enzymatic study

G Boccara, W. Mamoud, C Mann, Y Pouzeratte, P Colson *Department of Anaesthesia, Hopital St-Eloi, Montpellier, France*

Background & Goal of Study: Gastroesophageal reflux is an increasing indication of laparoscopic surgery [1] Specific cardiac implications were rarely reported in literature, except direct cardiac trauma from a laparoscopic instrument [2, 3]. In consequence to one case of postoperative acute myopericarditis, we analyzed perioperative ECG and postoperative myocardial enzymatic modifications following laparoscopic Toupet fundoplication

Materials and Methods: 25 patients ASA 1, scheduled to undergo gastroesophageal reflux laparoscopic surgery (Toupet fundoplication) were prospectively studied General anaesthesia was standardized with penthotal, sufentanyl, isoflurane, atracurium, and 50% N2O ST segment depression (ST > 1 mm, > 1 min, 60 ms J point) analysis was performed in peroperative period Conventional ECG and non specific (CPK, ASAT, ALAT, LDH, myoglobin) and specific (Troponin Ic, CK-MB) enzymatic analysis were measured in blood sample at arrival in postanaesthetic care unit (TO), 4 h (T4) and 24 h (T24) postoperatively Chest radiography was made at arrival in PACU. If perioperative ECG or troponin disturbances occurred with any chest pain, we prescribed also transthoracic echocardiography TTE. Demographic data were expressed as mean ± SD.

Results & Discussion: 9 women and 16 men, aged 54 ± 15 years, weighing 75 ± 10 kg, were studied. Pneumoperitoneum and hospitalization times were respectively 188 ± 55 min (90–280) and 4.0 ± 0 9 days (2–10). Any peroperative ST segment depression was noted, including during hypotensive (BP ≤ 80 mmHg; 3/25 patients) or hypertensive episods (BP ≥ 160 mmHg, 1/25) One case of peroperative subcutaneous emphysema occurred without ST disturbance. Except one case of conversion into laparomy, any peroperative surgical complication was reported In postoperative period, we found 5 patients with negative T in ECG, without ST segment depression but whose 2 presented vagal bradycardial episod and 2 atypical chest pain, without cardiac enzymatic increase and abnormality of segmental ventricular motion or gazeous in pericardium in TTE. Troponin Ic and CK-MB were not increased postoperatively. Significant increase of CPK and LDH occurred in one patient with negative T in ECG at T0 without TEE modification and morbidity. On the other hand, we found 7/25 patients with significant myoglobin increase. Among of them, one presented elevated myoglobin from TO to T24, with a transient dizziness in PACU, and experienced a diaphragmatic rupture in postoperative day 7 Transaminase concentrations were increased (2-fold normal TGO-TGP values) in 12/25 patients. Among these 12 patients, 5 experienced transaminases elevation up 5–10 fold normal values, without postoperative liver failure or cholestasis, but correlated with left hepatic artery ligature.

Conclusion: In this preliminary study of 25 laparoscopic surgical repair of gastro-oesophageal reflux, we did not find peroperative ST and postoperative ECG modification or specific myocardial troponin Ic disturbances. Unexpectedly, incidence of hepatic cytolysis was frequent (48%), and not reported in literature

A.163 Effect of cricoid pressure on gastro-oesophageal reflux

H. Skinner, K Girling, N. Bedforth, R. Mahajan *University Department of Anaesthesia, Queen's Medical Centre and City Hospital, Nottingham, England*

Background and Goal of Study: Cricoid pressure applied at a force of 44 N completely occludes the upper oesophagus to prevent regurgitation of stomach contents into the pharynx, even in the presence of gastro-oesophageal reflux (1). Cricoid pressure has recently been shown to decrease lower oesophageal sphincter tone (2). This decrease was present even at cricoid pressure of 20 N. This finding has important clinical implications The aim of this study is to investigate whether cricoid pressure promotes gastro-oesophageal reflux.

Methods: 15 healthy volunteers were studied after fasting for more than 4 hours Following local anaesthesia to the nostril, a fine bore oesophageal pH catheter was advanced into the stomach and then withdrawn 4–5 cm above the gastro-oesophageal junction. Cricoid pressure was applied for 60 seconds by resting a padded yoke weighing 4.5 kg on the cricoid. Oesophageal pH was recorded with a Digitrapper MD and analysed with Gastrosoft software (Synectics Medical Limited). Recordings were commenced one minute prior to application of cricoid pressure and continued for a minute after the manoeuvre had been completed. A reflux episode was defined as a fall in oesophageal pH to less than 4 (3).

Results and Discussion: The median (range) resting stomach and oesophageal pH were 1 2 (0 8–1.5) and 6.7 (6.0–6.9) respectively In no subject did the oesophageal pH fall below 4 during application of cricoid pressure One subject, after cricoid pressure was relieved, had a swallow related reflux spike lasting 6 seconds. Assuming a binomial distribution, the probability of not detecting an episode of reflux, if the true incidence of reflux during cricoid pressure is 20% or more, is 0.035.

Conclusion: Cricoid pressure is not associated with a significant risk of gastro-oesophageal reflux in awake starved volunteers

A.164 Capnography monitoring in non-intubated patients during recovery from anaesthesia

A Herrera, C. Suan, S Amezcua, M C Perez-Torres, J.C. Luis, M. de las Mulas. *Hospitales Universitarios Virgen del Rocio and Virgen Macarena, Sevilla, Spain*

Background & Goal of the Study: During the last decade, pulse oximetry and capnography have become standard monitoring during anaesthesia. However, capnography is not employed during recovery from anaesthesia, in spite of being theoretically useful, due to the lack of a reliable commercial system for non-intubated patients. The aim of the study is to evaluate continuous capnography monitoring in non-intubated patients in the postanaesthesia care unit (PACU), employing an easy and simple system.

Material & Methods: After informed consent and with a prospective design, 32 ASA I–III patients who underwent abdominal surgery have been studied during recovery from general anaesthesia. Cardiac rate, blood pressure and SpO2 were monitored in all patients. If SpO2 < 95%, the patient was given supplementary oxygen via face mask (FiO2 = 0.4). Continuous capnography monitoring was also established by direct introduction of the sampling tube luer terminal of an infrared monitoring device (Kontron) into the nostril All the parameters and the presence and shape of the capnogram curve were noted every 5 minutes during the first 15 minutes, every 15 minutes during the following 120 minutes and after, every 30 minutes until discharge from the PACU. Arterial gases and capnogram printing were performed simultaneously 30 minutes after the patient arrival at the PACU Apnoea, hypoventilation, and sampling tube obstruction or mobilisation episodes were noted. Data are presented as mean ± standard deviation and have been analysed using the T Student test, a simple correlation analysis, and tests of bias and precision

Results: The duration of monitoring ranged from 130 to 480 minutes (mean 211.71 ± 83 03). There were not statistically significant differences when mean age and the other studied parameters, including PaCO2 and ETCO2 during the first 120 minutes, were compared. Capnogram was defined by the shape of the curve at the moment of the measurement in 67% of all measurements (n = 320) and there were not statistically significant differences between the group that required supplementary oxygen and the group that didn't. There was significant direct correlation (P < 0 01) between ETCO2 and PaCO2 (r = 0.78, bias = 4.8 and precision = 3 34) 13 false apnoea episodes, 8 cases of hypoventilation (ETCO2 > 40 mmHg and/or RR < 8) during the first 15 minutes, and 7 cases more including the following 120 minutes, were detected by audible alarms. Of these hypoventilation episodes, 5 patients also developed hypoxemia (SpO2 < 95%), always after the hypoventilation episode. Seven cases of the luer terminal and/or sampling tube mobilisation and none of obstruction were reported All cases of hypoventilation and three cases of hypoxemia were resolved by stimulating the patient. No patient was disturbed or injured by the introduction of the luer terminal into the nostril

Conclusions: These results about capnography monitoring by direct introduction of the sampling tube luer terminal into the nostril show that. 1) it can be considered an accurate method for capnography monitoring in non-intubated patients, 2) it allows us to detect hypoventilation and apnoea, 3) it neither disturbs nor hurts the patient, it is not easily moveable or obstructed, and 4) it is suitable for long lasting monitoring

A.165 Evaluation of a new colorimetric $ETCO_2$-detector (Colibri) for confirmation of adequate lung ventilation

J. Kofler[1], A. Nikolic[1], C.G Krenn[2], R. Hofbauer[1], P Krafft[2], M Frass[1].
[1] *Intensive Care Unit, Dept. of Internal Medicine I;* [2] *Dept. of Anaesthesiology and Intensive Care Medicine University of Vienna, Austria*

Background and Goal of Study: Capnographic or colorimetric determination of end-tidal CO_2 ($ETCO_2$) is one of the most reliable methods for confirmation of adequate lung ventilation after intubation (1). A new colorimetric device (Colibri, Icor, Bromma, Sweden) overcomes major shortcomings compared to earlier devices (2): It has a faster response to $ETCO_2$-changes, a longer shelf life and it is available in two different sizes (adults and children) The aim of our study was to determine the utility of the Colibri for confirming endotracheal tube position after intubation in children as well as in adults, and to evaluate the device as a monitor during mechanical ventilation

Materials and Methods: Seventeen children (age 2.8 ± 3.7 years, weight 14 ± 15 kg, group 1) and 36 adults (age 58 ± 15 years, weight 74 ± 13 kg, group 2) were included into the study Immediately after intubation the device was attached between endotracheal tube (ETT) and ventilation bag and a first reading was obtained by the investigator. Simultaneously, ETT position was determined by the anaesthesiologist using clinical methods and capnography Any color change from blue ($ETCO_2 < 4$ mmHg) to dark green ($ETCO_2$ 4–10 mmHg), light green ($ETCO_2$ 10–30 mmHg) or yellow ($ETCO_2 > 30$ mmHg) was considered to indicate endotracheal tube placement. The device was left in its place until end of anaesthesia Readings were obtained regularly and compared to capnographic measurements.

Results: All three esophageal tube misplacements in group 2 and one tube dislocation immediately after endotracheal intubation in group 1 were promptly detected by using the Colibri. The devices worked sufficiently during anaesthesia in all but one case (device became wet) In all patients colorimetric readings showed a very good agreement with capnographic measurements.

Conclusions: Colorimetric $ETCO_2$ monitoring using the Colibri is a safe, rapid and simple method for determining endotracheal tube position after intubation in hemodynamically stable patients The Colibri might be used as indicator of $ETCO_2$ during mechanical ventilation when capnography is not available.

A.166 Are colorimetric carbon dioxide detectors reliable over longer periods?

I. Corrigan, A Larsson. *Department of Anesthesia and Intensive Care University Hospital, Lund, Sweden*

Background and Goal of Study: After endotracheal intubation, CO2-detection in exhaled air is important for verifying proper tube placement Recently, disposable colorimetric CO2 detectors have been developed for this purpose Our objective was to investigate whether these detectors are suitable for continuous use over longer periods in endotracheally intubated ventilated patients

Materials and Methods: We studied two colorimetric detectors, the Easycap (Nellcor, USA) and the Colibri CapnoFlex (ICOR, Sweden), prospectively in 20 ventilator-treated intensive care patients (in ten patients the Easycap and in the other ten the Colibri in random order) for a period of 24 hours and compared the detectors every other hour with a calibrated in-stream capnometer (HP, USA) and intermittently with arterial PCO2 from simultaneously drawn arterial blood samples The color of the detector membrane was read by two independent observers Since pilot-tests showed that the function of the detectors was sensitive to humidity, the detectors were attached between an HME (Humi-Vent Filter Light, Gibeck, Sweden) and the Y-piece The CO2-cuvette was placed between the colorimetric detector and the Y-piece

Results and Discussion: One detector in the Easycap group deteriorated after 14 hours, while the other detectors in both groups functioned well over the 24 hours test period The Colibri detects CO2 semiquantitatively in the 0–4% range, and the Easycap in the 0–5% range. Thus, the color shift is maximal at 4 and 5%, respectively This was shown in this study, where the Colibri and the Easycap indicated >4 and >5% end-tidal CO2, respectively, compared with the capnometer which showed 2 7–6 3% (range) when the Colibri was used and 3 6–6.8% when Easycap was used PaCO2 was 3.9–7 6 kPa Both detectors indicated 0% CO2 during inspiration The color change was more difficult to detect with the Easycap than with the Colibri. The Colibri was easier to attach to the endotracheal tube than the angled Easycap but the side-wing Colibri is designed to give an air-leak (0.2–1.5 l/min in our test), which makes it less suitable for prolonged use during inhalation anesthesia

Conclusions: Nineteen of twenty detectors were reliable for end-tidal CO2 detection in periods up to 24 hours. However, they were inexact in the normal end-tidal CO2 range. The Colibri has a better design regarding the reading of the color change, the attachment to the endotracheal tube, a lower dead space and a lighter weight

A.167 Ethanol absorption during operative hysteroscopy

T. Grau, R. Conradi, E Martin. *University of Heidelberg, Department of Anaesthesiology, D-69120 Heidelberg, Germany*

Fluid absorption is a well known phenomena during operative fluid irrigation, but this has not often been described in patients undergoing operative hysteroscopy. The aim of this study was to measure absorpton of alcohol in comparison to other parameters during fluid irrigation.

110 patients were monitored during operative hysteroscopy The irrigation fluid was a Purisole™ solution (Fresenius) containing 2% ethanol General anesthesia was induced with propofol, fentanyl and vecuronium and maintained with isoflurane and nitrous oxide. From the normoventilated Patient endexspiratory alcohol concentrations were measured using an Alkomat 3010™ (Biotest, Dreleich) every 2 minutes. Sodium, haemoglobin and haemodynamic parameters including Cvp were monitored during anesthesia

Results: Operative procedures with fluid irrigation is usually monitored by using measurments of Na, Hb and Cvp Unfortunately these parameters tend to show a wide spread. The information on fluid absorption seems to be improved by nearly online alcohol tracing method In 47 patients no alcohol absorption was detected 45 Patients showed minimal absorption of irrigation fluid (alc endex <0 2‰). In 8 patients we measured endexspiratory alcohol concentrations between 0 2‰–0 4‰ and 10 Patients showed even higher value.

Our results suggest that endexspiratory alcohol measurement could prove to be a fast and save technique to detect fluid overload in patients undergoing operative hysteroscopy

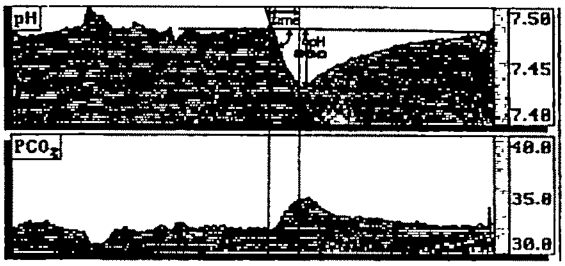
A.168 Effects of rapid blood administration on arterial blood gases continuously monitored

G Vretzakis[1], E Matsandou[1], G Vassiliadou[1], S Koutsias[1], E Ferdi[1], G Vlachogianni[2], D. Papadimitriou[1] [1]*Depts of Anes & Vasc Surgery, "G Gennimates" Hos Thessaloniki,* [2]*ICU "Agios Dimitrios" Hos Thessaloniki, Greece*

During blood transfusion, the low pH of the citrate preservative and the acid accumulation by red cell metabolism may lead to acid-base alterations, usually of transient character. These effects can hardly be detected without a continuous blood gas monitoring system, if administration is rapid For this purpose, this study involves the use of an intra-arterial fiber-optic sensor for continuous blood gas monitoring, based on fluorescent technology [PARATREND 7 (P7) Pfizer Biomedical Sensors], which has been found accurate and reliable at least for PCO_2 and pH

Material & Methods: After protocol approval, patients with preoperative adequate renal function and already monitored with P7 intraoperatively were evaluated for inclusion as follows 1) absence of any respiratory and acid-base disorder 2) rapid blood transfusion not for cardiac output improvement Twelve patients (age 68 2 ± 9.1, ASA I–III were finally included (mainly elective abdominal aortic surgery and radical cystectomies). P7 sensor was introduced through a 20 G radial artery catheter and packed red cells in CPDA-1 were transfused in all cases Blood administration began when acid-base steady state was apparent and under conditions of relative hemodynamic stability. Ventilation was kept unchanged during observation Graphs were processed after planimetry

Results: Transfused blood had a weight of 622.9 ± 285.8 g (mean ± SD), it was stored for 15 1 ± 4 4 days and it was given at a rate of 72 0 ± 9 5 g/min Arterial pH decreased from 7 447 ± 0 023 to 7 385 ± 0 034 ($p < 0\ 001$) while PCO_2 increased from 32.3 ± 1 3 to 36 3 ± 1 8 ($p < 0\ 001$) ΔpH (−0.062 ± 0 024) and ΔPCO_2 (3 9 ± 1.0) showed significant correlation to the weight of transfused blood (r = 0 889 & r = 0.586 respectively) ΔpH showed significant correlation also to the product (weight × days of storage) (r = 0.675). The tangent of pH alteration had a slope of −1.15 ± 0 4 and showed positive but not significant correlation to both the rate and the days of storage (r = 0 518 & r = 0 485) Areas "above" the curve (AAC) for pH and "under" the curve (AUC) for PCO_2 (fig) showed highly significant correlations to the product (weight × days of storage) (r = 0 910 & r = 0.786) Alterations of PO_2, although indicating decreased PAO_2 (in the beginning of the transfusion) and improved ventilation/perfusion ratio (later), where not significant



Discussion: During rapid blood transfusion, although acidosis is mainly of metabolic character, a "coca-cola like effect" is also present Proton load is related to the amount and the storage of blood administered Rapidity of the produced effects is also depending on the rate of infusion Alterations are difficult to detect without a powerful monitoring system The above information may applications in the management of recipients of blood

A.169 Prediction of plasma fibrinogen concentration with native and activated thromboelastography

F A. Seibt, C. Gonano, S C. Kettner, S A. Kozek, O P Panzer, C. Weinstabl, M. Zimpfer *Department of Anesthesiology and General Intensive Care, Ludwig Boltzmann Institute of Clinical Anesthesiology and Intensive Care, University of Vienna, Austria*

Introduction: Thrombelastography (TEG) is a global assessment of hemostatic function, documenting the interaction of platelets with the protein coagulation cascade from the time of the initial fibrin formation, through platelet aggregation, clot strengthening and fibrin cross linkage to eventual clot lysis. The maximum amplitude (MA) of a TEG is dependent upon fibrinogen level and platelet function (1). Recent studies showed a good correlation of plasma fibrinogen level and MA when platelet function is inhibited by c7E3, an antibody fragment which binds to platelet glycoprotein IIb/IIIa (2) As the MA varies with different coagulation activators, such as celite or tissue factor, the correlation of plasma fibrinogen levels with c7E3-modified MA may also vary. Accordingly, we compared native, celite-activated, and tissue factor-activated c7E3-modified MA and plasma fibrinogen levels

Methods: With local Ethics Committee approval, citrated blood samples (20) were obtained from patients, who undergoing elective surgery. c7E3-modified MA was measured in recalcified blood without activation and with activation by celite and tissue factor. Linear regression analysis was performed to determine the correlation between plasma fibrinogen levels and c7E3-modified MA.

Results: Correlation between c7E3-modified MA and plasma fibrinogen levels was higher in activated measurements. Celite-activated measurements correlated better with plasma fibrinogen levels than tissue factor-activated measurements (Table)

Table Correlation of plasma fibrinogen levels and Maximum Amplitude

MA	Adjusted R^2	P-level
Native TEG	0.56	<0.005
Tissue factor TEG	0.69	<0.001
Celite TEG	0.76	<0.001

Conclusion: c7E3-modified MA varies with different coagulation activators. Celite-activated c7E3-modified MA correlates better with plasma fibrinogen levels, than native and tissue-factor-activated c7E3-modified MA. Thus, celite-activated c7E3-modified-TEG may provide a rational guide in transfusion therapy.

A.170 Thromboelastographic coagulation changes after 6% hetastarch administration for the treatment of perioperative hypovolaemia

T J Gan, I J. Welsby, D. Kucmeroski, M Mythen, P S.A Glass.
Department of Anesthesia, Duke University Medical Center, Durham, NC 27710, USA

Background: Currently used hetastarch (HS) solutions can interfere with coagulation. Whether this translates into clinical bleeding is debatable, yet the product label recommends limiting the dose to 20 ml/kg/24 hrs. Standard coagulation assays are poor predictors of coagulopathic bleeding, whereas thromboelastography (TEG) has proven more clinically useful[1]. Thus far, data on the effects of hetastarch on perioperative coagulation have not included TEG changes. Coagulation factor defects result in prolongation of both R and K times with a reduced maximum amplitude (MA) and α-angle, whilst isolated MA and α-angle reduction reflects platelet dysfunction. In contrast, a short R time with an increase MA and α-angle denotes hypercoagulability.

Methods: Following IRB approval and written consent, patients undergoing general surgical, urological and orthopedic procedures with anticipated blood loss of >500 ml entered a protocol to receive 6% hetastarch and packed cells if Hct < 0.25, to treat perioperative hypovolemia. A maintenance fluid of 5 ml/kg/hr lactated Ringers solution was infused. Native blood for paired TEG tracings was drawn on induction (pre) and at skin closure (post). Prior to closure, an objective assessment of clinical oozing was noted

Results: Twenty one patients were enrolled. The volume of colloid infused was 19 ± 3 ml/kg (mean ± SD), 8/21 patients received >20 ml/kg. Estimated blood loss was 608 ± 133 ml. No patients required FFP or PL; six patients received 2–4 units of RBC. There was no clinical oozing at the surgical site and no overall increase in hypocoagulable traces; 10/21 patients were hypercoagulable preoperatively. This is reduced to 8/21 postoperatively. With >20 ml/kg HS traces tended to become normal (Table). The pre operative R, K, MA are 15.7 ± 2.5, 5 ± 1, 66.4 ± 2.9 and post operative R, K and MA are 12.8 ± 2.5, 6.4 ± 0.9, and 58.4 ± 3.4 respectively (mean ± sd). Normal range: {R 19–28, K. 8–13; MA 48–60}. There were no significant differences between any pre and post operative parameters.

	Vol of 6% HS	Type of TEG tracing		
		Normal	Hypocoag	Hpercoag
Preop-op	<20 ml/kg	5/21	1/21	7/21
	>ml/kg	3/21	2/21	3/21
Postp-op	<20 ml/kg	4/21	2/21	7/21
	>20 ml/kg	6/21	1/21	1/21

Conclusions: The volumes of 6% HS used in this study had minimal overall impact on TEG parameters and were not associated with clinical evidence of bleeding, even when exceeding the product label recommendation of <20 ml/kg/24 hours. There is a high incidence of preoperative hypercoagulability among patients presenting for elective, major surgery. This number is reduced after perioperative administration of HS. Further study is needed to show if HS can reduce postoperative hypercoagulability.

A.171 Clinical implications of portopulmonary hypertension in liver transplant patients

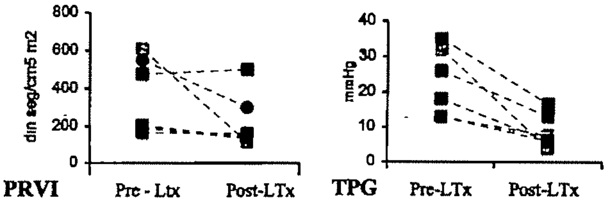
R. Adàlia, P. Taurà, G Martínez-Pallí, E. Zavala, A. Alarcon, J. Gracia.
Department of Anaesthesiology, Hospital Clinic, Barcelona University, Barcelona, Spain

Background: The presence of Portopulmonary Hypertension (PPH) in patients with advanced liver disease often delay in diagnostic process because of symptoms initially are subtle. The perioperative risk of patient with PPH submitted to liver transplant (Ltx) must be recognised. On the other hand, the role of Ltx on PPH remains uncertain.

Aim: To investigate the incidence, clinical characteristics, and the impact of LTx in patients with PPH

Patients and Methods: Twelve of 499 patients (2.4%) submitted to LTx (between 1989 and 1996) fulfilled diagnostic criteria for PPH: elevated mean pulmonary artery pressure (MPAP) (>25 mmHg) and transpulmonary gradient (TPG) (>12 mmHg) with normal pulmonary wedge pressure (PWP), in absence of other cause of secondary pulmonary hypertension. Haemodynamic data were obtained after induction anaesthesia. The clinical history, laboratory data, pulmonary function test of these patients (PPH-Group) were recorded and compared to those of matched patients submitted to Ltx without PPH (Control-Group, n = 40). In 6 patients with PPH, pulmonary haemodynamic follow-up was performed between 18–24 months after LTx. Actuarial survival was also recorded. All data are presented as mean ± SEM. Statistical analysis was performed using analysis of variance (ANOVA) with unpaired-*t*-test

Results: PPH patients showed abnormal, but not significantly higher, alveolar-arterial O_2 gradient (24 ± 8 *vs* 17 ± 5 mmHg, $p = 0.17$), and lower CO diffusing capacity (DLCO) (68 ± 9 *vs* 83 ± 10% pred, $p < 0.05$) than CG. Patients with PPH have an increased cardiac index (CI) (5.2 ± 1.4 *vs* 4.5 ± 1.2 L/min/m², $p < 0.05$), MPAP (34 ± 11 *vs* 17 ± 5, $p < 0.05$), PVRI (398 ± 60 *vs* 135 ± 45 dynes.s.cm^{-5}.m^{-2}, $p < 0.05$), and TPG (26 ± 8 *vs* 6 ± 4 mmHg, $p < 0.05$) when compared to CG. All of them responded to vasodilator drugs decreasing PVRI 20% at least from baseline value. The six PPH patients evaluated after Ltx showed a decrease on MPAP, TPG, PVRI and CI. At 5-yr after Ltx, actuarial survival in PPH patient was 66% while it was 79% in No-PPH patients.



Conclusions: The prevalence of PPH among Ltx candidates is about 2.4%. DLCO should be a useful marker of PPH. In this group of patients with PPH, improvement of pulmonary haemodynamics was observed after LTx.

A.172 Mixed venous oxygen saturation: evolution and correlations during liver transplantation

A. Mora, J Roigé, C Cortés, M Noguer, C. Bosch, V.A. Gancedo
Service of Anaesthesia, General Universitary Hospital Vall d'Hebron, Barcelona, Spain

Background and Goal of Study: Surgery of liver transplantation (LT) developes haemodynamic changes decreasing cardiac output (CO) after venous clamping to exclude the liver. Perioperative monitoring should give information about cardiovascular system and tissue oxygenation. Fiberoptic catheter in pulmonary artery can measure CO and mixed venous oxygen saturation (SvO_2). SvO_2 changes are conditioned with variations in: CO, hemoglobin (Hb), oxygen arterial saturation (SaO_2) and oxygen uptake (VO_2)(1, 2). The aim of this study was to determine SvO_2 evolution and its correlation with their determinants and to evaluate the utility of SvO_2 monitoring during LT.

Material and Methods: Prospective study of 45 patients undergoing LT with piggy-back technique. All patients were managed according to the LT protocol of our institution with respect to anaesthesia, monitoring and transfusion. A fiberoptic catheter (Opticath ®P711, Abbott) in pulmonary artery for continuous SvO_2 monitoring was placed. Measured parameters: cardiac index (CI), VO_2, Hb, SaO_2 and SvO_2. Study phases: T1: before surgery, T2: in hepatectomy phase; T3: anhepatic phase; T4: 5′ after unclamping; T5: neohepatic phase. Data were analysed by ANOVA test ($p < 0.05$) and Pearson lineal correlation coeficient ($p < 0.05$).

Results: Expressed as mean ± SD are showed in table below.

Parameter	T1	T2	T3	T4	T5
SvO_2 (%)	85 82 ± 5 0	85 85 ± 6 4	86 48 ± 7 1	89 79 ± 3 7	87 18 ± 4 0
CI (l min m^2)	4 96 ± 1 4	5 19 ± 1.2	3 89 ± 1 0	6 38 ± 1 4	5 63 ± 1 1
VO_2 (ml/min)	199 ± 58	186 ± 50	152 ± 51	210 ± 56	213 ± 52
Hb (gr 1)	9 85 ± 1 7	9 51 ± 1 6	9 58 ± 1 6	9 30 ± 1 5	9 30 ± 1 3

SvO_2 and CI show a direct correlation in all the study phases (T1 r = 0 52, p = 0 000, T2 r = 0 58, p = 0 000, T3· r = 0 61, p = 0.000; T4 r = 0 45, p = 0 002, T5 r = 0 36, p = 0.016). SvO_2 and VO_2 have an indirect correlation in T2 (r = –0.55, p = 0 000), T3 (r = –0.44, p = 0 004), T4 (r = –0 43, p = 0 003) and T5 (r = –0.43, p = 0.003) No correlation between SvO_2 and Hb levels

Conclusions: SvO_2 is maintained high in all the study phases, including anhepatic phase with a CI decreased (27%) by inferior venous cava partial clamping A decreased VO_2, a stable Hb and SaO_2 without changes, contribute to maintain the values of SvO_2 after clamping A direct correlation is found between SvO_2 and CI in our patients Changes in SvO_2 are explained particularly by changes in CI. SvO_2 is useful as indicator of haemodynamic state in LT

A.173 Endoluminal laser-Doppler measurements of jejunal mucosal perfusion in patients undergoing liver transplantation

E Rønholm[1], L Backman[2], S Friman[2], K.L Karlsen[1], L Mjornsted[2], M Olausson[2], A Åneman [1]*Dept of Anaesthesia & Intensive Care,* [2]*Dept of Surgery, Sahlgrenska University Hospital, S-413 45 Goteborg, Sweden*

Background: Patients undergoing liver transplantation are at risk for developing the multiple organ dysfunction syndrome (MODS) *(1)*. A decreased gastro-intestinal mucosal perfusion has been suggested of pathogenic relevance for the development of MODS *(2)* The aim of this study was to investigate the use of endoluminal laser-Doppler flowmetry for determination of jejunal mucosal perfusion during liver transplantation *(3)*.

Materials and Methods: An endoluminal laser-Doppler catheter was positioned with the tip in the jejunum for continuous measurements of jejunal mucosal perfusion in 10 patients undergoing liver transplantation Central hemodynamic parameters were registered at the end of the dissection phase, at the end of the anhepatic phase, during reperfusion and at the end of surgery.

Results and Discussion: The anhepatic phase was associated with a progressive decrease in jejunal mucosal perfusion and at the end of the anhepatic phase the jejunal mucosal perfusion was reduced to (median [25th/75th]) 49 (40/65)% (p < 0.01) of the dissection phase value At the end of surgery the jejunal mucosal perfusion had increased to 134 (103/158)% (p < 0 01) of the dissection phase jejunal perfusion. The jejunal mucosal perfusion correlated significantly with cardiac index, systemic vascular resistance index and mean arterial pressure However, the pronounced reduction in jejunal mucosal perfusion during the anhepatic phase was out of proportion to the considerable smaller changes in cardiac index and SVR index This indicate that laser-Doppler measurements of gastro-intestinal mucosal perfusion may provide additional information about the gastro-intestinal perfusion, which cannot be estimated from central hemodynamic parameters

Conclusions: Liver transplantation is associated with a decrease in jejunal mucosal perfusion during the anhepatic phase The endoluminal laser-Doppler technique was found to be easily applicable for continuous monitoring of gastro-intestinal perfusion and the technique could prove valuable to detect gastro-intestinal hypoperfusion in patients undergoing liver transplantation.

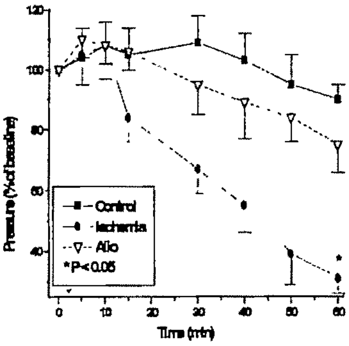
A.174 Xanthine oxidase is directly associated with liver ischaemia-reperfusion-induced remote myocardial dysfunction

A A Weinbroum[1], V Rudick[1], E Hochhauser[2], Y Kluger[3], B A Vidne[2]
[1]*Deps of Anesthesiology & CCM,* [3]*Rabin Div of Trauma, Tel-Aviv, Sourasky Medical Center;* [2]*Cardiothoracic Surgery, Rabin Campus, Israel*

Background and Goals: We previously demonstrated the existence of a direct linkage between cardiac dysfunc-tion and post-ischemia reperfusion in a different organ (Ref) We hypothesized that xanthine oxidase (XO) and generated reactive oxygen species (ROS) are res-ponsible for such damage The present study aimed at confirming this assertion

Materials and Methods: Male Wistar rat livers were isolated and perfused with oxy-genated (37°C) Krebs-Henseleit solution (KH) After 30′ stabilization, livers were either perfused (Control, n = 6), made globally ischemic (Ischemia, n = 6), or made ischemic after being treated with XO oxidoreductase inhibitor allopurinol (Allo, n = 6) for 2 h Paced hearts from other rats were meanwhile isolated and perfused with KH via the ascending aorta (80 mm Hg, modified Langendorff preparation) The 2-h period was followed by a 15′ liver + heart reperfusion phase in which the hepatic effluent was directed into the Langendorff prep The liver was then disconnected and the only heart continued to recirculate alone with the accumulated KH for 45′ more

Results and Discussion: Left ventricular developed pressure (LVDP) in the Ischemia group decreased significantly, measuring ~35% of baseline values at 60′ of reperfusion (fig) Both myocardial velocity of contraction and relaxation (±dP/dt_{max}) decreased by a similar magnitude, as did the coronary flow All parameters remained statistically unchanged in the Controls or Allo groups of hearts. XO activity in the Allo group perfusate was as low as in the Controls but thousands of times higher than in the Ischemia perfusate The low circulating XO activity following the administration of Allo coincided with the absence of remote cardiac dysfunction



Conclusions: XO is directly associated with remote cardiac dysfunction during the period of post-ischemia reperfusion and Allo treatment proved such linkage The precise mechanism(s) by which XO and ROS can alter remote organ homeostasis await further investigation

A.175 Effects of positive end-expiratory pressure on indices of left ventricular diastolic function during laparoscopy

L Dumont[1], V Picard[2], C Mardirosoff[1], C. Dumont[1], M Mattys[1], J Massaut[1] [1]*Department of Anaesthesiology, Brugmann Hospital, Brussels, Belgium;* [2]*Geneva University Hospital, Switzerland*

Background & Goal: CO2 pneumoperitoneum (PN) induces well-known changes in the cardiopulmonary system In presence of hypoxemia, it is sometimes necessary to apply a positive end expiratory pressure (PEEP) to improve arterial oxygenation However, the hemodynamic effect of the peep may worsen the left ventricular diastolic function (LVDF) which is already decreased by PN (1) The aim of this study was to examine the effect of PEEP on indices of LVDF obtained by transesophageal pulse Doppler echocardiography during laparoscopy

Methods: General anaesthesia (propofol, sufentanil) was administered in 10 ASA I–II informed patients scheduled for laparoscopic cholecystectomy Peak velocities of early (E cm/s) and late filling wave (A cm/s) of the transmitral blood flow were measured They were first measured after induction of general anaesthesia with the application of 5 and 10 cm H_2O PEEP, and secondly after PN was raised to 11 mmHg and with the application of 5 and 10 cm H_2O PEEP The E/A ratio and the deceleration time (DT· ms) were calculated as indexes of the LVDF Heart rate (HR beat/min) and blood pressure (BP mmHg) were recorded at the same time

Results and Discussion:

	PN 0 mmHg	PEEP 5 cmH_2O	PEEP 10 cmH_2O	PN 11 mmHg	PN + PEEP 5 cmH_2O	PN + PEEP 10 cmH_2O
BP	78 ± 9	77 ± 10	74 ± 14	97 ± 13*	103 ± 13	106 ± 12
HR	69 ± 11	67 ± 9	68 ± 9	62 ± 8	63 ± 10	64 ± 9
E	59 ± 14	47 ± 11°	44 ± 12°	44 ± 14*	42 ± 12	42 ± 10
A	43 ± 8	41 ± 8	38 ± 8	46 ± 13	46 ± 11	49 ± 10
E/A	1.4 ± 0.5	1.2 ± 0.4#	1.2 ± 0.3#	1 ± 0.5*	1 ± 0.4	0.9 ± 0.3
DT	0.14 ± 0.02	0.16 ± 0.03	0.16 ± 0.05	0.15 ± 0.03	0.15 ± 0.03	0.15 ± 0.05

* PN ANOVA $p < 0.05$ °PEEP ANOVA $p < 0.05$ #PEEP ANOVA $p = 0.057$

After Peep alone and after CO_2 insufflation without PEEP E wave decreased significantly while it does not decrease further significantly when PEEP was applied during the PN. A wave increased after PN but did not change with PEEP. E/A decreased significantly with PN and less significantly ($p = 0.057$) with PEEP alone. There was no changes in DT and HR neither with PN or PEEP. BP was increased after PN but not with PEEP.

Conclusions: These results suggest that LVDF might be reduced as a consequence of a PEEP application and as a consequence of PN. But the effect of PEEP seems to be less important in presence of a PN and does not lead to further significant decrease in E/A ratio.

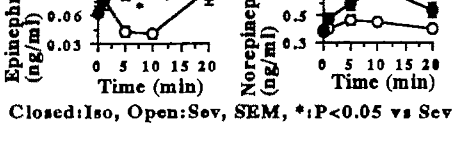
A.176 Haemodynamic and catecholamine responses to a rapid increase in sevoflurane or isoflurane concentration

T. Nishiyama, K. Hanaoka *Department of Anesthesiology, The University of Tokyo, Tokyo, Japan*

Background and Goal of Study: That the effects on sympathetic and parasympathetic nervous system are different between sevoflurane (Sev) and isoflurane (Iso) or not is still controversial. Plasma epinephrine (Ep) and norepinephrine (NEp) concentrations were reported to increase when inhaled Iso concentration was rapidly increased[1]. However, no studies are seen using Sev. The purpose of this study was to compare the hemodynamic and catecholamine responses to rapid increase in inhaled concentration between Sev and Iso.

Materials and Methods: After the approval by our institutional review board and written informed consents, 30 patients scheduled for lower abdominal surgery were randomly divided into two groups; Sev group and Iso group (15 patients each). Anesthesia was induced with midazolam 0.1 mg/kg and thiopental 3 mg/kg and tracheal intubation was facilitated with vecuronium 0.15 mg/kg. Maintenance of anesthesia was done with epidural block using 1% mepivacaine, 67% nitrous oxide in oxygen, and Sev or Iso. When blood pressure and heart rate became stable, Sev or Iso concentration was kept in 0.5 MAC (minimum alveolar concentration, 1 MAC = 2.05% in Sev and 1.15% in Iso, end-tidal concentration measured by Ultima™, Finland) for 15 minutes. Suddenly Sev or Iso concentration (vaporizer setting) was changed to 1.5 MAC and it was kept for 10 minutes, then decreased to 0.5 MAC. Blood pressure (radial artery cannulation), heart rate (electrocardiogram), end-tidal concentration of Sev or Iso, and plasma concentrations of Ep and NEp (high performance liquid chromatography) were measured before, during and after the change of inhaled concentrations. For statistical analysis, chi-square test, unpaired t test, and two-way repeated-measures analysis of variance followed by Fisher's protected least significant difference were used and $p < 0.05$ was considered to be significant.

Results and Discussion: Decrease in blood pressure, increase in heart rate and increase in NEp concentration were significantly greater in Iso group than in Sev group. Ep concentration decreased in Sev group but not in Iso group, which had the significance between the two groups (figure). The sympathetic response to decreased blood pressure might be depressed in Sev anesthesia.



Closed:Iso, Open:Sev, SEM, *:P<0.05 vs Sev

Conclusions: Rapid increase in inhaled concentration of Iso induced sympathetic hyperactivity but that of Sev depressed sympathetic response.

A.177 Which parameters unmask diastolic dysfunction in hypertensives during Valsalva manoeuvre as measured with Doppler sonography?

G. Schuepfer, M. Zuber[1], C. Konrad, C. Fankhauser[1], P. Erne[1] *Institute of Anesthesiology; [1]Cardiology Kantonsspital Lucerne, Suisse*

Introduction: The first consequence of hypertension (HT) is a diastolic dysfunction of the left ventricle (LV) which can be assessed by analysis of the mitral flow pattern (E/A-ratio), the isovolumic relaxation time (IVRT) and the flow velocities in the pulmonary veins e.g. during systole (PV-VTI sys). None of these methods have been reported to be reliable in the absence of morphological changes of the left ventricle.

Patients and Methods: The changes of mitral flow pattern during Valsalva maneuver (VE/VA-ratio) in 5 groups of patients (n = 69) where measured. Patients were classified according to 24 h blood pressure (BP) and dopplersonographic measurements: 1. Normal: Patients with normal left ventricular mass (LVM) and normal BP. 2. Untreated hypertensives with normal LVM and relative wall index (RWI). 3. Hypertensives with normal LVM and high RWI (this reflects remodeling of the LV). 4. Hypertensives with concentric hypertrophy of the LV (abnormal LVM, RWI > 0.45). 5. Hypertensives with excentric left ventricular hypertrophy (abnormal LVM, RWI < 0.45). In all patients E/A-ratio, VE/VA-ratio, the IVRT and PV-VTI sys were assessed. A multiple regression model was generated in order to stratify the patients in the correct groups (1–5) using a stepwise backward elimination procedure.

Results: The E/A-ratio in hypertensives with normal LVM was normal at rest. However with the Valsalva maneuver we were able to show a significant difference between normotensives and untreated hypertensives. The measurement of VE/VA-ratio is sufficient to identify patients with a diastolic dysfunction of the left ventricle ($p < 0.05$), but does not provide sufficient information to stratify them to one of the groups 2–5.

Conclusion: Measurement of VE/VA-ratio using dopplersonography is a clinical useful tool to make a rapid diagnosis of diastolic dysfunction using a single parameter.

A.178 Effect of the insufflating gas on the release of vasopressin during laparoscopy in pigs

C. Mann, G. Boccara, Y. Pouzeratte, F. Navarro, D. Bichet, P. Colson. *Laboratory of Anaesthesiology and Experimental Surgery, Montpellier, France; Hôpital du Sacré-Coeur, Montréal, Canada*

Background & Goal of Study: During CO_2 pneumoperitoneum, haemodynamic changes result from both mechanical and humoral factors. The profile of the increase in vasopressin (VP) parallels the time course of systemic vascular resistances (SVR), suggesting a possible cause and effect relationship (1, 2). However, the trigger for VP release is unknown. We assessed the role of the insufflating gas and, in that way, investigated the relationship between haemodynamic changes and plasma concentration of VP during CO_2 and argon pneumoperitoneum in pigs.

Materials & Methods: 12 pigs (25–30 kg) were anaesthetized with enflurane 1.5%. Argon (n = 6) or CO_2 (n = 6). Pneumoperitoneum was created and maintained constant at 15 mmHg. Ventilation was controlled with a tidal volume of 15 ml/kg at a rate adjusted to obtain $PetCO_2$ of 28–34 mmHg and maintained constant for the remainder of the experiment. Haemodynamic variables were studied by Swan-Ganz and femoral arterial catheterisations. Arterial blood samples were collected before insufflation (Bas), 5 min (In5), 20 min (In20) and 40 min (In40) after the beginning of insufflation, 5 min (Ex5) and 30 min (Ex30) after exsufflation. Plasma lysine VP were measured by radioimmunoassay. Data were analyzed by ANOVA, Student's t test and Spearman's correlation.

Results & Discussion: VP and SVR increased markedly after insufflation of CO_2 pneumoperitoneum (table). There was a significant relationship between these variations ($r = 0.79$, $p < 0.005$). $PetCO_2$ continuously increased throughout the pneumoperitoneum but these variations were not related to changes in VP. VP, SVR and $PetCO_2$ remained stable during argon pneumoperitoneum. Changes in cardiac output and peak airway, right atrial and pulmonary capillary wedge pressures were not different in either group.

		Bas	In5	In20	In40	Ex5	Ex30
CO_2	SVR	2261	2958*	2642	2422	2151	1966
	VP	82	137*	105	93	77	72
Argon	SVR	2100	2252$	2138	2463	2280	2219
	VP	74	81$	68	56	89	60

*$p < 0.05$ versus baseline, \$$p < 0.05$ CO_2 versus argon

Conclusion: In pigs as in humans, the timing of VP release are consistant with a causative action to increase SVR during CO_2 pneumoperitoneum. It seems unlikely that the increase in VP is caused by changes in intrathoracic or intracardiac pressures. We suggest that absorbed CO_2 could be the major stimulus for the VP release during laparoscopy.

A.179 Comparison of gastric-to-arterial ($(P(r\text{-}a)_{CO_2})$) and gastric-to-end tidal ($(P(r\text{-}et)_{CO_2})$) P_{CO_2} gap after cardiac surgery

G. Lebuffe, C Decoene[1], A. Pol[1], B. Vallet *Departments of Anesthesiology II; [1]Cardiovascular Surgery, University Hospital of Lille, France*

Background: Automatized P(r-et)CO_2 as measured with the Tonocap™ is now proposed as a non-invasive marker of gastrointestinal perfusion Increased P(r-et)CO_2 could reflect gastrointestinal hypoperfusion. However, it may be related to either increased P(r-a)CO_2 or increased arterial-to-end tidal PCO_2 gap [P(a-et)CO_2] This study aimed to evaluate in post-cardiac surgery patients, with (Gr1) or without (Gr2) circulatory failure, the significance of increased P(r-et)CO_2.

Methods: 14 patients undergoing elective cardiac surgery were monitored with arterial line and pulmonary artery catheter. Tonocap™ measured end-tidal CO_2 and regional PCO_2 *via* a nasogastric tonometer (Trip™ catheter). Mean arterial pressure (MAP, mmHg), O_2 supply (DO_2, ml/kg.mn), blood lactate (L, mmol/l) and arterial blood were measured every 2 hours during a 12 hour post-operative period The P(r-a)CO_2, P(r-et)CO_2 and P(a-et)CO_2 (mmHg) were calculated. Data (M ± SE) were analyzed using Wilcoxon and Mann-Whitney tests.

Results: In Gr1, as DO_2 failed to increase postoperatively, L, P(r-a)CO_2 and P(r-et)CO_2 increased. P(a-et)CO_2 tended to decrease In Gr2, DO_2 increased, and L, P(r-a)CO_2 and P(r-et)CO_2 tended to remain stable P(a-et)CO_2 tended to decrease as seen in Gr1 (Table).

Conclusion: After cardiac surgery, circulatory inadequacy is associated with a widening in P(r-et)CO_2 suggesting decreased gastrointestinal perfusion This is related to an exclusive increase in P(r-a)CO_2. In this study, the P(r-et)CO_2 gap appears to provide a useful non-invasive index of gastrointestinal perfusion.

A.180 Gastric mucosal hypoperfusion during cardiopulmonary bypass is associated with increased postoperative cardiovascular morbidity

J.C. Sicsic, H. Corbineau[1], V. Louvard, M. Sellin, J. Duranteau, A. Leguerrier[1], Y Logeais[1], C. Ecoffey *Departments of Anaesthesia and intensive care 2; [1]of Cardiac Surgery, CHRU Rennes, France*

Background and Goal of Study: During cardiopulmonary bypass (CPB) gastric mucosal perfusion, assessed by Laser Doppler flowmetry, decreases (1). The hypothesis was that patient with high decrease in gastric mucosal perfusion, and probably inadequacy between oxygen delivery and consumption, may have a postoperative period worsen than patient with a low decrease. In our study we have recorded vasoactive medication consumption to treat hypotension or low cardiac index in post operative period.

Methods: The study was conducted in 43 patients during elective cardiac surgery It was a prospective descriptive study. After general anaesthesia, a pulmonary artery catheter (Baxter®) and the gastric Laser Doppler probe (probe 424, Perimed®) was inserted. The Laser Doppler signal is proportional to the number of red blood cells moving in the measured volume and the mean velocity of the cells. The group high decrease was defined as gastric perfusion less than 50% (100% was pre CPB value) and the group low decrease was defined as gastric perfusion more than 50% during CPB. CPB was managed with a non pulsatile flow at 2.4 L/min/m² with a MAP between 60 and 90 mmHg in moderate hypothermia (30–32°C) Data were recorded in postoperative period 1) cardiac index at admission in ICU, 2) need for vasoactive medication to treat hypotension or low cardiac output (dopamine more than 3 μg/kg/min, dobutamine more than 3 μg/kg/min, norepinephrine, epinephrine), 3) time to intensive care unit (ICU) discharge.

Results: Results are expressed in the table

	High decrease	Low decrease	*P*
Gastric Perfusion at 30 min CPB (%)	40 ± 13	$72 \pm 14^{*}$	<0.001
Cardiac index (L/min/m²)	2.1 ± 0.2	$2.7 \pm 0.5^{*}$	0.02
Vasoactive med (n)	13/20	5/23*	<0.001
ICU discharge (days)	3.6 ± 1.6	3.2 ± 1.5	0.12

Conclusion: Results of our study suggested that patient who have a high gastric hypoperfusion during CPB have a greater cardiovascular morbidity during the postoperative period These major hypoperfusion might be associated with gastric mucosal injury

A.181 Increased gastric-to-arterial P_{CO_2} gap ($(P(r\text{-}a)_{CO_2})$) predicts occurrence of circulatory failure after cardiac surgery

G. Lebuffe, C Decoene[1], A. Pol[1], B. Vallet *Departments of Anesthesiology II and [1]Cardiovascular Surgery. University Hospital of Lille, France*

Background: P(r-a)CO_2 has been proposed as a marker of gastrointestinal perfusion adequacy The aim of the study was to compare, retrospectively, P(r-a)CO_2 with conventional monitoring and venous-to-arterial PCO_2 gap [P(v-a)CO_2] in patients with (Gr1) or without (Gr2) circulatory failure after cardiac surgery.

Materials and Methods: 14 patients undergoing elective cardiac surgery, with inserted arterial line and pulmonary artery catheter, were included in the study. Circulatory failure was defined as requirement for vasoactive support. Mean arterial pressure (MAP, mmHg), cardiac output (CO, l/min m²), blood lactate (L, mmol/l) and arterial blood gas were measured every two hours during a 12-hour post-operative period. PrCO_2 was monitored as well with the Tonocap™ *via* a nasogastric tonometer (Trip™ catheter) P(r-a)CO_2 and P(v-a)CO_2 (mmHg) were calculated. Data (mean ± SE) were analyzed using Wilcoxon and Mann-Withney tests.

Results: In response to increased O_2 requirements, CO increased significantly in Gr2 but did not change in Gr1. L tended to be higher in Gr1. P(r-a)CO_2 was larger in Gr1 at HO and was the sole parameter to be different between Gr1 and Gr2 at H0. Furthermore, it increased to a larger extent in Gr1 from H0 to H12. P(v-a)CO_2 did not vary significantly (Table).

$^{*}p < 0.05$ vs H0-Hx, $^{\#}p < 0.05$ Gr1 vs Gr2

Conclusion: Increased P(r-a)CO_2, after cardiac surgery, is rapidly associated with requirements for vasoactive therapy. Since P(v-a)CO_2 did not change, increased P(r-a)CO_2 suggests a selective hypercarbia in gastrointestinal tract consecutive to diverted blood flow to vital organs This marker may be an early indicator of gastrointestinal hypoperfusion and could help to optimize treatment in circulatory failure

A.182 Systemic and regional tissue perfusion in response to increasing metabolic demands after cardiac surgery

S M. Jakob, E. Ruokonen, J. Takala *University Hospital Kuopio, Finland*

Objective: To assess the adequacy of systemic, regional and local splanchnic perfusion after cardiac surgery

Materials and Methods: 17 patients after coronary bypass (CABG) surgery were studied Systemic (PA catheter) and regional (dye dilution) hemodynamics and O_2-transport and gastric mucosal pCO_2 (tonometry) were measured every three hours from arrival to the ICU until extubation

Results and Discussion: Systemic VO_2 increased from 126 ± 20 to 136 ± 16 ml/min m² ($p = 0.028$) Lactate/pyruvate ratios (L/P) were initially high in all vascular beds. Splanchnic O_2-extraction was high and increased despite stable systemic and decreasing femoral O_2-extraction Splanchnic L/P decreased but the hepatic vein-arterial pCO_2 gap increased.

	Baseline	3 h	6 h	p
Flows (l/min m²)				
– systemic	2 9 ± 0 7	3 1 ± 0 6	3 2 ± 0 6	
– splanchnic	0 7 ± 0 2	0 7 ± 0 2	0 6 ± 0 1	
– femoral	0 2 ± 0 1	0 2 ± 0 1	0 2 ± 0 1	
O2 extraction (%)				
– systemic	0 3 ± 0 1	0 3 ± 0 1	0 3 ± 0 1	
- splanchnic	0 4 ± 0 2	0.5 ± 0 1	0 5 ± 0 1	0 018

pCO2 gaps (kPa)				
– hepatic v – a	0 5 ± 0 2	0 5 ± 0 1	0 6 ± 0.2	0 019
– femoral v – a	1 1 ± 0 3	1 0 ± 0 3	1 0 ± 0 3	
– mucosal – a	0 5 ± 1 1	0 6 ± 0 7	0 6 ± 0 6	
L/P				
– arterial	14 ± 2 3	14 ± 2 8	12 ± 1 0	<0 001
– hepatic	18 ± 15	11 ± 3 3	11 ± 4 0	0 047
– femoral	17 ± 2 4	16 ± 2 7	15 ± 2 5	

Statistics MANOVA for repeated measurements

Conclusions: Metabolic demands increase after CABG. Regional L/P and pCO2 gaps indicated marginal tissue perfusion. Splanchnic tissue perfusion remains at risk early after CABG despite stable systemic hemodynamics

A.183 Can pharmacological intervention re-establish splanchnic blood flow during carbon dioxide-pneumoperitoneum? An experimental model

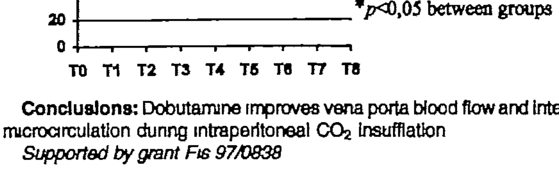
M. Agustí, J I. Elizalde, R. Adàlia, P Taurà, A Cifuentes, C Gomar
Hospital Clínic, Barcelona University, Barcelona, Spain

Background: Elevated intraabdominal pressure (IAP) due to gas insufflation may result in splachnic blood flow impairment.

Goal of Study: To investigate the role of beta-adrenergic drugs on splanchnic blood flow and intestinal mucosa microcirculation during CO_2-pneumoperitoneum.

Materials and Methods: 18 pigs, weighting 25–30 kg, were anesthetized and mechanically ventilated. Peritoneal cavity was insufflated with CO_2 at 15 mmHg during 1 hr. Then, the animals were randomized in two groups of 9 pigs each one. Dopamine (AG) and dobutamine (BG) at 5 µg/kg/min, respectively, were infused during 30 min. The follow variables were analyzed hemodynamic parameters, hepatic artery blood flow (HBF), superior mesenteric artery blood flow (SMABF) and vena porta blood flow (VPBF) with perivascular flowmeter, and intestinal microcirculation with laser-Doppler flowmetry These variables were recorded at baseline (T0), at 15, 30, 45 and 60 min (T1, T2, T3, T4), at 15 and 30 min after started vasoactive drug infusion (T5, T6) and at 15 and 30 min after stopped infusion (T7, T8). Statistical analysis with paired t test were performed

Results: HBF, SMABF, VPBF and intestinal microcirculation decreased with gas insufflation in all times respect to baseline ($p < 0.05$). Any vasoactive drug used modified HBF and SMABF. Only Dobutamine increased VPBF ($p < 0.05$). The changes of intestinal microcirculation are shown in figure.



Conclusions: Dobutamine improves vena porta blood flow and intestinal microcirculation during intraperitoneal CO_2 insufflation

Supported by grant Fis 97/0838

A.184 Impact of ventilation with positive end-expiratory pressure on splanchnic oxygenation

A Fournell, L A. Schwarte, T W.L. Scheeren *Department of Anaesthesiology, Heinrich-Heine-University, Duesseldorf, D-40255 Duesseldorf, Germany*

Background and Goal of Study: To evaluate if normalization of cardiac output (CO) reverses the attenuation of local intracapillary haemoglobin saturation (HbO_2) of gastric mucosa by PEEP (Positive End-Expiratory Pressure) during IPPV (Intermittent Positive Pressure Ventilation).

Materials and Methods: Four healthy, anaesthetized dogs were repeatedly studied (7 experiments) The animals were chronically instrumentated with carotid loops and an ultrasonic flowprobe implanted around the pulmonary artery to allow the continuous measurement of systemic mean arterial pressure (MAP) and CO We continuously measured HbO_2 of gastric mucosa (EMPHO II, Erlanger Microlightguide Spectrophotometer)[1] and total body oxygen consumption (VO_2, Datex Deltatrac™, Datex Instrumentation Corp., Helsinki, Finland) Arterio-venous oxygen content difference ($C_{(a-v)}O_2$) could be derived from CO and $\dot{V}O_2$ After obtaining baseline values during IPPV and ZEEP (Zero End-Expiratory Pressure) PEEP (15 cmH_2O) was added To compensate the reduction of CO due to PEEP, HES (hydroxyethyl starch 6%) was infused until CO reached baseline values during ZEEP

Results and Discussion: Despite of unimpaired systemic oxygen saturation, PEEP reduced HbO_2 of gastric mucosa from 55.1 ± 4 2% to 42.1 ± 4.7% (mean ± SEM). CO dropped from 67 7 ± 4 9 ml min^{-1} kg^{-1} to 33.9 ± 4 6 ml min^{-1} kg^{-1} and MAP from 66 4 ± 1 1 mmHg to 51.3 ± 2 4 mmHg. $C_{(a-v)}O_2$ increased simultaneously from 6.4 ± 0 2 ml 100 ml^{-1} to 10.8 ± 2.0 ml 100 ml^{-1}. Whereas infusion of HES during PEEP ventilation not only normalized CO to baseline values, but MAP and $C_{(a-v)}O_2$ as well, HbO_2 reached only 48.1 ± 3.3%, a statistically significant improvement compared to HbO_2 during ventilation with PEEP before HES infusion ($p < 0.05$, Wilcoxon signed rank test), but still below baseline values ($p < 0\ 05$).

Conclusions: Our findings demonstrate that the side effects of PEEP on systemic circulation can be fully compensated by restoring preload But normalizing systemic flow and pressure did not completely normalize HbO_2 of gastric mucosa. This further emphasizes that global measurements of variables of systemic circulation and oxygenation do not necessarily reflect regional abnormalities of tissue oxygenation. Therefore, in view of the utmost importance of dysoxia especially in the splanchnic region in the pathogenesis of multiple organ dysfunction syndrome, monitoring of HbO_2 of intestinal mucosa during ventilation with PEEP may be particularly useful in the care of the critically ill patient

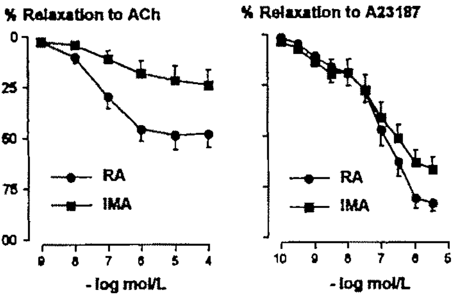
A.185 Comparison of endothelial function in the internal mammary artery and the radial artery

C. Huraux[1], K. Yamagushi[2], F Szlam[2], J.H. Levy[2] [1]*Department of Anesthesiology, Hôpital Pitié-Salpêtrière, Paris, France,* [2]*Department of Anesthesiology, Emory, Atlanta, USA*

Background and Goal of Study: We have previously found that internal mammary arteries (IMA) exhibit substantial variability of endothelium-dependent vascular relaxation. Recently, the use of radial artery (RA) grafts for CABG has been reintroduced The long-term patency of these grafts may depend on the ability of these vessels to produce nitric oxide (NO), which has anti-atherosclerotic properties We therefore sought to determine if RA might exhibit a more preserved endothelial function as compared to the IMA.

Material and Methods: In vitro isometric tension studies were performed on RA (n = 5) and IMA (n = 67) segments from patients undergoing CABG. Vessels were preconstricted with the thromboxane analogue U466 19 (10 nM) and exposed to increasing concentrations of either acetylcholine (ACh), calcium ionophore A23187, or nitroglycerin.

Results & Discussion: Both RA and IMA relaxed 100% of the preconstricted tension to nitroglycerin. As shown in figure 1, endothelium-dependent vascular relaxations to ACh and A23187 were substantially greater in the RA (50 ± 7 and 88 ± 5% respectively) as compared to the IMA (23 ± 7 and 69 ± 5%, respectively, $p < 0.05$ vs RA for both). The RA was also more reactive to vasoconstrictors than the IMA, including (all maximum responses in grams) KCl (10 ± 1 vs 2 ± 0), and thromboxane analogue (14 ± 1 vs 4 ± 1).



Conclusion: RA is much more vasoactive than the IMA. The enhanced endothelium-dependent vascular relaxation may have implications for the long term patency of RA grafts as endothelium-derived nitric oxide inhibits intimal proliferation and atherosclerosis. The increase in vasoconstrictor responses of the RA may predispose these vessels to spasm and suggests that the use of vasodilator therapy after RA graft placement may be beneficial

A.186 Pressure-flow relationship of arterial and venous bypass grafts: influence of volume changes and pharmacological vasodilatation

B.H. Walpoth, P Neidhart, A. Bosshard, B Kipfer, O.M. Hess, U. Althaus, T. Carrel. *Thoracic & Cardiovascular Surgery, Anaesthesia, Cardiology, University Hospital, Berne, Switzerland*

Purpose: To evaluate the influence of perfusion pressure and volume changes on intraoperative coronary blood flow and coronary flow reserve of arterial and venous bypass grafts.

Methods: Coronary blood flow was measured in 20 consecutive patients undergoing myocardial revascularisation for coronary artery disease. Flow measurements (transit time; CardioMed, Medi-Stim, Norway) were performed after discontinuation of cardiopulmonary bypass (CPB) in the IMA graft to LAD and in saphenous vein grafts at different aortic pressures induced by CPB volume changes [1]. Coronary flow reserve (CFR) was measured during maximal vasodilation at increasing doses of adenosine (2, 11, 23 μg/kg/min) Aortic pressure was kept constant by controlled CPB volume infusion during adenosine administration

Results: (1) Resting flow in the IMA graft was 33 ± 13 ml/min and coronary resistance 2.8 ± 1.9 Ω Flow in the vein graft was 68 ± 31 ml/min and resistance 1.4 ± 0.7 Ω (MAP = 75 ± 7 mmHg).

(2) A linear pressure-flow relationship was found for arterial ($r = 0.59$, $p < 0.02$ at maximal adenosine dosis) and venous ($r = 0.56$, $p < 0.06$) bypass grafts

(3) Coronary flow reserve was 1.7 for the IMA and 1.6 for the vein grafts. In the 20 patients a normal CFR (>2 0) was observed in 5 ima and in 6 venous coronary grafts

(4) Adenosine showed a dose-dependent effect on CFR: 2 μ/kg/min IMA 1.1, SVG 1 0; 11 μ/kg/min: IMA 1 3, SVG 1.4; 23 μg/kg/min. IMA 1.4, SVG 1 5; 23 μ/kg/min with infusion of volume· IMA 1 7, SVG 1 6.

Conclusions: Intraoperative flow measurement can be accurately obtained by the transit time technique. A normal coronary flow reserve was observed only in 30% of all patients due to relatively high resting flow (graft and native vessel). A linear pressure-flow relationship was found for arterial and venous grafts at maximal pharmacologic vasodilation

A.187 Haemodynamic effects, myocardial ischaemia, and timing of extubation with TIVA propofol-sufentanil *vs* midazolam-sufentanil-isoflurane anaesthesia for CABG surgery

K. Jovanovic, P. Romic, N. Filipovic, M. Surbatovic *Clinic of anesthesiology and intensive therapy, Military Medical Academy, Belgrade, Yugoslavia*

Background: Fundamental principles of anesthesia for coronary artery bypass graft (CABG) surgery include maintaining hemodynamic stability and minimizing myocardial ischemia. To provide anesthesia, an opioid is usually delivered in combination with a hypnotic drug or potent inhalational anesthetic The effects of TIVA (total intravenous anesthesia) propofol-sufentanil anesthesia versus midazolam-sufentanil-isoflurane anesthesia were evaluated and compared.

Methods: We randomized 44 patients, ASA grade 2 or 3, undergoing CABG surgery to receive either propofol-sufentanil anesthesia (propofol 5 mg/kg/h prior to sternotomy, 3 mg/kg/h thereafter [n = 24] and sufentanil 0 2 μg/kg for induction, 0 2–0 6 μg/kg/h for maintenance, total doses 5 μg/kg), or midazolam (30 μg/kg/h from induction to skin closure), sufentanil (max total doses 7 μg/kg) and isoflurane 0.5–2 vol% Hemodynamic (mBP, HR, CPV, PCWP, CI, SVRI, PVRI) and ECG were determined in seven time periods. II, aVL and V_5 ST-segment analysis was used for the detection of myocardial ischemia.

Results: The measured cardiovascular parameters were satisfactory and usually similar for both groups. The percentage of patients with intraoperative ST-segment deviation (15 ± 3% vs. 14 ± 4%) did not differ significantly between the two groups. The incidence of intraoperative hypotension (62% vs. 51%, $p = 0\ 01$), the use of inotropic/vasopressor medications (70% vs. 60%) were significantly greater in the propofol-sufentanil group The incidence of hypertension (43% vs 52%, $p < 0.01$) and the use of antihypertensive medications were significantly less in the propofol-sufentanil group The midazolam-sufentanil-isoflurane group received greater total doses of sufentanil (7 μg/kg vs 5 μg/kg, N.S.). Patients receiving propofol were extubated earlier, median 10 1 h vs. 12.1 h; $p = 0.005$.

Conclusions: The study suggest that most patients undergoing CABG surgery can be safely anesthetized with TIVA propofol-sufentanil without increased intraoperative myocardial ischemia, increased hypotension or hypertension, compared to an midazolam-sufentanil-isoflurane technique requiring greater dosing of sufentanil.

A.188 Effects of remifentanil and fentanyl on perioperative oxygen consumption in patients undergoing myocardial revascularization

C. Reavley, A. Reidel, S. von Kier, D Royston. *Anaesthetic Department, Harefield Hospital, Harefield, Middlesex UB9 6JH, UK*

Background and Goal of Study: Remifentanil has been shown to obtund major stress events during cardiac anaesthesia when used in combination with propofol. The purpose of this study was to measure the oxygen consumption (VO_2) of patients receiving remifentanil during CABG surgery and to compare it with that of patients receiving fentanyl

Materials and Methods: Using a randomised, double blind, comparative design, 12 patients with ejection fractions >0 35 undergoing elective CABG surgery were randomised to receive either remifentanil (group R: n = 6) or fentanyl (group F· n = 6) analgesia Following induction with propofol (0 5 mg/kg) and relaxation with pancuronium (0.15 mg/kg), anaesthesia was maintained with a propofol infusion (3 mg/kg/hr). Group R received an infusion of remifentanil (rate 1 μg/kg/min) with simultaneous boluses of placebo equivalent in volume to the fentanyl given in group F Group F received an induction bolus of fentanyl (15 μg/kg) followed by further maintenance boluses (2 μg/kg) with a simultaneous infusion of placebo equivalent in volume to the remifentanil given in group R. The protocol required that the rate of infusion of remifentanil and the number of boluses of fentanyl were adjusted to maintain control of cardiovascular indices within tight limits both on and off cardiopulmonary bypass Hypothermic (T = 28°C), non-pulsatile perfusion with crystalloid cardioplegia were used VO_2 was measured using the Datex Deltatrac CI, MPAP and SvO_2 were measured using an Oximetrics multilumen pulmonary artery flotation catheter. VO_2, CI, SvO_2, MPAP, IABP, MAP and HR were recorded after induction of anaesthesia (T1), after sternal incision (T2), immediately prior to giving protamine post bypass (T3) and immediately prior to transfer to the ICU (T4).

Results and Discussion: The two groups were matched for age, weight, length of surgery and bypass variables. Mean VO_2 was unchanged at T1 and T2 and equal in both groups Between T2 and T3 mean VO_2 rose from 90.2 to 122 2 ml/min/m^2 ($p < 0.01$) in group F but remained close to baseline levels in group R (T2 88 2, T3 92 2 ml/min/m^2). Mean VO_2 was significantly higher in group F than in group R at T3 (F 122 2 ml/min/m^2 R 90.2 ml/min/m^2 [$p < 0.01$]) Between T2 and T3 mean CI rose significantly in both groups (R· 2.0 to 2 7l/min/m^2 F 2.0 to 2 9l/min [$p < 0.01$]). Mean SvO_2 fell in group F (from 80.3 to 74.3%; $p = 0.04$) but remained unchanged in group R. There were no significant differences in mean HR, MAP or MPAP between the two groups at T3 Despite a similar rise in cardiac index in both groups, oxygen consumption remained close to baseline levels in the remifentanil group

Conclusion: The low oxygen consumption seen with remifentanil may have important implications for patients who have a reduced oxygen supply associated with either impaired gas exchange or poor myocardial function.

A.189 Myocardial protection during coronary artery bypass graft surgery with thoracic epidural analgesia

F.M. Lyons, B.J. Riedel, M. Haw[1], D. Royston. [1]*Department of Anesthesiology and Cardiothoracic Surgery, Harefield Hospital, Middlesex, UK*

Background and Goal of Study: TEA encourages a favourable pattern of coronary artery blood flow via selective vasodilation of stenotic atherosclerotic segments [1], increased subendocardial perfusion [2] and, as shown in animal models, a subsequent reduction in infarct size [2, 3]. Attenuation of the stress response, with reduced post cardiopulmonary bypass (CPB) catecholamine levels (CA's), may reduce coronary vasoconstriction distal to stenoses – shown to have an upregulated α-receptor profile. Our aim was to determine whether the proposed beneficial effects of TEA could reduce perioperative ischaemic injury with improved cardiac outcome.

Methods: Following ethical approval, 20 CABG patients (NYHA II or III, LVEF > 50%) were randomised to general anaesthetic (GA) (n = 10) using fentanyl (10–15 mcg/kg), propofol and isoflurane or a TEA (n = 10) (C7-T1 – 0.1 ml/kg 0.5% bolus + 0.1% infusion bupivicaine + 2 mcg/ml fentanyl for 72 hours following surgery) combined with intra operative intravenous propofol infusion. Two channel holter monitoring for ST segment elevation (>2 mm) and depression (<1 mm), pulmonary artery catheter derived haemodynamics, troponin-I (cTn-I), creatine kinase (CK and CK-MB) and CA's were measured at defined time points over 72 hours. Pre and post operative ECGs were recorded up to 6w following surgery

Results: Haemodynamic parameters, CK-MB, preoperative ST segment changes and postoperative ST segment depression revealed no differences between groups Postoperatively there was a significant **reduction** in both the degree ($p < 0.04$) and duration ($p < 0.005$) of ST segment elevation, CA's (noradrenaline; $p < 0\ 05$ @ 1, 12, 24 h post CPB), cTn-I ($p < 0.05$ @ 6 h post CPB; 3 5 ± 0 6 vs. 12.4 ± 4.2 ng/ml;), total CK ($p < 0\ 05$ @ 1, 3, 6, and 72 h post CPB) in the TEA group One new perioperative myocardial infarction was suffered in the GA group.

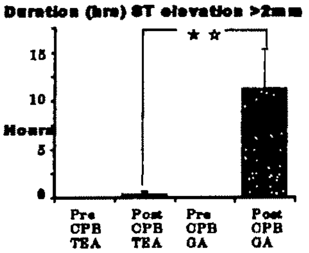

Figure 1 Duration (hours) of ST segment elevation (<2 mm) following CPB; mean ± sem for 72 h post CPB, ** = $p < 0\ 005$ [Mann-Whitney-U test]

Conclusions: The TEA group demonstrated a significant reduction in post CPB coronary vasoconstriction, as measured by surrogate markers of ischemia (cTn-I, ST segment elevation), which may relate to the direct vasodilatory effects of TEA, or a reduction in CA's The contributions to coronary vasoconstriction by endothelial dysfunction (associated with atherosclerosis and ischemia-reperfusion injury) were not explored Whether TEA may potentially confer a better postoperative cardiac outcome following CABG demands further study in a larger population

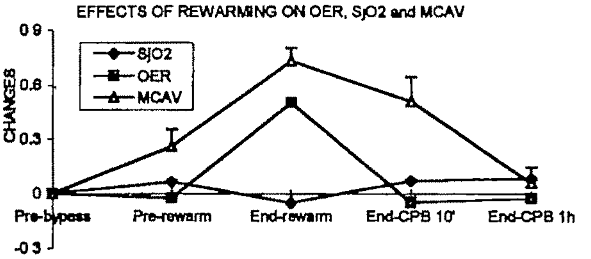
A.190 Effects of hypothermic rewarming phase during cardiopulmonary bypass on cerebral perfusion and cerebral oxygenation

F. Gao-Smith[1], D.N.F. Harris[2], S. Sapsed-Byrne[2]. [1]*Heartlands Hospital, Birmingham;* [2]*Hammersmith Hospital, London, UK*

Background & Goal of Study: It is known that hypothermia itself minimises cerebral damage However, rewarming may be harmful. We therefore investigated the effect of hypothermic versus normothermic bypass on cerebral perfusion and oxygenation.

Material & Methods: 16 patients undergoing elective coronary bypass were randomised into hypothermic (28°C n = 9) and normothermic (37°C n = 7) groups. Transcranial Doppler measurements of Middle Cerebral Artery Velocities (MCAV) were used to estimate cerebral perfusion. Blood gas measurements of simultaneous arterial and jugular bulb samples were used to evaluate cerebral oxygenation Samples were taken before bypass, before rewarming and at end-rewarm for the hypothermic group, and before bypass and after 30 and 60 minutes of bypass for the normothermic group. MCAV and samples were taken 10 minutes and then 1 hour after bypass Oxygen Exaction Ratio (OER) was calculated using a standard equation. All values were normalised to 100% of pre-bypass values as a baseline to indicate the differences between two bypass techniques The data were analysed using the Mann-Whitney U test.

Results & Discussion: There was a significant increase in MCAV and OER, but a significant fall in jugular bulb oxygen saturation (SjO_2) at end-rewarm (Fig. 1). The increase in cerebral perfusion and oxygen extraction may protect the brain against ischaemia during rewarming.



Conclusions: MCAV & OER were increased and SjO_2 fell during hypothermic rewarming phase.

A.191 Effects of hypothermic rewarming phase during cardiopulmonary bypass on NSE and S-100 release and cerebral lactate production

F. Gao Smith[1], D N.F. Harris[2], S Sapsed-Byrne[2]. [1]*Heartlands Hospital, Birmingham;* [2]*Hammersmith Hospital, London, UK*

Background & Goal of Study: It is known that hypothermia itself minimises cerebral damage. However, rewarming may be harmful Neurone-Specific Enolase (NSE) and S-100 are showing promise as specific markers of neuronal and glial cell damage following cardiac surgery[1] Cerebral hypoxia leads to the release of lactate from the brain[2]. The aim of this study was to explore the effect of hypothermic versus normothermic bypass on cerebral release of NSE, S-100 and lactate

Material & Methods: 16 patients undergoing elective coronary bypass were randomised into hypothermic (28°C n = 9) and normothermic (37°C n = 7) groups. Simultaneous arterial and jugular bulb blood samples were taken, before bypass, before rewarming and at end-rewarm for the hypothermic group, and before bypass, after 30 and 60 minutes of bypass for the normothermic group Samples were also taken 10 minutes and then 1 hour after bypass. Serum NSE & S-100 levels were measured using radioimmunoassay, and serum lactate using an enzymatic technique. Cerebral lactate production was expressed as the difference between jugular bulb and arterial levels. All values (apart from temperatures) were normalised to 100% of pre-bypass values as a baseline to indicate the differences between two bypass techniques. The data were analysed using the Mann-Whitney U test

Results & Discussion: There was no difference between the two groups with regard to age, gender, duration of bypass and clamping time There were no significant differences in NSE & S-100 levels and cerebral lactate production between the two groups.

Conclusions: Effect of rewarming on cerebral release of NSE, S-100 and lactate did not differ from that of normothermic bypass.

A.192 Effect of dexamethasone on extravascular fluid content after cardiopulmonary bypass

S Giannaris, M. Scholz[1], G. Wietasch[1], A. Hoeft[1], B. Schorn[2]. *Dept of Cardiovascular Surgery, Freiburg;* [1]*Dept. of Anaesthesiology and Intensive Care Medicine, Bonn;* [2]*Dept. of Thoracic and Cardiovascular Surgery, Göttingen, Germany*

Introduction: Cardiopulmonary bypass (CPB) causes a systemic inflammatory response with increased capillary permeability and accumulation of interstitial fluid. Specially, whole body oedema resulting from redistribution of body water between intra- and extravascular space or external fluid overload can lead to impaired organ function and postoperative morbidity[1]. This study was undertaken to determine the amount of oedema and to investigate if dexamethasone prevents fluid extravasation by suppression of inflammatory response[1].

Method: After ethical committee approval and written informed consent, twenty patients undergoing elective coronary bypass surgery were included in a randomised double-blind trial. Induction of anaesthesia was performed with 2 $\mu g \cdot kg^{-1}$ sufentanil and 0 1 $mg \cdot kg^{-1}$ pancuronium. Subsequently ten patients received placebo (plc) and the other ten 1 mg kg^{-1} body weight dexamethasone (dxm) Total blood volume (*TBV*) was estimated from hepatic elimination rate of indocyanine green[2] The amount of changes in extravascular body water ($\Delta EVBW$) was calculated from the difference between changes in total plasma volume and the corresponding net fluid balances. Measurements were carried out after induction of anaesthesia (A) and one (1 h), six (6 h), and twenty (20 h) hours after surgery. Statistical analysis was performed by 2-way ANOVA (repeated measures design).

Results: In the following table the changes of volume parameters are given as mean ± standard deviation

ΔTBV	A	1 h post OP		6 h post OP		20 h post OP	
[ml/kg] plc	0	−12 69	19 73*	−18 18	16 72**	−16 85	24 45**
dxm	0	−12 57	17 47*	−12 64	16 54*	−15 00	17 69**

* (**) $p < 0$ 05 (0 01) 1 h, 6 h, 20 h vs A

ΔEVBW							
[ml/kg] plc	0	58 80	13 55$	69 67	27 85$	55 57	25 46$
dxm	0	43 44	15 33$,#	48 94	18 26$,##	44 26	23 62$

$ $p < 0$ 001 1 h, 6 h, 20 h vs A, # (##) $p < 0$ 01 (0 001)· plo vs dxm

TBV decreased significantly after surgery in both groups Despite identical net fluid balances, in plc-group postoperative formation of tissue oedema exceeded that in dxm-group significantly

Discussion: This study demonstrates that whole body oedema formation can significantly be suppressed by pretreatment with corticosteroids Dexamethasone reduced accumulation of interstitial fluid obviously by inhibition of mediator triggered capillary leakage, which seems to be the main pathogenetic factor[1] of the inflammatory response to CPB

A.193 Pulmonary endothelial cytoprotection by fructose-1,6-diphosphate in cardiac surgery

B Riedel, A W. Fox[1], D. Royston. *Department of Anesthesiology, Harefield Hospital, UK, [1]Cypros Pharmaceutical Corporation, Carlsbad, CA, USA*

Background and Goal of Study: Cardiopulmonary bypass (CPB) may produce an **ischemia-reperfusion (IR) injury** to the pulmonary [1], coronary, and other vascular endothelium resulting in endothelial activation and expression of proinflammatory factors e g leukocyte adhesion molecules, procoagulant and vasoconstrictive factors Pulmonary vasoconstriction [2], increased RV-afterload and impaired RV-performance may follow **Fructose-1,6-diphosphate** (FDP), an intermediary glycolytic pathway moiety has cytoprotective effects through enhanced anaerobic ATP production, oxygen burst inhibition, modulation of leukocyte-endothelial cell interaction and preservation of endothelial barrier integrity [3]. We investigated whether FDP reduced CPB-associated ischemic changes, providing cytoprotection to the pulmonary endothelium and thereby prevent postoperative pulmonary vasoconstriction, as measured by pulmonary vascular resistance (PVRI).

Materials and Methods: 30 consenting, elective, CABG patients (LVEF > 45%) were randomised to FDP (250 mg/kg ivi) or 5% Dextrose (placebo) treatment prior to CPB in this ethically approved, double blind clinical trial

Results and Discussion: Both groups were similar with respect to age, CPB and aortic cross-clamp duration

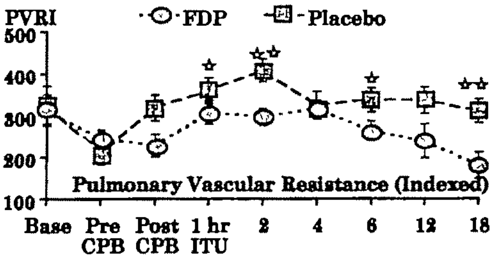

Figure PVRI, mean ± SEM, * = t [0 05, 29], ** = t [0 01, 29]

FDP attenuated mean PVRI (figure) increase for all patients and for subgroups with CPB < 90 or > 90 minutes, i e. 96 & 109 (FDP) vs. 112 & 141 (placebo) % of baseline values, respectively ($p = 0.017$, AUC; chi square analysis).

Conclusions: This data suggests that (i) the severity of postoperative pulmonary vasoconstriction relates to CPB duration and (ii) that FDP beneficially reduces PVRI and subsequent RV-afterload in the early postoperative period

A.194 Propofol inhibits myocardial lipid peroxidation during coronary artery bypass grafting surgery

M. Murat Sayin, Oya Ozatamer, R Taşoz, K Kılınç, T Neyyir Eren
Ankara University, Faculty of Medicine, Department of Anaesthesiology and Intensive Care, Turkey

Goal of the Study: To determine if propofol, when used for anaesthesia maintenance, acts as a free radical scavenger during coronary bypass grafting (CABG) surgery

Materials and Methods: Twenty-four patients assigned for CABG surgery having three major coronary artery occlusions and ejection fraction greater than 45% were selected for the study Patients in the control group (Fentanyl group, n = 14), after induction with fentanyl 10 mg/kg, midazolam 0.1 mg/kg, pancuronium 0.08 mg/kg, received fentanil infusion 10–30 mg/kg/hr, midazolam 0.1 mg/kg every 60 minutes, and pancuronium 0 04 mg/kg every 45 minutes for the maintenance of anaesthesia. Patients in the Propofol group (n = 10) after induction with the same drugs, received propofol infusion 3–6 mg/kg/hr, midazolam 0.1 mg/kg every 60 minutes, and pancuronium 0.04 mg/kg every 45 minutes for maintenance of anaesthesia during CABG surgery 0 2 g of atrial tissue biopsy is taken during cannulation for bypass, cross-clamp when the patient's rectal temperature was 29°C, after cross-clamp removal, and after decannulation Lipid peroxidation is assessed by the method of Mihara and Uchiyama in the atrial tissue samples.[1]

Results: The results of mean (± SD) lipid peroxidation levels during cannulation, cross-clamp, cross-clamp removal and decanulation in the fentanyl group were 45 6 ± 7.9, 63 6 ± 15 9, 74 5 ± 14.9, 72 8 ± 16 and in the propofol group were 34 4 ± 7 2, 38 9 ± 18 2, 43.9 ± 16 8, 43 8 ± 13 6 (nmols/gr wet tissue) respectively. In all sampling periods lipid peroxidation levels in the propofol group were lower than fentanyl group ($p < 0.05$) Although lipid peroxidation levels in the fentanyl group increased significantly ($p < 0$ 05) during CABG surgery, propofol group showed no increases ($p > 0$ 05).

Conclusion: Eventhough inhibition of lipid peroxidation by propofol is a known fact,[2,3] this was not shown in vivo during CABG surgery, in which reperfusion injury is a major problem We conclude that propofol is a potent inhibitor of lipid peroxidation during CABG surgery even in the lower maintenance doses.

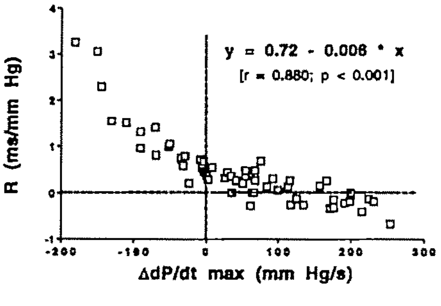
A.195 Is load dependence of rate of left ventricular relaxation coupled to contractile function in coronary surgery patients?

Stefan G De Hert *Dep Anesthesiology, Univ Hospital Antwerp, Belgium*

Background: Left ventricular (LV) relaxation rate is more dependent on systolic load in the failing heart than in the normal heart (1) It was suggested that this dependence might provide a clinical tool to evaluate individual cardiac function (2) The present study evaluated whether dependence of rate of LV relaxation on systolic pressures would allow estimation of individual LV contractile function in patients undergoing coronary surgery (CABG).

Methods: Patients (n = 80) with preoperative ejection fraction >40% were included LV pressures were measured with a tipmanometer inserted in the LV cavity. Paced heart rate was 90 beats/min. LV pressures were recorded during leg elevation, resulting in an increase of LV pressures The effects of leg elevation on myocardial function were evaluated by the changes in LV pressure and dP/dt_{max}. Effects of leg elevation on rate of LVP fall were evaluated by the changes in the time constant τ of isovolumic relaxation. Time constant τ was linearly fit to the corresponding end-systolic LVP and the slope R (ms/mm Hg) of this relation was calculated. R quantified changes in τ, induced by the increase of end-systolic LVP during leg elevation and described afterload dependence of LVP fall



Correlation between changes were calculated using Pearson's correlation coefficient

Results: Response of rate of LV relaxation to increase in systolic pressures with leg elevation was related to the contractile response. An increase in dP/dt_{max} with leg elevation was associated with a low value of R, while a decrease in dP/dt_{max} was associated with a high value of R ($r = 0.88$; $p < 0.001$) (Figure 1). The effects on R and dP/dt_{max} during leg elevation were also closely related to the changes in EDP ($r = 0.80$; $p < 0.001$ and $r = 0.84$; $p < 0.001$ respectively)

Conclusion: These data demonstrated that response of contraction and relaxation were coupled during leg elevation in patients undergoing CABG. The magnitude in changes of EDP with leg elevation was indicative for the response of parameters of contraction and relaxation.

A.196 Intrathoracic blood volume as a reliable cardiac preload indicator in mechanically ventilated PTS with PEEP

G Susini, A Tosoni, M. Tullii, G.F. Manfredi, R. Panzen, E. Villa, A. Attanasio. *Divisione di Anestesia e Rianimazione Istituto Europeo di Oncologia, Milano, Italy*

Increased intrathoracic pressure, during positive pressure ventilation, reduces cardiac output (CO) because of a decrease in venous return. In mechanically ventilated patients, neither central venous pressure (CVP) nor capillary wedge pressure (PCWP), reflect cardiac preload accurately (1).

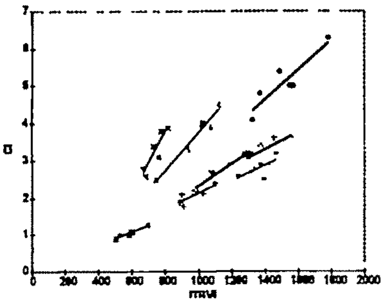
Goal of Study: to identify which of the two, CPV and intrathoracic blood volume (ITBV) better correlate to CO at different PEEP levels before and after an infusion of a determined volume of plasma expander

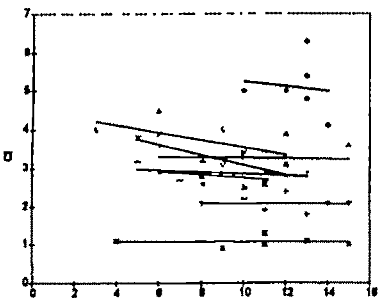
Material and Methods: in 8 surgical pts with stable hemodynamic conditions, CVP, ITBV index and cardiac index (CI) were measured at two different PEEP levels i.e. 10, 15 cmH_2O, before and after infusion of 500 ml of colloids. Measurement of ITBVI and CI were provided by the PiCCO system by means of a femoral arterial thermodilution catheter and an iced bolus with 15 ml of saline solution injected through a central venous line.

Results and Discussion: In our study, ITBVI and CVP were correlated to CI. The individual correlations coefficient (r) are illustrated in the following table:

Patient	1	2	3	4	5	6	7	8
CIvsITBVI	0 90	0 67	0.84	0.98	0 91	0 91	0.98	0 75
CIvsCVP	–0 71	–0 31	–0 03	–0 45	–0 19	–0 12	–0 20	–0 57

On average, correlation between CI and ITBVI was r = 0 70 (fig. a) and correlation between CI and CVP was r = –0.04 (fig. b).





To avoid CO decrease during mechanical ventilation (MV) is fundamental to assess actual cardiac preload. Both CVP and PCWP tend to increase during MV with PEEP in spite of a reduced venous return, thus they are not reliable preload indicators.

In our study the correlation between CI and CVP and between CI and ITBV were –0 04 and 0 70 respectively.

Conclusions: In mechanically ventilated pts with PEEP, ITBVI is a better cardiac preload indicator than CVP.

A.197 Haemodynamic effects of an agonist of the vasopressin system for treatment of refractory hypotension at anaesthetic induction in patients on chronic ACEI-therapy: preliminary results

D. Eyraud, S. Brabant, N. Dieudonné, M H. Fléron, M Bertrand, S Mouren, P. Coriat *Department of Anesthesiology, Pitié-Salpêtrière, Paris, France*

Background: to determine the circulatory effects of terlipressine, an agonist of the vasopressin system, when used to counteract intraoperative hypotension in patients chronically treated by ACEI, when hypotension was refractory to conventional therapy with agonists of the sympathetic system.

Patients: twenty two patients, chronically treated with ACEI's, undergoing a peripheral vascular surgery were prospectively studied. A radial artery catheter was inserted prior to induction of anaesthesia

Methods: after an intravenous infusion of 10 ml/kg of Ringer's Lactate, propofol 1.5 mg/kg, sufentanil 0 5 mcg/kg and atracurium 0.5 mg/kg were given for induction. A transoesophageal echocardiography probe was used to assess left ventricular function (LVF). When systolic arterial pressure (SAP) became lower than 85 mmHg, a bolus of 6 mg of ephedrine or 100 mcg of phenylephrine was administered. This bolus was repeated two folds if SAP did not remain above 100 mmHg during 1 minute If this goal was still not obtained, we injected a bolus of 1 mg of terlipressine intravenously and haemodynamic parameters were recorded each 30 seconds during 6 minutes.

Results: hypotension was refractory to conventional vasopressor therapy in 6 of 22 patients. One minute after the injection of terlipressine the SAP increased from 83 ± 2 mmHg to 103 ± 10 mmHg. Peak value of SAP reached 119 ± 15 mmHg. This was not associated with change in fractional area change (0.57 ± 0.07 vs 0.54 ± 0.08) and heart rate (55 ± 4 vs 52 ± 4). Wall stress significantly increased from 39 ± 8 to 65 ± 15 (10^3 $dynes.cm^{-2}$)

No additional injection of vasopressor was needed during the perioperative period. No change in ST-segment was observed after the injection. Posperative diuresis was adequate in all cases

Conclusion: a bolus of 1 mg of terlipressine is effective to counteract intraoperative hypotension in patients chronically treated with ACEI who present hypotension refractory to conventional therapy.

A.198 A prospective, randomized comparison of haemodynamic behaviour and treated haemodynamic side effects during remifentanil/propofol/oxygen, remifentanil/desflurane/oxygen, remifentanil/sevoflurane/oxygen and alfentanil/isoflurane/nitrous oxide anaesthesia for ENT surgery

T. Loop, H.-J. Priebe. *Department of Anaesthesia, University Hospital, 79106 Freiburg, Germany*

Background and Goal of Study: The pharmacokinetics of remifentanil (REM), desflurane (DES), and sevoflurane (SEV) make them highly attractive for ENT-surgery. Accordingly, this study was to evaluate the haemodynamic behaviour and treated haemodynamic side effects of REM/propofol (PRO), REM/DES, REM/SEV and alfentanil/isoflurane/N_2O/O_2 (control [CONTR]) anaesthesia.

Materials and Methods: Following approval by the local Ethics Committee, 120 patients were randomly assigned to either REM/PRO, REM/DES, REM/SEV or CONTR anaesthesia (n = 30 each). Blood pressure was determined non-invasively before anaesthesia, before and 1 and 5 min after intubation, before and 5 min after start of surgery, and at, and 1 and 5 min after extubation. Low mean arterial pressure (MAP, <60 mmHg) and heart rate (HR, $<50\ min^{-1}$) for >3 min were treated with either atropine or etilefrine Data were statistically analyzed by ANOVA (for repeated measures where indicated), and by χ^2 and Fisher's exact test (significance level $p < 0.05$).

Results and Discussion: Patient characteristics were comparable between groups. Following induction of anaesthesia, MAP and HR decreased most in the REM groups (Table 1). There was no haemodynamic response to intubation in these groups. More patients receiving REM/PRO and REM/SEV required treatment for hypotension and/or bradycardia when compared to the REM/DES and CONTR groups (Table 2).

Total	10 (33)	3 (10)*	12 (40)	3 (10)*

Haemodynamic alterations hypotension and/or bradycardia * $p < 0\ 05$ vs REM/PRO and REM/SEV

Conclusion: Baseline anaesthesia with REM effectively blocks the stimulus of laryngoscopy, intubation and surgery Discontinuation of REM does not result in a reactive hyperdynamic response

A.199 Veno (inf. *vena cava*) – arterial carbon dioxide difference during clamping for surgery of the abdominal aorta

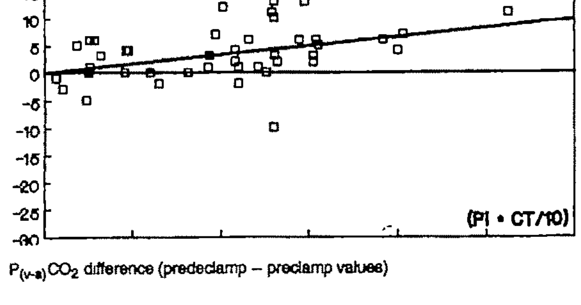
G Vretzakis[1], D. Papadimitriou[1], G Papadopoulos[2], M. Fatouros[2], V. Zervas[1], E Ferdi[1], G. Vassiliadou[1], E. Kapnni[1] [1] *Depts of Anes. & Vasc Surgery, "G Gennimatas" Hos. of Thessaloniki, [2] University of Ioannina, Greece*

Quantitative increase in veno-arterial ΔPCO_2 has been observed in tissue dysoxia related situations. However, in a controlled animal setting, regional veno-arterial ΔPCO_2 ($P_{(v-a)}CO_2$) was increased only with ischemic and not with hypoxic hypoxia. During aortic clamping in humans the degree of peripheral ischemia is reversery related to the extend of the collateral circulation This study was aiming to investigate the relation of distal $P_{(v-a)}CO_2$ with the duration of the aortic occlusion (CT) and with the ankle-brachial pressure index (PI).

Material & Methods: After institutional protocol approval, 42 male patients (age: 66.4 ± 8.2, ASA I–III, EF > 40%) referred for elective infrarenal aortic surgery were studied Under continuous epidural combined with general anesthesia, 30 patients (Doppler mean bilat. PI = 0 94 ± 0.24) had aneurysm repair (AAA) with prosthetic tube graft, while in the rest (Doppler mean bilat. PI = 0 36 ± 0 14) repair was aiming to their occlusive disease (OD) of the difurcation Preoperatively, a heparinized inf v cava sampling line (via femoral) was introduced. Blood was transfused after data collection Patients were breathing $FiO_2 = 0.45$ and no hypoxic state was recorded during the procedure

Results: Total aortic occlusion in AAA (proximal + distal anastomoses) was 57 4 ± 12 0 min and 28 2 ± 9 2 in OD (only proximal) During clamping, $P_{(v-a)}CO_2$ was increased mainly in AAA (Table) The differences between pre-declamp and preclamp values of $P_{(v-a)}CO_2$ were correlated with PI, CT and product (PI * CT). Best correlation was found with the latter (fig), while it was positive with both PI (r = 0 371) and CT (r = 0 324) Although $P_{inf\ v\ c}CO_2$ remained elevated in the early declamping period, $P_{(v-a)}CO_2$ was decreased because of the systemic hypercarbia.

Discussion: The findings of this study and observations in animals concerning lower body tissue ischemic dysoxia are similar. Although distal venous CO_2 is increased, low flow from this part leads to decreased CO_2 load to the lungs during clamping[2] Difference in collateral vessels (reflected in PI) modifies the distal venous CO_2 augmentation



$P_{(v-a)}CO_2$ difference (predeclamp – preclamp values)

	Preclam	Pre-declamp	15′ after
AAA	5 56 ± 3 6	8 86 ± 4 3*	5 31 ± 3 7
OD	7 0 ± 3 3	8 43 ± 4 6	7 2 ± 3 2

$P_{(v-a)}CO_2$ values in mmHg, mean ± SD, * denotes $p < 0\ 05$ (t-paired)

A.200 Cardiovascular and catecholamine responses to endovascular abdominal aortic aneurysm repair

J P. Thompson[1], J.R. Boyle[2], M.M. Thompson[2], P R.F Bell[2], G. Smith[1].
University Departments of [1]Anaesthesia, [2]Surgery, Leicester Royal Infirmary, Leicester, LE1 5WW, UK

Background: Endovascular repair of abdominal aortic aneurysms (AAA) has been proposed as a less invasive alternative to conventional surgery, although there are few data to confirm this. We have compared haemodynamic, catecholamine and acid-base changes in patients undergoing endovascular or conventional AAA repair

Methods: 24 patients for AAA repair were divided into two equal groups, both received similar anaesthetic regimes Cardiovascular variables including cardiac index (CI), systemic vascular resistance index (SVRI), blood gases, plasma adrenaline and noradrenaline were measured prior to surgery, before, and 5 minutes after aortic clamping and clamp release (conventional) or occlusion & release (endovascular) and analysed by ANOVA and paired t-tests.

Results: (Mean (SEM))

Conventional	Baseline	Pre-xc	Post-xc	Pre-xc release	Post-xc release

$^{*}p < 0\ 05$ compared with pre-xc, $^{\dagger}p < 0\ 05$ between groups

Discussion: There was a significant metabolic acidosis and increase in p_aCO_2 at aortic unclamping in the conventional group, but no parallel changes in the endovascular group. Changes in cardiac output were less than previously reported[1], which may be related to anaesthetic technique

Conclusion: Cardiovascular variables were stable in the endovascular group, and plasma adrenaline concentrations significantly lower compared to the conventional group

A.201 Effects of dobutamine on haemodynamic changes during surgical procedures performed in the genupectoral position. An echo-Doppler study

G Galimberti, G Berlot, R. Muchada, A. Gullo *Dept of Anaesthesia and Intensive Care, University of Trieste Cattinara Hospital, 34100 Trieste, Italy*

Background and Goal of Study: In the anaesthetized patients the genu-pectoral position has been associated with a marked decrease of the cardiac output and $etCO_2$ and a sharp increase of the systemic vascular resistences (1). This cardiovascular effect compromising tissue perfusion, can come to fearsome effects during the perioperative period (2) The use of low-invasive continuous haemodynamic monitoring offers information allowing an early diagnose and therapeutic intervention of cardiovascular alterations (1, 3). The study aim was to evaluate the cardiovascular effects of the genu-pectoral position during infusion of dobutamine.

Materials and Methods: Only patients in ASA1 class undergoing scheduled lumbar discal surgery were involved in the study, after informed signed consent, and were treated with the same anaesthetic protocol The dobutamine was given by continuous infusion at a rate of 3 μg/Kg/min, commencing 10 min before the induction of anaesthesia. Anaesthesia was induced with Fentanyl (1 μg/Kg), Propofol (1–2 mg/Kg) and Vecuronium bromide (0.12 mg/Kg) Anaesthesia was maintained with Isoflurane (<1 MAC) in N_2O-O_2 (50:50) and Fentanyl 1 μg/Kg/h After the induction, with the patients still lying in the supine position, an echodoppler probe (Dynemo 3000) was inserted via the nose into the oesophagus This device includes a 5 MHz pulsed doppler and a 10 MHz M-mode imaging system synchronized and able to measure simultaneously and continuously both blood flow velocity in the thoracic aorta and aortic diameter. Monitoring included the ECG, $etCO_2$, SpO_2, aortic blood flow (ABF), aortic stroke volume (SVa), aortic total systemic vascular resistences (TSVRa), mean arterial pressure (MAP), HR, aortic diameter, pre-ejection period index (PEPi), left ventricular ejection time index (LVETi) and the PEP/LVET ratio. Three sets of continuous measurements were then averaged (in supine, kneeling, and risupine position) Data recorded during the three periods were analyzed with the Anova test. A $p < 0.05$ was considered statistically significant

Results and Discussion: Twelve consecutive patients were enrolled into the study The cardiovascular changes by knee-chest position comparing to supine position are illustrated in table n 1.

Table 1 Haemodynamic variables * supine vs genupect

Parameter	Supine	Genupect	Risupine	P value
ABF	4.89 ± 0.6	3.09 ± 0.6	3.5 ± 0.5	0.01*
MAP	83 ± 18	86 ± 15	87 ± 8	n.s
HR	81 ± 9	79 ± 9	79 ± 7	n.s
SVa	49 ± 11	39 ± 7	44 ± 10	0.03*
TSVRa	1817 ± 258	2228 ± 389	2201 ± 244	0.002*
PEPi	150 ± 16	142 ± 6	139 ± 7	n.s
LVETi	413 ± 33	388 ± 62	404 ± 18	n.s
PEP/LVET	0.37 ± 0.07	0.36 ± 0.05	0.33 ± 0.02	n.s.
$etCO_2$ KPa	4.48 ± 0.2	4.32 ± 0.2	4.11 ± 0.3	n.s
Diameter	27.3 ± 2.8	27.4 ± 2.9	27.3 ± 2.9	n.s

There was a statistically significant decrease of the ABF and the SVa and increase of the TSVRa in the genu-pectoral position without reduction of myocardial contractility, as indicated by the stability of both the PEPi and the PEP/LVET. No changes were observed in regard to MAP, HR, $etCO_2$ and therefore tissue perfusion.

Conclusion: Transoesophageal echodoppler could detect reductions of the ABF not otherwise detectable. Dobutamine seems to have beneficial effects on the preservation of ABF and tissue perfusion

A.202 Is load dependence of left ventricular relaxation influenced by β-adrenergic tone in coronary surgery patients?

Stefan G De Hert. *Dep Anesthesiology, University Hospital Antwerp, Belgium*

Background: Left ventricular (LV) relaxation rate in the failing heart is more dependent on systolic load than in the normal heart (1) The present study evaluated whether this dependence of rate of relaxation on LV pressures could be altered by β-adrenergic medication in patients undergoing coronary surgery (CABG).

Methods: Two groups of 10 patients with preoperative ejection fraction >40% were included. LV pressures were measured with a tipmanometer inserted in the LV cavity. Paced heart rate was 90 beats/min. LV pressures were recorded during leg elevation, resulting in an increase of LV pressures. The effects of leg elevation on LV contraction were evaluated by the changes in dP/dt_{max} Effects on LV relaxation were evaluated by the changes in the time constant τ of isovolumic relaxation. τ was linearly fit to the corresponding end-systolic LVP and the slope R (ms/mm Hg) of this relation was calculated R quantified changes in τ, induced by the increase of end-systolic LVP during leg elevation and described afterload dependence of LVP fall. In group 1, leg elevation was performed at baseline (*B*) and after administration of esmolol (*E*) 1 mg/kg (β-blocking agent). In group 2, leg elevation was performed at baseline and during administration of dobutamine (*D*) 5 μg/kg/min (β-stimulation). Correlations were calculated using Pearson's correlation coefficient. Comparison of slope and intercept of regression lines was performed using Student t-test

Results: A close relationship was observed between changes in dP/dt_{max} and changes in R in all conditions In group 1, dP/dt_{max} increased less after *E* and R was higher (0.315 ± 0.132 ms/mmHg at *B* and 0.816 ± 0.153 ms/mm Hg after *E* ($p < 0.001$)) Slopes and intercepts were not different, indicating that the individual values shifted along the same relation (Fig. 1) In group 2, dP/dt_{max} increased more during *D* and R was 0.039 ± 0.052 ms/mm Hg at *B* and 0.455 ± 0.149 respectively during *D*. Slopes and intercepts were not different, indicating that the individual values also shifted along the same relation (Fig. 2)

Fig 1

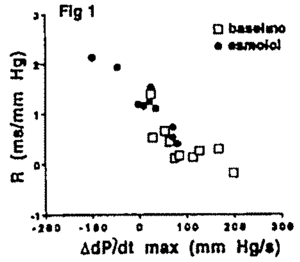

Fig 2

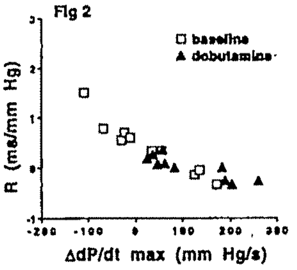

Conclusion: **E** increases, whereas **D** decreases load-dependency of LV relaxation. This change occurred along the same relationship, indicating that contraction and relaxation remained coupled

A.203 A second post-induction dose of propofol does not attenuate the haemodynamic responses to intubation

D Savva. *King Fahad Hospital, Riyadh, Saudi Arabia*

Background & Goal of Study: An EEG arousal reaction occurs during laryngoscopy and intubation which may be caused by a subcortical nociceptive input [1]. This can produce rises in heart rate and arterial pressure, resulting in myocardial ischaemia or infarction in susceptible patients. The aim of this study was to determine if a second bolus dose of propofol given immediately before laryngoscopy might attenuate these responses

Material & Methods: Twenty-six ASA 1&2 adult patients undergoing elective surgery requiring general anaesthesia and controlled ventilation were studied. Anaesthesia was induced with propofol 2 mg/kg and atracurium 0.6 mg/kg Patients were manually ventilated with isoflurane 0.8% and nitrous oxide 66% in oxygen. Two minutes after induction, patients received either propofol (Group P, n = 13) 1 mg/kg or intralipid 10% 0.1 ml/kg (Group C, n = 13).

Laryngoscopy and intubation was then performed. Heart rate (HR) and mean arterial pressure (MP) were recorded· (a) Before induction of anaesthesia (PR); (b) one minute after induction (PO), (c) one, three, five and ten minutes after intubation (1, 3, 5&10). Mean (SD) was calculated. Differences between groups (GR) were determined using unpaired 't' tests.

Results & Discussion: Both groups were comparable for age, weight and sex ratio HR and MP were similar in both groups before and after induction of anaesthesia. HR was significantly higher in the ten-minute period after intubation in Group P compared with Group C. There was no difference in MP between groups during this period.

GR	HR PR	HR PO	HR1	HR3	HR5	HR10
P	88 (21)	88 (17)	117** (12)	112** (10)	110** (12)	100** (13)
C	80 (19)	82 (13)	98 (12)	93 (12)	89 (12)	79 (13)
GR	MP PR	MP PO	MP1	MP3	MP5	MP10
P	90 (13)	81 (12)	98 (13)	83 (13)	80 (11)	73 (12)
C	98 (14)	83 (10)	102 (13)	88 (13)	84 (13)	77 (9)

Significant differences, * $p < 0.05$, ** $p < 0.01$

Conclusion: Surprisingly, the results show that a second post-intubation bolus dose of propofol 1 mg/kg produces an undesirable tachycardia following tracheal intubation.

A.204 Minimum dose of esmolol which attenuates the chronotropic response to intubation

D Savva *King Fahad Hospital, Riyadh, Saudi Arabia*

Background & Goal of Study: Rises in heart rate occur following laryngoscopy and tracheal intubation which may result in myocardial ischaemia or infarction in susceptible patients. Esmolol, a short-acting beta-adrenoceptor antagonist, has been shown to suppress these responses (1) The aim of this study was to determine the minimum dose of esmolol required for this purpose.

Material & Methods: Fifty-two ASA 1&2 adults undergoing elective surgery requiring general anaesthesia and controlled ventilation were studied Anaesthesia was induced with thiopentone 4 mg/kg and atracurium 0.6 mg/kg, and maintained with isoflurane 0.8% and nitrous oxide 66% in oxygen. Two minutes after induction, patients received either saline 10 ml (Group S, n = 11), esmolol 1 mg/kg (Group E1, n = 10), esmolol 2 mg/kg (Group E2, n = 10), esmolol 3 mg/kg (Group E3, n = 11), or esmolol 4 mg/kg (Group E4, n = 10). Two minutes later, laryngoscopy and intubation was performed Heart rate (HR) was recorded (a) Before induction of anaesthesia (PR), (b) one minute after induction (PO); (c) one, three, five and ten minutes after intubation (1, 3, 5&10) Mean (SD) was calculated Differences between Group S and other groups were determined using multiple unpaired 't' tests

Results & Discussion: All groups (GR) were comparable for age, weight and sex ratio. The HR was similar in all groups before and after induction of anaesthesia The HR was significantly lower for one minute after intubation in Group E1, for ten minutes in Group E3, and for three minutes in Group E4 than the HR in Group S.

GR	HR PR	HR PO	HR1	HR3	HR5	HR10
S	82 (20)	89 (19)	102 (15)	98 (15)	87 (17)	82 (17)
E1	77 (13)	82 (14)	89* (13)	85 (11)	80 (12)	77 (10)
E2	86 (15)	91 (9)	98 (11)	94 (11)	90 (11)	85 (8)
E3	79 (14)	87 (16)	82** (10)	76** (11)	72* (12)	69* (13)
E4	81 (14)	95 (7)	89* (8)	84* (12)	80 (11)	82 (10)

Significant differences, * p < 0 05, ** p < 0 01

Conclusion: A minimum of 1 mg/kg of esmolol is required to attenuate the chronotropic response to intubation.

A.205 Effects of halothane, isoflurane anaesthesia and magnesium infusion on heart rate variability

T.S Çeliker, C. Çeliker[1], S Küçukay, K Pembeci, M Tuğrul, F. Korkut[1]
Department of Anaesthesiology; [1]Cardiovascular Research Center, Istanbul Medical Faculty, Istanbul, Turkey

Background and Goal of Study: Heart rate variability (HRV) became a quantitative method showing the activity of autonomic nerve system High frequency (HF) is thought to be controlled by parasympathetic nervous system while low frequency (LF) by the interaction of sympathetic and parasympathetic nervous systems, and the LF/HF ratio to be a marker of sympathovagal balance (1). HRV reducing effect of different anaesthetics has been investigated (2). Magnesium (Mg) is known to have a positive effect on autonomic nervous system instability (3) We investigated the effects of halothane, isoflurane anaesthesia and Mg infusion on HRV.

Materials and Methods: Forty-one patients (pts) (23 male, ASA physical status I–II) 25–45 years of age, undergoing general anaesthesia for elective orthopedic surgery were included in this study The pts with the diseases and receiving medication that had an effect on HRV were excluded The pts were evaluated in four groups: In group I (no 12) anaesthesia induction was performed by halothane, in group II (no·11) Mg was being infused during halothane anaesthesia, in group III (no 10) isoflurane anaesthesia was given and in group IV (no:8) pts received Mg during isoflurane anaesthesia. Power spectral analysis was done with high definition program using fast Fourier transformation in LF and HF bands. The LF/HF ratios were calculated by dividing LF to HF values Statistical analysis was done with paired student's t-test.

Results and Discussion: Mean arterial pressure significantly decreased during anaesthesia induction in all groups while there was no significant change in heart rate during the study. In groups I and II, LF, HF and the LF/HF ratio significantly reduced by anaesthesia induction. In groups III and IV, although LF and HF reduced significantly by induction, the LF/HF ratio did not change significantly. During maintenance of anaesthesia significant reduction in LF and HF values continued in all groups, also the LF/HF ratio decreased significantly in all groups except group III. The reduced HRV values increased to baseline in a shorter time during the recovery period in groups III and IV HF values increased significantly with Mg infusion only during surgical incision in group II.

Conclusions: Isoflurane anaesthesia which did not cause a significant change in the LF/HF ratio had an advantage in respect of preserving sympathovagal balance and having a shorter recovery period. Mg infusion had no significant effect on HRV.

A.206 Heart rate variability: monitoring of autonomic nervous system activity during general anaesthesia

W Płazak, T Muszyński, A Macheta, H Podziomy, J Łach, P Podolec, K. Potocka-Płazak, J Andres *Department of Anaesthesiology and Intensive Care, Collegium Medicum of the Jagiellonian University, Cracow, Poland*

Background: The monitoring of the heart rate variability (HRV) is a new, non-invasive method of the autonomic nervous system activity assessment LF (low frequency, 0.055–0 09 Hz) is an index of adrenergic activation, HF (high frequency, 0.1–0 4 Hz) is an index of cholinergic activation and TD (total density, 0.0033–0 5 Hz) is an index of total autonomic activity

Goal of Study: To examine changes in adrenergic and cholinergic activity during general anaesthesia by intraoperative HRV monitoring

Material & Methods: 21 patients, 17–72 years old (mean 40 5) without cardiovascular disturbances, who underwent operations on the facial cranium due to neoplasmic changes were anaesthetised using thiopental and suxamethonium for induction and nitrous oxide with fentanyl for maintenance of anaesthesia. HRV indexes were calculated from 5-minutes fragments of recorded ECG in Del Mar® Avionics Holter Analysis Systems software. To estimate the level of statistical significance t-Student's test was used.

Results: We observed the decrease of LF, HF and TD values during maintaining of anaesthesia and an intensive increase of LF and TD values during extubation of patients (see table, the difference between preoperative value.

Examined period of anaesthesia	LF [ms^2/Hz]	HF [ms^2/Hz]	TD [ms^2/Hz]
Before the operation	346 4	1350 1	5794 8
During induction and intubation	342 5	564 6	4560 5
After intubation	42 8***	136 7**	4142 7
During the operation	22 3***	46 2**	1112 3**
During deduction	187 1	616 4	8260 9
During extubation	1433 6*	3130 1	19911 6**
5 minutes after extubation	592 4	1603 9	17182 3

*p < 0 05, **p < 0 01, ***p < 0 001

Discussion: The decrease of autonomic system activity during maintaining of anaesthesia could be a consequence of nitrous oxide inhalation and barbiturates and opioids injections Increase of HRV indexes during extubation depends on mechanical trauma and anticholinesterase drugs injected during deduction of anaesthesia

Conclusions: Induction and maintenance of general anaesthesia suppress the autonomic system activity Extubation is followed by strong activation of autonomic nervous system

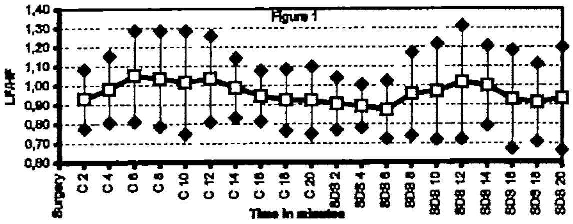
A.207 Effect of sandostatin on heart rate variability during anaesthesia and surgery

A. Petru, G. Kochiadakis[1], F Kanakoudis, D Michaloudis *Dpt of Anaesthesia and [1]Cardiology Clinic, University Hospital of Heraklion, Crete, Greece*

Background and Goal of Study: Heart Rate Variability (HRV) monitors the fluctuations of autonomic nervous system outflow to the heart as well as the balance between it's components (sympathetic and parasympathetic).[1] Intravenous Sandostatin (SDS, an analogue of the neuropeptide somatostatin) has been reported to produce transient bradycardia followed by systemic and pulmonary hypertension of very short duration [2] This study attempts to enlighten the mechanisms of this effect in humans during anaesthesia and surgery by power spectral analysis of Heart Rate Variability.

Materials & Methods: With the approval of the hospital's Ethical Committee, 10 patients who were to undergo surgery under total intravenous anaesthesia (TIVA) supplemented by nitrous oxide, entered the protocol of this study after signing informed consent All patients were of good physical status (ASA I), aged between 18–50 years A Holter machine was attached to the patients before induction to anaesthesia for subsequent off line HRV analysis They received TIVA with propofol (after Robert's scheme) and sufentanil infusions (0 5 μg/kg/min), cis-atracurium for muscle relaxation and mechanical ventilation with 60% nitrous oxide in O_2 (TV 8 ml/kg, RR. 15 bpm) After surgery begun, and anaesthesia was deep enough to accomplish stable haemodynamics for at least 10 minutes, a control recording of 20 minutes was marked on the Holter recording. By the end of this period, every patient received a slow bolus intravenous infusion of SDS 3.5 μg/kg in 20 ml normal saline. A second 20 minutes test period was marked on the Holter recording. During these 40 minutes, heart rate (HR), systolic (SAP) and diastolic (DAP) blood pressures were recorded manually. Statistical analysis was performed by using one way or two way ANOVA tests as required.

Results & Discussion: After SDS administration a statistically significant bradycardia was recorded ($p < 0.05$) followed by an increase in arterial pressure ($p < 0.05$) Meanwhile, HRV indices ratio (LF/HF, Figure 1, values are in mean ± SD, C = Control period, SDS = Sandostatin) did not change significantly, indicating no change of autonomic tone balance. Probably SDS activates somatostatin receptors in the heart and the peripheral and central vasculature or other reflex mechanisms that in either case do not affect autonomic nervous system balance.



Conclusions: Intravenous administration of Sandostatin during anaesthesia and surgery produces significant haemodynamic alterations without affecting the autonomic nervous system as expressed in Heart Rate Variability power spectral analysis.

A.208 Autoregulation of inner ear blood flow during propofol and isoflurane anaesthesia in middle ear surgery

M.P. Preckel[1], C Ferber-Viart[3], C. Dubreuil[2], R. Duclaux[3], C.S. Degoutte[2], J C Granry[1], V. Banssillon[2]. [1] *Service d'anesthesie-réanimation, CHU, 49033 Angers,* [2] *Service d'anesthesie-réanimation et d'Otorhinolaryngologie, Hospices Civils de Lyon, 69495 Pierre-Benite;* [3] *Explorations neurosensorielles, UCLB-UPRESA 5020, Mécanismes et perception auditifs, 69495 Pierre-Benite, France*

Background and Goal of the Study: Controlled hypotension was used to have a bloodless cavity during middle ear surgery under optic microscope. No study assessed the effect of controlled hypotension on the inner ear blood flow (IEF) in humans IEF autoregulation was described in several studies (1) As isoflurane impaired cerebral blood flow autoregulation, we hypothesized that isoflurane impaired IEF autoregulation. The purpose of this study was to compare the effect of isoflurane on IEF autoregulation to propofol during controlled hypotension in 20 patients ASA 1

Method: After approval from the Institutional Ethics Committee and written informed consent, patients were randomly divided in two groups to receive either propofol or isoflurane Anaesthesia was induced with alfentanyl 0.03 mg kg^{-1} and propofol 3.5 mg kg^{-1} and tracheal intubation was performed. Then the anaesthesia was either propofol (9 mg kg^{-1} h^{-1}) or isoflurane (end-expiratory concentration adjusted to 0 9–1.1%) with alfentanyl (0 01 mg.kg^{-1}.h^{-1}) IEF and mean arterial pressure (MAP) were measured continuously. IEF was measured by laser Doppler flowmetry (2) Controlled hypotension was realized by the infusion of sodium nitroprusside (0 21 ± 0.04 mg.kg^{-1} h^{-1}) to decrease MAP by 20–50%. To quantify autoregulatory aspect of IEF responses to hypotension, a coefficient of autoregulation (G_a) was calculated. A G_a value of 1 implies perfect autoregulation.

Results: The patients characteristics did not differ significantly among the 2 groups. During controlled hypotension, MAP decreased by 50 ± 3% in propofol anaesthesia and by 58 ± 3% in isoflurane anaesthesia without difference between the group. The coefficient of autoregulation Ga was significantly higher during propofol anaesthesia (0.62 ± 0.03) than during isoflurane anaesthesia (0 22 ± 0.03, $P < 0.0001$).

Conclusion: To sum up, isoflurane has a greater propensity than propofol to decrease the capacity of the inner ear to maintain blood flow autoregulation during controlled hypotension in middle ear surgery Further studies are needed to explore the auditory consequences of IEF autoregulatory capacity loss during controlled hypotension in middle ear surgery.

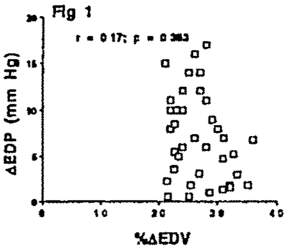
A.209 Descending limb of the Frank-Starling curve: reality or myth?

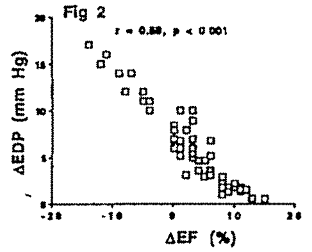
Stefan G De Hert. *Dep. Anesthesiology, University Hospital Antwerp, Belgium*

Background: Existence of the Frank-Starling mechanism in the failing human heart is a point of debate (1, 2). Especially, the presence of the descending limb is not accepted in clinical pathophysiology (3) The present study evaluated the Frank-Starling mechanism in anesthetized patients during coronary surgery (CABG).

Methods: Patients ($n = 50$) with preoperative ejection fraction >40% were included. LV pressures were measured with a fluid-filled catheter inserted in the LV cavity. A transesophageal ultrasound probe was positioned at the midpapillary level. Paced heart rate was 90 beats/min. LV pressures and echocardiographic images were recorded during leg elevation, which enhanced venous return to the heart and increased preload. Hemodynamic data, echocardiographic volumes and ejection fraction (EF) were analyzed before and at the end of leg elevation. Correlations were calculated using Pearson's correlation coefficient.

Results: Leg elevation induced a homogenuous increase in end-diastolic volume (EDV) The increase in end-diastolic pressure (EDP) was highly variable and unrelated to the increase in EDV (Fig 1) ($r = 0.17$, $p = 0\ 363$) The changes in EDP induced by leg elevation were not related to baseline values of EDP ($r = 0\ 32$, $p = 0.135$). A close inverse relationship was observed between changes in EDP and changes in EF ($r = 0\ 89$; $p < 0.001$). Patients with a limited increase in EDP showed an increase in EF. Patients with a marked increase in EDP showed no change or even a decrease in EF (Fig 2) A similar inverse relationship was shown between changes in EDP and changes in dP/dtmax ($r = 0\ 841$; $p < 0.001$)





Conclusions: The present findings indicate that patients undergoing CABG could be both on the ascending but also on the descending limb of the Frank-Starling curve A position on the descending limb was not due to impaired baseline diastolic function. Further research will have to elucidate if this phenomenon is due to impaired contraction-relaxation coupling and impaired contractility or to preload-induced diastolic dysfunction

A.210 A comparison of the effects on heart rate and blood pressure during and after anaesthesia with induced hypotension using glyceryl trinitrate alone or labetalol alone

A.A. van den Berg. *Department of Anaesthesia, King Khaled Eye Specialist Hospital, Riyadh, Saudi Arabia*

Introduction: Glyceryl Trinitrate (GTN) given to induce hypotension during anaesthesia may cause an increase in heart rate (HR) [1], and labetalol given during surgery induces slowing of HR, which continues into the recovery period [2] The clinical relevance of these assertions were tested during anaesthesia with induced hypotension for tympanoplasty.

Methods: With patient consent and Ethical Committee approval 54 healthy adults were randomised to receive GTN or labetalol Anaesthesia was strictly standardised from premedication, through maintenance with isoflurane 2% and controlled ventilation to tracheal extubation After induction of anaesthesia, hypotension (mean arterial pressure [MAP] 50 to 65 mmHg) was induced with either GTN IV infusion (50 mgs in 500 mls dextrose saline) or labetalol IV injection (1 mg.kg^{-1}) augmented during surgery, if necessary, with esmolol (2.0 mg.kg^{-1}) or GTN (0.01 mg kg^{-1}), respectively HR/SAP was recorded before induction, after induction, every 15 mins during surgery and every 5 mins during recovery. Analysis used

ANOVA, Chi^2 and 't' tests ($p < 0.05$ significance). Mean values of all preoperative (N_1) HR's and SAP's were compared with all intraoperative (N_2) and recovery (N_3) recordings

Results: Test groups (N = 27 each) were comparable. During surgery HR/MAP were reduced by both agents, but more so with labetalol

	Preoperative			Intraoperative			Recovery		
	N_1	HR	MAP	N_2	HR	MAP	N_3	HR	MAP
GTN	27	87	93	129	79*	65*	176	90	79*
Lab	27	88	92	133	69*	58*	186	74*	79*
p	–	ns	ns	–	<0 001	<0 001	–	ns	<0 001

* < 0 001 versus preoperative mean Data given as mean

During recovery, HR returned to preoperative levels with GTN but remained slower with labetalol; MAP was the same in both groups.

Conclusion: Hypotension induced using GTN infusion is not accompanied by clinically relevant change in HR during or after surgery. Hypotension induced with labetalol during surgery does not persist during recovery, and is not accompanied by clinically relevant bradycardia during or after surgery

A.211 Influence of dantrolene sodium on myocardial reperfusion injury after regional ischaemia in the rabbit heart *in vivo*

B. Preckel, T Comfère, V Thämer, W Schlack[1] *Physiologisches Institut I and [1] Institut für Klinische Anaesthesiologie, Heinrich-Heine-Universität, Postfach 1010 07, 40001 Dusseldorf, Germany*

Background & Goal of Study: Dantrolene sodium is a direct muscle relaxant which reduces calcium release from sarcoplasmic reticulum in skeletal muscles Intracellular calcium overload during ischaemia or reperfusion constitutes a primary cause of myocardial reperfusion injury. In isolated rat hearts, dantrolene sodium offered small protective effects against myocardial reperfusion injury (1) The aim of the present study was to investigate whether dantrolene sodium can reduce myocardial reperfusion injury after regional myocardial ischaemia in the rabbit heart *in vivo*

Materials and Methods: Eighteen chloralose-anaesthetized rabbits were subjected to 30 min occlusion and 180 min reperfusion of a major coronary artery. Left ventricular pressure (LVP, tip-manometer), cardiac output (CO, ultrasonic flowprobe), and infarct size (triphenyltetrazolium staining) were determined During the last five minutes of ischaemia, nine rabbits received 10 mg/kg dantrolene sodium intravenously (DAN). Another nine rabbits received the vehicle (DMSO) and served as controls (CON) Statistical analysis was done by Student's *t*-test.

Results: Baseline values were similar between groups (CON vs DAN: LVP, 99 ± 6 (mean ± SEM) vs 91 ± 6 mm Hg, P = 0.29, CO, 252 ± 26 vs 275 ± 23 ml min^{-1} P = 0.53). During coronary artery occlusion, LVP and CO were reduced to a similar extent in both groups (CON· LVP, 89 ± 3% of baseline values; CO, 90 ± 5%). After infusion of dantrolene sodium or the vehicle, there was a transient increase in CO to 108–113% of baseline values during the first 15 min of reperfusion. LVP did not recover to baseline values during reperfusion in both groups (CON vs DAN after 3 h 51 ± 5% vs 67 ± 7% of baseline, P = 0.10). Infarct size was 41 ± 4% of the area at risk in controls compared with 37 ± 6% in dantrolene sodium treated hearts (P = 0 59)

Conclusion: Dantrolene sodium does not attenuate myocardial reperfusion injury after regional myocardial ischaemia in the rabbit heart *in vivo*, when given at a clinically relevant concentration

A.212 Effect of propofol on reperfusion injury in the isolated rat heart

D. Ebel, T. Comfère, B. Preckel, V. Thamer, W. Schlack[1] *Institute of Physiology, [1] Institute of Anaesthesiology of the Heinrich-Heine-University of Dusseldorf, Postfach 10 10 07, D-40001 Dusseldorf, Germany*

Background and Goal of Study: Intracellular calcium level and free oxygen radicals play an important role in development of myocardial reperfusion injury The intravenous anaesthetic propofol inhibits calcium influx across plasma membranes as well as calcium release from the sarcoplasmic reticulum (1), and is known to scavenge free oxygen radicals (2). Therefore, we investigated the effects of propofol on reperfusion injury in the isolated rat heart

Material and Methods: Isovolumetric beating rat hearts were retrogradely perfused (Krebs-Ringer solution) at a constant pressure of 100 cm H_2O Heart rate was kept constant at 370 beats min^{-1}. The left anterior descending coronary artery (LAD) was occluded for 30 min and reperfused for 2 h. In the treatment group, propofol dissolved in intralipid was added to the perfusate during the last 5 min of occlusion and the first 15 min of reperfusion period in order to achieve a final concentration of 1 μg propofol and 1 μl intralipid per ml perfusate In a second group, only intralipid, the vehicle of propofol, was added A third group served as untreated controls (each group n = 12) We measured left ventricular developed pressure (LVDP), dP/dt, and coronary flow (CF). Infarct size (IS) was determined by triphenyltetrazoliumchloride staining. Statistics were performed by ANOVA followed by Dunnett's post hoc test

Results: Baseline values of LVDP (129 ± 4 mmHg, mean ± SEM), dP/dt_{max} (4228 ± 139 mmHg s^{-1}), and CF (12 2 ± 0 3 ml min^{-1}) were similar in all groups LAD occlusion reduced LVDP to 28 ± 2%, dP/dt_{max} to 38 ± 2%, and CF to 45 ± 2% of baseline values During reperfusion, the values recovered to 77 ± 3%, 78 ± 3%, and 97 ± 2%, respectively. There were no differences in haemodynamics between the three groups during occlusion and reperfusion. Propofol had no effect on IS when compared with the intralipid group (25 0 ± 3 7% *vs* 26 9 ± 3 3% of the area at risk, P = 0.89). However, when compared with the untreated controls, IS in the intralipid group tended to be smaller (26.9 ± 3 3% *vs* 34 8 ± 3.2%, P = 0.19)

Conclusion: Given at a clinically relevant concentration, propofol provides no protective effect on myocardial reperfusion injury in rat heart *in vitro* Intralipid might have a small cardioprotective effect during reperfusion, possibly by an oxygen radical scavenging effect (2)

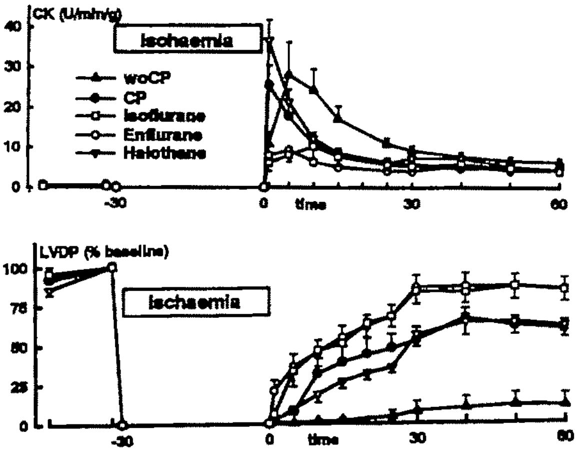
A.213 Influence of inhalational anaesthetics on myocardial reperfusion injury after cardioplegic arrest in the isolated rat heart

B. Preckel, V. Thamer, W. Schlack[1]. *Physiologisches Institut I and [1] Institut fur Klinische Anaesthesiologie, Heinrich-Heine-Universität Dusseldorf, Postfach 10 10 07, 40001 Dusseldorf, Germany*

Background & Goal of Study: Previous studies have demonstrated that inhalational anaesthetics can protect against myocardial reperfusion injury in vitro as well as in vivo The aim of the present study was to investigate whether halothane, enflurane and isoflurane offer additional protection when given during reperfusion after cardioplegic arrest (CP)

Materials and Methods: Using a Langendorff-preparation, isovolumetric beating rat hearts were perfused with a modified Krebs-Ringer solution (KRS) at a constant flow (11 ml/min) and paced at a rate of 370 beats per minute. Left ventricular developed pressure (LVDP) and creatine kinase release (CKR) were determined as indices of myocardial performance and cellular injury, respectively. After cardioplegic arrest (2 min Bretschneider-cardioplegia, 2 ml/min), the hearts underwent 30 min of warm ischaemia (38.5°C), followed by 60 min of reperfusion In the treatment groups (each n = 9), a saturated solution of either halothane, enflurane, or isoflurane in KRS was infused during the first 30 min of reperfusion in a concentration equivalent to 1.5 MAC in rats 9 additional hearts underwent the same protocol without inhalational anaesthetic (CP), 7 hearts underwent the protocol without cardioplegia and without anaesthetics (woCP) Statistical analysis was done by ANOVA followed by Dunnett's test as post hoc test

Results:



Conclusion: Enflurane and isoflurane improved functional recovery and reduced CK release even after myocardial protection by cardioplegia, while in halothane treated hearts, CK release and functional impairment were similar to controls The differences between the substances suggest different mechanisms of protection.

A.214 Hyperoxic lung injury and lung free radical metabolism in rats; the effects of N-acetylcysteine

Pınar Durak, Gulhan Ozgen, Ayşegul Ayyıldız, Sevda Muftuoğlu, Sema Kultufan, Esin Aşan, Orhan Canbolat, Sevim Ebil *Turkiye Yuksek Ihtisas Hospital, Hacettepe and Ankara University of Medical Schools/Ankara, Turkiye*

Background and Goal of Study: Oxygen free radicals released during hyperoxia may contribute to lung injury The aim of this study was to investigate the relation between hyperoxic condition and lung free radical metabolism and to establish a possible protective role of N-acetylcysteine (NAC) against to this condition.

Materials and Methods: All the experimental procedures were reviewed and approved by the animal care and use committee of the institution. Twenty-eight male adult wistor rats were used in the study. Rats divided into four groups. Oxygen (100%) was given to animals for 24 hours for three days. Animals were treated with 1 mg/kg p o NAC for three days All the rats were anesthetized with 90 mg/kg ketamine. The lung tissues were taken for biochemical and histo-pathological examinations Catalase (CAT) glutathione peroxidase (GSH-Px), superoxide dismutase (SOD), activities were measured As a peroxidation index, the malondialdehyde (MDA) concentration was determined Also, light microscopy were performed. As for statistical analysis Mann Whitney-U test was used. $P < 0.05$ was considered statistically significant

Results and Discussion: CAT activity was higher in the oxygen, NAS and oxygen + NAS groups than in controls ($p < 0\ 05$) There was not any significant difference between mean activity values of the GSH-Px enzymes. SOD activity was lower in the oxygen group than in control group ($p < 0.05$). There were, however no significant difference in SOD activities of control group and of NAS, NAS + 02 groups. MDA concentrations of NAS and NAS + 02 groups were higher than 02 and control group ($p < 0.05$). There were no significant difference in MDA concentration of 02 group and of control group. Light microscopy indicated structural changes in the lung cells of oxygen, NAS and also NAS + oxygen groups compared with control group. CAT, GSH-Px and SOD are the primary intracellular, antioxidant defense mechanism to cope with oxidant stress (1). It is possible that NAC could scavenge the active oxygen species directly by nonenzymatic reduction (2). The Interaction of NAC with 02 or OH would lead to the formation of N-acetylcysteine disulfide, with the intermediate formation of the thiyl radical The significance and reactivity of such a radical is unknown (3) Our results showed that NAC + 02 increased malondialdehyde levels in the lung tissues. The increase in catalase activity may occur as a compensatory mechanism against increased free radical metabolism.

Conclusion: It is concluded that NAC treatment cannot be used safely in the preventation of peroxidative damage caused by oxygen.

A.215 Effects of isoflurane and halothane on hepatic blood flow and sinusoidal microcirculation in the presence of hypoxia

K -F Klotz, C Tsunoda, R. Nakagawa, K. Wagner *Department of Anaesthesiology, Medical University of Luebeck, Germany*

Background and Goal of the Study: The effect of volatile anaesthetics on liver blood flow has been reported controversially In the literature In addition, the influence of hypoxia on liver macro- and microcirculation under inhalational anaesthesia is not completely understood Therefore, the purpose of the present study was 1) to examine the effects of isoflurane (ISO) and halothane (HAL) on hepatic blood flow at different concentrations in the presence of hypoxia and 2) to investigate hepatic sinusoidal microcirculation during inhalational anesthesia.

Methods: Female Sprague-Dawley rats (n = 6 per group, b.w. 255 ± 62 g) were anaesthetized with pentobarbital and ketamine. After tracheostomy rats were ventilated artificially with O_2 enriched air. Carotid artery and jugular vein were cannulated for blood pressure (MAP) monitoring, blood gas analysis and infusion. Ultrasound flow probes were placed around the aortic arch (cardiac output = CO), portal vein (PVF) and hepatic artery (HAF). Liver surface was observed by videomicroscopy and velocity of FITC labeled RBC was evaluated offline. Protocol ISO and HAL 0.5, 1.0, 1.5, and 2.0 MAC in normoxia (P_aO_2 126 ± 33 mmHg) and hypoxia (53 ± 11 mmHg). Data analysis was performed by one way ANOVA with Fisher's post hoc test ($p < 0\ 05$) and Student's T-test as applicable.

Results and Discussion: In ISO the relative portion of HAF from CO tended to decrease with increasing MAC in normoxia whereas the relative portion of PVF and total hepatic flow (THF) from CO remained unchanged RBC sinusoidal velocity showed no significant changes with different MAC in normoxia or hypoxia In ISO absolute values of hepatic blood flow remained unchanged in both normoxia and hypoxia but in HAL hepatic blood flow decreased dose dependently and except for HAF in hypoxia they were significantly different from value at 0 MAC and significantly lower as compared with those in ISO Percent changes of RBC velocity from 0 MAC were similar at 1 5 MAC in both normoxia and hypoxia of ISO (−25 0%). But at 1.5 MAC in HAL it was significantly lower in hypoxia compared with normoxia (−55.7% versus −32 9%) and in hypoxia it was significantly lower in HAL than that of ISO

Conclusion: ISO preserves hepatic macro- and microcirculation as compared with HAL both in normoxia and hypoxia.

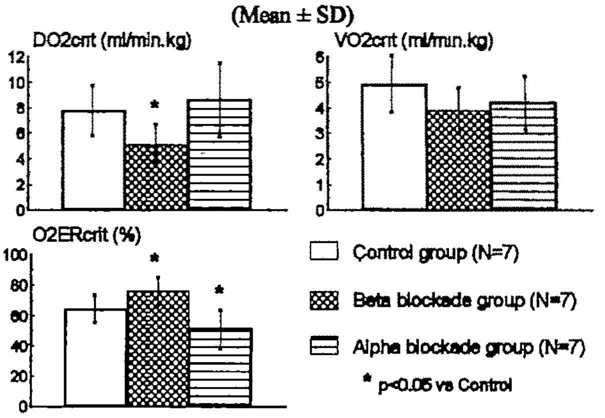
A.216 Tissue of oxygen extraction during ketamine anaesthesia in dogs: effects of sympathetic blockade

P Van der Linden, D. Schmartz, F. De Groote, N Mathieu, H. Zang *Dept Anaesthesiology, Erasme University Hospital, Brussels, Belgium*

Background and Goal of Study: We tested the hypothesis that sympathetic blockade, and more precisely alpha adrenergic blockade will decrease tissue O2 extraction capabilities during haemorrhage in ketamine anaesthetized dogs

Material and Methods: Twenty-one mongrel dogs (25.5 ± 3.7 kg) were anaesthetized with ketamine (5 mg/kg + 0 2 mg/kg.min) and pancuronium (0 1 mg/kg + 2 mg/h) and mechanically ventilated with air (PaCO2 35–40 mmHg). 30 min after splenectomy, the animals were randomized in three groups. Dogs received IV propranolol (2 mg/kg) in the first group (Beta group; N = 7); IV phenoxybenzamine (3 mg/kg) in the second group (Alpha group; N = 7), or served as control in the last group (Control group, N = 7) 30 min after administration of the studied medication, dogs were progressively haemorrhaged by successive withdrawals of 5 ml/kg of blood At each step, Oxygen delivery (DO2) and oxygen consumption (VO2) were measured after a 10 min period to achieve a new steady-state. VO2 was directly measured using an infrared CO2 analyzer and a paramagnetic O2 analyzer DO2 was calculated from thermodilution cardiac output and arterial O2 content. In each dog, critical DO2 (DO2crit) and VO2 (VO2crit) were obtained from a plot of VO2 vs DO2, as the point of intersection of the two best fit regression lines determined by a least sum of squares technique (1) Critical 02 extraction (O2ERcrit) was the ratio of VO2crit on DO2crit. Data obtained at critical point were compared using a one way analysis of variance, followed when indicated by a Tukey HSD test.

Result:



Conclusions: In the conditions of our study alpha adrenergic blockade is associated with a decrease in tissue O2 extraction capabilities, while beta adrenergic blockade is associated with an increase in tissue O2 extraction capabilities

A.217 Depressive effect of alfentanil on isolated human atrial muscle

S. Ünver[1], K. Derici[2], S Ebil[1], E.D. Yılmaz[2]. [1]*Turkiye Yüksek Ihtisas Hospital, Anaesthesia Clinic;* [2]*Medical Faculty of Ankara University, Department of Pharmacology, Sıhhiye, Ankara, 06100, Turkey*

Background and Goal of Study: The synthetic narcotic alfentanil have been used widely in anaesthesia, because cardiovascular stability can be maintained with in the high doses However it has been observed that alfentanil caused transient cardiac stimulation in intact dog and (+) inotropic and (−) chronotropic effect in isolated rabbit heart. Clinically bradycardia or sinus arrest could be appeared by fentanyl-derived analgesics which has been attributed to increased vagal tone The purpose of this study was to define the direct effects of alfentanil on the isolated human atrial muscle.

Materials and Methods: This study was approved by the Hospital Ethical Committee. Atrial tissues from seven male patients during coronary artery bypass operation were studied All patients received similar anaesthetic and anaesthesia was induced using fentanyl and diazepam with pancuronium and maintained using fentanyl and pancuronium During atrial canulation a small piece of the atrial tissue was removed and stored in cold solution and immediately transported to the laboratory. None of the patients received inotropic support before the atrial tissue was removed. Atrial tissue was cut strip (1–2 mm wide and 8–10 mm long) and suspended in organ bath containing Krebs solution at 37°C and gassed with 95% O_2 and 5% CO_2 mixture and isometric contractions were recorded The atrial strip was stimulated electrically with a square-wave DC impulse at 1 ms duration and 1 Hz.

Results and Discussion: Alfentanil caused concentration-dependent inhibition of contraction of isolated human atrial strips

Alfentanil (M)	10^{-10}	10^{-9}	10^{-8}	10^{-7}	10^{-6}	10^{-5}	10^{-4}
% Contraction (mean)	95 8	89 5	86 1	84 6	68 8	63 1	50 1
S E M	3 9	4 6	6 6	8 3	13 8	14 7	20 4

This study showed that alfentanil in high concentration caused depression of cardiac contraction in human heart

Conclusion: It could be suggested that adjustment of anaesthetic dose of the alfentanil in clinic application is very important and application of the high dose alfentanil should be avoided

A.218 Effects of midazolam and flumazenil in isolated rabbit hearts

T Ozturk[1], Y. Tuncok[2], H Guven[2], S. Kalkan[2], G Aran[3] [1]*Dept. of Anaesthesiology, Izmir Chest Diseases and Surgery Training Hospital;* [2]*Dept of Pharmacology, Dokuz Eylul Faculty of Medicine and* [3]*Ataturk State Hospital, Izmir, Turkey*

Background: Midazolam, a short acting benzodiazepine, can cause an increase or decrease in contractile force of myocardium in a dose dependent manner (1) The goal of our study was to determine the effects of midazolam on contractile response and heart rate of isolated rabbit hearts and to investigate the reversal effect of flumazenil, a benzodiazepine antagonist

Materials and Methods: Isolated New Zealand rabbit hearts ($n = 5$ in each group) were perfused with Krebs Henseleit Bicarbonate buffer solution at a constant pressure of 55 mmHg according to the Langendorff method The heart rate (HR) and left ventricular pressure (LVP) were measured throughout a balloon inserted into the left ventricle and recorded via a pressure transducer After a stabilization period, hearts were perfused with midazolam with increasing concentrations of 0.5 to 50 μM (1 to 100 fold more than the clinically relevant concentrations respectively) After a 10 minute incubation period for each midazolam concentration, flumazenil (0.025 and 0.05 mg min^{-1}) was infused for 10 minutes concurrently with midazolam perfusion. A flumazenil infusion alone had no effect in LVP and HRs ($p > 0.05$) The statistical analysis was done by using ANOVA and student's t test

Results and Discussion: The 5, 10, 20, and 50 μM midazolam decreased LVP (13 4 ± 2 2, 18.9 ± 5 4, 33.6 ± 3 1 and 35.6 ± 4.7% of baseline, respectively) significantly ($p < 0\ 05$). HRs were also decreased with the concentrations of 10, 20 and 50 μM midazolam (13 1 ± 2 6, 20 1 ± 3 5 and 24 6 ± 3 2% of baseline respectively, $p < 0.05$) Flumazenil infusions had no effect on midazolam-induced decrease in LVP and HRs

Conclusions: Midazolam developed a dose related myocardial depressant effect in the isolated rabbit heart model However, these effects may not have been observed on LVP and HR in clinically relevant doses in humans Additionally, flumazenil had no reversal effect of midazolam-induced cardiac depression indicating that cardiac depressant effect of midazolam may not be via benzodiazepine receptors.

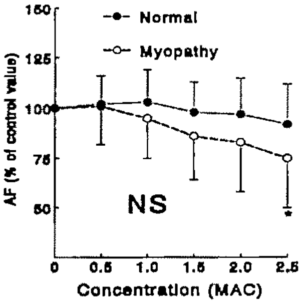
A.219 Myocardial effects of desflurane in hamsters with cardiomyopathy

B. Vivien, J L Hanouz, P. Conat, B. Riou. *Dept. of Anesthesiology, Pitié-Salpêtrière Hospital, Paris, France*

Background: The effects of desflurane on myocardial contraction and relaxation in diseased myocardium have not been completely understood

Material and Methods: The effects of equi-anesthetic concentrations of desflurane (0 5 to 2 5 MAC) on inotropy (isometric active force, AF) and lusitropy in left ventricular papillary muscles of normal and cardiomyopathic (strain BIO 14.6) hamsters were investigated *in vitro* (29°C, pH 7 40, Ca^{2+} 2 5 mM, stimulation frequency 3/min). Data are mean % of baseline ± SD.

Results: Desflurane had no significant inotropic effect in normal hamsters (AF at 2.5 MAC. 92 4 ± 20%, NS) In cardiomyopathic hamsters, desflurane induced a moderate negative inotropic effect (AF at 2 5 MAC 75 ± 25%, $P < 0.05$) Nevertheless, there was no significant difference between the two groups (Figure) After α- and β-adrenoceptor blockade or pretreatment with reserpine, the inotropic effect of desflurane was not significantly modified. This result contrast with that previously observed in the rat myocardium (1). In both strains, desflurane induced no lusitropic effect under low load or under high load



Conclusion: The myocardial effects of desflurane were not significantly different in normal and cardiomyopathic hamsters

A.220 Ischaemic preconditioning and tissue noradrenaline concentration in the rat heart

K. Dote, N. Adachi, T. Yorozuya, Y. Takasaki, S. Tsubota, T Fujitani, T. Arai. *Department of Anesthesiology and Resuscitology, Ehime University, Shigenobu, Ehime, 791–02, Japan*

Background: Ischemic preconditioning (IP) provides a significant cardioprotective effect against ischemic injury. Because the release of noradrenaline (NA) from sympathetic nerve endings during ischemia plays an important role in the extent of ischemic injury, we investigated the relation between the effect of IP and tissue NA level in the rat heart

Methods: The effect of IP, which is elicited by 3 cycles of 5 min of left coronary artery occlusion, was evaluated by comparing the infarct size of the myocardium with the area at risk after a subsequent 30 min of ischemia and 60 min of reperfusion The tissue concentration of NA in the left ventricle, the intraventricular septum, and the right ventricle during sustained ischemia was determined by using an HPLC-electrochemical detection The data from the infarct size and the NA concentration were analyzed by the Mann-Whitney test and the ANOVA with Bonferroni's adjustment, respectively

Results: IP reduced the infarct size (Con 56 ± 11% vs IP 16 ± 17%, Mean ± SD, $n = 6$, $P < 0\ 01$) The concentration of NA in the left ventricle gradually decreased after the onset of sustained ischemia, the effect being significant 60 min after ischemia (850 ± 66 ng/g before ischemia vs. 608 ± 117 ng/g 60 min after ischemia, Mean ± SD, $n = 6$, $P < 0\ 05$) The NA level in the right ventricle, in which ischemia was not induced, did not change during 60 min of ischemia Ischemic preconditioning did not exert an influence on the decrease of tissue NA level produced by 60 min of ischemia (Con 608 ± 117 ng/g vs. IP 597 ± 97 ng/g, Mean ± SD, $n = 6$, NS).

Conclusion: Ischemic preconditioning protected the heart in the histologic aspect, although it did not alter tissue NA level in the rat heart

A.221 Effects of hypertonic sodium solution in rat and rabbit myocardium: a mechanical and electrophysiological study

P. Ruel[1], M.-P. Sauviat[2], B. Riou[1], Y. Lecarpentier[2], P. Conat[1]. [1]*Departement d'Anesthesiology, CHU Pitié-Salpêtriere, Paris;* [2]*Unité INSERM 451, Palaiseau, France*

Background and Goal of the Study: Hypertonic sodium media (HS) has been advocated in the treatement of haemorrhagic shock But its inotropic effects remain debatable.r The goal of this study was to compare the inotropic effects of HS in rat and rabbit myocardium.

Materials and Methods: Ventricular papillary muscles from rat (n = 7) and rabbit (n = 1) hearts were both isolated and studied at 29°C in Krebs-Henseleit solution Ca^{2+} was at 0 5 mM (rat) and 2.5 mM (rabbit) with Na^{+} at 140 mM. The mechanical parameters were obtained with stimulation at 0 2 Hz (rat) and 0.3 Hz (rabbit) the maximum unloaded shortening velocity (Vmax), the maximum active isometric force (AF), the contraction-relaxation coupling under isotonic (R1) and isometric (R2) conditions, reflecting respectively the sarcoplasmic reticulum (SR) and the calcium myofilament sensitivity Data are expressed as mean % of control value ± SD. Transmembrane resting (RP) and action (AP) potentials were recorded on both rat (n = 12) and (n = 9) rabbit papillary muscles using intracellular microelectrodes technique (resistance 15–20 MΩ; tip potential less than ± 3 mV).

Results and Discussion: HS induced a negative inotropic effect in the rat (AF: 75 ± 8%, Vmax· 90 ± 10%) and a positive ,inotropic effect in the rabbit (AF: 122 ± 22%, Vmax· 116 ± 22%) Nevertheless R1 and Ré remain unchanged HS shortened the plateau duration of rat muscle. In rat, total replacement of Ca^{2+} by Sr^{2+} is known to lengthen the plateau and the AP duration (APD). In the presence of Sr^{2+}, HS significantly lengthened the APD. In rabbit, HS prolonged the plateau duration and the repolarizing phase of the AP Despite opposite inotropic effect of HS in rat and rabbit, Ca^{2+} uptake by the SR and Ca^{2+} sensitivity myofilament were not altered. HS lengthened the AP duration in rabbit suggesting that the Ca^{2+} influx has been increased and induced a positive inotropic effect. In rat, HS shortened the plateau duration and exerted a negative inotropic effect. But, in presence of Sr^{2+}, HS induced a lenghtening of the AP duration of rat mimicking the rabbit AP. This suggested that HS increased the Ca^{2+}-activated K^{+} current in this preparation Such an increase migth lead to a reduction of the Ca^{2+} influx via voltage-dependent Ca^{2+} channels and account for the negative inotropic effect of HS in rat heart muscle

Conclusion: HS induce opposite inotropic effect according to rat and rabbit. These differences may be explained by the HS action on the influx of Ca^{2+} during the action potential. $^{2+}$ influx

A.222 Acute potassium ion replenishment normalizes arrhythmia rate in chronic hypokalaemic rats *in vitro*

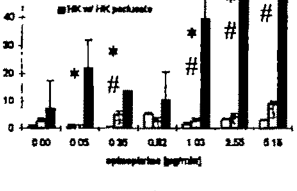
M Anetseder, G Mohiuddin[1], D.J. Miletich[1], N. Roewer. *Dept. of Anesthesiology, University of Würzburg, FRG; [1] Dept. of Anesthesiology, University of Illinois at Chicago, USA*

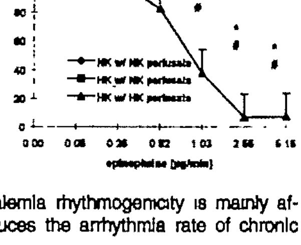
Chronic hypokalemia was shown to be a major risk factor for ventricular premature complexes[1]. Controversial is whether rapid K^{+} replenishment increases the risk of arrhythmia? Acute K^{+} replenishment on epinephrine induced arrhythmias was studied in isolated hearts of normal and chronic hypokalemic rats.

Methods: With IRB approval, isolated hearts of Sprague-Dawley rats (n = 6 per group) on [K^{+}]-free diet >3 weeks were perfused with hypokalemic ([K^{+}] 2 0 mM, HK-HK) or normokalemic ([K^{+}] 4.5 mM, HK-NK) Krebs solution. A normally fed control group was perfused with normokalemic (NK-NK) Krebs solution The hearts were mounted in a modified Langendorff-preparation with a leftventricular balloon (preload 2–12 mmHg, coronary perfusion pressure 70 mmHg/37°C). After equilibration, epinephrine was infused at 0.05, 0 25, 0.515, 1.03, 2.55 and 5 15 µg/min for 3 min each. Intraventricular pressure and heart rate were recorded. Posthoc the time of arrhythmias >5 sec duration was determined. For statistics, U-test by Mann and Whitney was used.

Results and Discussion: Serum [K^{+}] in chronic hypokalemic animals was significantly lowered ([K^{+}] 2.14 vs. 3.98 mM). Intraventricular pressures were 84–95 mmHg In hypokalemic hearts, the arrhythmia rate increased significantly with epinephrine and hypokalemic perfusate; it did not differ from normokalemic rats when perfused with normokalemic solution

Chronic hypokalemic rats have an increased disposition for major arrhythmias Acute K^{+} replenishment to 4.5 mM reduces arrhythmias to normal





Conclusion: With chronic hypokalemia rhythmogenicity is mainly affected. Acute K^{+} replenishment reduces the arrhythmia rate of chronic hypokalemic rat hearts to normal.

A.223 Haemodynamic effects of inhaled nitric oxide and intravenous milrinone in cardiac surgical patients with pulmonary hypertension

I. Rovira, G. Fita, M. Pacheco, P. Matute, M. Basora, A. Faull, C. Roux, C. Gomar. *Departament d'Anestesiologia, Hospital Clínic, Facultat de Medicina, Universitat de Barcelona, Spain*

Background and Goals of Study: Inhaled nitric oxide (NO) produces selective pulmonary vasodilation in cardiac surgical patients with pulmonary hypertension (PH)[1] The aim of the study was to investigate the haemodynamic effects of inhaled NO and intravenous milrinone, a phosphodiesterase III inhibitor, in patients with PH before cardiac surgery.

Patients and Methods: We studied 16 cardiac surgical patients with PH scheduled for valvular replacement and/or myocardial revascularization. After induction of anaesthesia measurements included: mean blood pressure (MBP), mean pulmonary artery pressure (MPAP), right atrial pressure (RAP), pulmonary wedge pressure (PWP), continuous mixed venous saturation (SvO2) and cardiac output (CO). Systemic and pulmonary vascular resistances (SVR and PVR), stroke index (SI) and oxygen delivery (DO_2) were calculated by standard formulae. Patients were randomized in two groups: group I (NO): received 20 ppm of NO inhalation and group II (MIL): received 0 5 $\mu g.kg^{-1}.min^{-1}$ of i.v. milrinone Measurements were made at baseline (BAS) and after 20 minutes of NO inhalation or milrinone infusion

Results and Discussion: Both NO and milrinone caused a significant reduction on MPAP, but only NO was selective for pulmonary vessels Furthermore, NO produced a greater reduction on MPAP, (−22%) compared to milrinone (−14%)

	Group I		Group II	
	BAS	NO	BAS	MIL
MBP (mmHg)	87 (18)	82 (19)	75 (2)	71 (4)*
MPAP (mmHg)	37 (6)	29 (6)*	35 (5)	30 (3)*
RAP (mmHg)	14 (2)	13 (3)	15 (3)	14 (3)
PWP (mmHg)	24 (5)	19 (3)	24 (3)	21 (3)
CO ($L\ min^{-1}$)	3 12 (0 8)	3 43 (0 8)	2.99 (0 6)	3 28 (0.8)
SVR ($dyn\ sec\ cm^{-5}$)	1855 (653)	1597 (436)	1688 (389)	1468 (463)
PVR ($dyn\ sec\ cm^{-5}$)	361 (149)	235 (93)*	335 (107)	207 (94)*
SI ($mL\ m^2$)	30 (10)	30 (9)	28 (5)	31 (9)
SvO_2 (%)	70 (12)	69 (8)	72 (6)	71 (7)
DO_2 ($mL\ min^{-1}$)	511 (149)	626 (225)	406 (79)	407 (94)

Mean (SD), * $p < 0.05$ compared with BAS value, t-test

Conclusions: Inhaled NO is more efective and selective than milrinone for treatment of PH in cardiac surgical patients

A.224 Demographic data of responders and non-responders to inhaled nitric oxide among patients with mitral valve stenosis

P. Knapik[1], M. Zembala[2], J. Puzlo[1], M. Knapik[1], G Juszczyk[1]
[1] Department of Anaesthesiology, Katowice; [2] Silesian Centre for Heart Disease, Zabrze, Poland

Background and Goal of the Study: Inhaled nitric oxide (NO) is increasingly used to test the vasodilator capacity of the vascular bed in various groups of patients with pulmonary hypertension. This may also potentially apply to patients with mitral valve stenosis, therefore we decided to find out, whether a response to NO was related to the initial demographic data in this group of patients.

Materials and Methods: After ethical committee approval and informed consent, we studied 26 patients scheduled for mitral valve replacement due to mitral valve stenosis, with a mean pulmonary artery pressure (PAm) greater then 30 mmHg. Arterial line and pulmonary catheter were inserted in local anaesthesia and 30 ppm NO in 100% oxygen was given for 15 minutes during spontaneous ventilation via a tightfitting face mask before induction of anaesthesia. Patients with a decrease of a PAm > 10% entered a "responders" group (R), while those with a decrease of PAm < 10% entered "non responders" group (NR). Demographic data of these groups were compared (t-test and Pearson's two-tailed test).

Results and Discussion: 10 patients entered NR group and 16 entered R group. Mean PAm decrease was 17.1% (from 4.3% to 36 5%). Patients in NR group had significantly lower weight and were more frequently classified NYHA IV. Other factors were not found to be significantly different in these groups (see table).

	R (n = 16)	NR (n = 10)	Signf
Sex (M/F)	7/79	2/8	NS
NYHA (IV/III)	7/9	9/1	0 03
Reoperative (Y/N)	1/15	3/7	NS
Age (years)	54 7 ± 10 84	56 3 ± 8 56	NS
Height (cm)	167 ± 7 9	162 ± 5 5	NS
Weight (kg)	68 5 ± 10 9	58 1 ± 9 16	0 02

Conclusion: In patients with mitral stenosis and pulmonary hypertension, "non-responders" to NO have significantly lower weight and are more frequently in heart failure.

A.225 Expression of endothelin receptors in the pulmonary circulation

J. Schmeck, S. Schmeck, A Heller, K van Ackern, T. Koch. *Dept. of Anaesthesiology and Op Int Care Medicine, Faculty of Clinical Medicine Mannheim, Univers of Heidelberg, FRG*

Introduction: Until now, the distribution of the receptor subtypes mediating pulmonary vascular reactions of endothelin-1 is still unclear Some investigators described ETA receptors as the predominantly expressed subtype in the pulmonary circulation [1] whereas ET_B receptor related vasoconstriction has also been reported [2] Aim of our study was to investigate the receptor subtypes which are expressed in the pulmonary circulation of the rat using polymerase chain reaction

Methods and Results: The experiments were performed on isolated pulmonary arteries of 6 rats (SD). Total RNA was extracted according to the method described by Chomczynski [3]. First-strand cDNA was synthesized incubating RNA (6 μg) at 42°C for 60 min with a mixture (10 μl) of Superscript II reverse transcriptase, 5xRT buffer 0.1 M DTT, 50 μM poly dT_{16}, and 10 mM each dNTP (dATP, dCTP, dTTP, dGTP) Thereafter the mixture was incubated 15 min at 75°C to stop the reaction For the PCR amplification, an aliquot (0.5 ml) of RT product was mixed with 25 mM $MgCl_2$, 10x PCR buffer, 10 mM dNTP, 10 pmol/μl of each sense and antisense primer in a volume of 30 μl. 1 unit of Taq DNA polymerase was added using hot start PCR technique The thermal cycle profile (35 cycles) used in this study was 1) denaturing for 1 min at 94°C, 2) annealing primers at 55°C for 1 min, 3) extending the primers for 1.5 min at 72°C. The sequences of the primers were· ET_As 5′TTCGTCATGGTACCCTTCGA3′; ET_Aas 5′GATACTCGTTCCATTCATGG3′; ET_Bs 5′TTCACCTCA GCAG GATTCTG3′, ET_Bas 5′AGGTGTGGAAAGTTAGAACG3′. A portion (10 μl) of the PCR product was electrophoresed in a 1% agarose gel in TAE buffer. The gel was stained with ethidium bromide and photographed. The integrity of the cDNA preparation was shown by GAPDH controls. In each preparation both ET_A and ET_B receptors were detectable.

Conclusions: The present results demonstrate that ET_A and ET_B receptors are expressed in rat pulmonary arteries mediating endothelin effects

A.226 Effects of endothelin-1 in the pulmonary circulation

J Schmeck, S Schmeck, A Heller, K van Ackern, T. Koch *Dept of Anesthesiology and Op Intensive Care Medicine, Faculty of Clinical Medicine Mannheim, Univers of Heidelberg, FRG*

Introduction: The effects of the vasoactive substance endothelin-1 (ET-1) in the pulmonary circulation are not completely understood. Pulmonary vasoconstriction [1] after ET-1 injection has been described but also vasodilation [2] Aim of the present study was to examine the effects of ET-1 in the isolated lung with respect to ET_A and ET_B receptor mediatled actions

Methods and Results: The experiments were performed on isolated rabbit lungs which were perfused with a cell and plasma free buffer solution The pulmonary arterial pressure (PAP) was continuously registered Intermittently perfusate samples were drawn to determine thromboxane A_2 (TXA_2) and prostacyclin (PGI_2) levels ET-1 injection (10^{-8} M, control; n = 6) resulted in an immediate increase in PAP (14.3 ± 0 8 mmHg at 20 min) which was followed by a second one 60 min thereafter leading to a final PAP of 28 6 ± 0.9 mmHg at 120 min The pressure reaction was paralleled by an increase in TXA_2 and PGI_2 levels. Pretreatment with the ET_A receptor antagonist LU135252 (10^{-6} M, n = 6) markedly reduced the PAP during the whole observation period ($p < 0.01$) and also reduced the generation of cyclooxygenase products ($p < 0.01$ at 30, 90 min, $p < 0\ 05$ at 120 min). In contrast to this, pretreatment with the ET_B receptor antagonist BQ788 (10^{-6} M, n = 6) amplified the immediate PAP increase after ET-1 injection (25 8 ± 1.1 mmHg after 20 min; $p < 0\ 01$ vs control) The PAP remained on this high level until the end of the observation period The generation of PGI_2 was reduced as compared to the other groups

Conclusions: The ET-1 induced vasoconstriction is mediated via the ET_A receptor subtype The generation of TXA_2 seems to play an essential role in the maintenance of the vascular reaction Since the blockage of ET_B receptors aggravates the PAP increase after ET-1 injection, it could be concluded that ET-1 limits his own vasoconstrictor effects by ET_B receptor related vasodilatory potency.

Acknowledgements: This study was supported by a grant from the Faculty of Clinical Medicine Mannheim, Univ of Heidelberg

A.227 Effect of halogenated and intravenous anaesthesia on hypoxic pulmonary vasoconstriction and cyclo-oxygenase and nitricoxide-synthase blockade

P. Ewalenko, S Brimioulle, S Deneu, S Pierre, R Naeije *Laboratory of Cardiovascular and Respiratory Physiology, Faculty of Medicine, Free University of Brussels, Brussels, Belgium*

Aim: HPV is better preserved with intravenous than volatile anesthesia and is enhanced by COX and NOS blockade We wondered whether iv L-NA (L) 10 mg kg^{-1} (NOS inhibition) and indomethacin (I) 2 mg.kg^{-1} (COX inhibition) differently affect HPV under inhalational or intravenous anesthesia

Methods: 16 dogs were anethetized in random sequence with sevoflurane 1 MAC (H) and propofol (P) 18 mg $kg^{-1}.h^{-1}$, in hyperoxia (FiO2 0 4) and hypoxia (FiO2 0 1) before and after I + L. Pulmonary hemodynamics was studied by multipoint pulmonary artery-left atrial pressure (Ppa-Pla) over cardiac index Q relationships and impedance (PVZ) spectra obtained from Fourier series for instataneous Ppa and Q

Results: Ppa-Pla/Q plots and PVZ were identical at baseline and after (I + L). Hypoxia-induced upwards shifts of pressure (*) were increased by I + L (§) and more with P than H (°) ZO (0 Hz impedance) and 1^{st} modulus Z1 were increased with hypoxia (*) and futhermore with I + L (§) PVZ spectra were not differently affected by anaesthesia Table & Figure· mean ± SE $p \leq 0\ 05$; * hypoxia, ° anest, § I + L Fig Ppa-Pla/Q plots

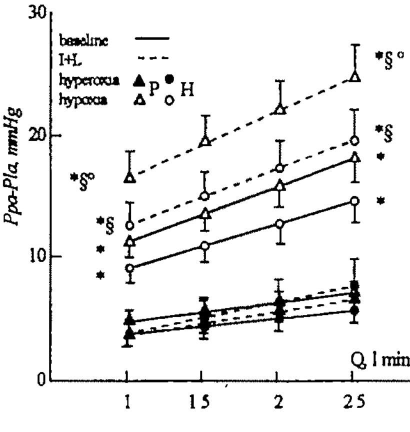

Table. ΔP (mmHg), Z0 and Z1 (dyn s cm^{-5}) at same Q

	I + L	Halogene		Propofol	
FIO2	0 4	0.1	0 4	0 1	
ΔP	before	6 ± 1	$14 \pm 2^{*}$	8 ± 1	$19 \pm 2^{*°}$
	after	6 ± 1	$17 \pm 2^{*§}$	6 ± 1	$25 \pm 3^{*§°}$
Z0	before	507 ± 38	$816 \pm 84^{*}$	518 ± 44	$834 \pm 7^{*}$
	after	859 ± 156	$1846 \pm 341^{*§}$	688 ± 93	$1480 \pm 232^{*§}$
Z1	before	58 ± 5	$92 \pm 10^{*}$	71 ± 8	100 ± 8
	after	85 ± 11	$148 \pm 19^{*§}$	84 ± 11	$152 \pm 19^{*§}$

Conclusion: In the intact dog, 1° basal pulmonary vascular tone is not modulated by I + L, 2° HPV is preserved with P and H, but attenuated with H, 3° HPV enhancement by I + L is maintained under P and H, but less with H and 4° hypoxia-induced increase in distal resistance and proximal elastance and/or wave reflection is increased with I + L

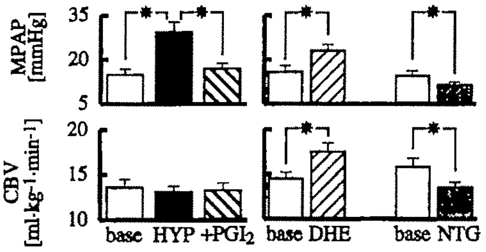
A.228 Pulmonary vascular tone does not affect central blood volume

T.W.L. Scheeren, G. Wietasch[1], J.O Arndt. *Institut f Experimentelle Anaesthesiologie, H.-Heine-University, Duesseldorf, [1]Klinik f. Anaesthesiologie und Spezielle Intensivmedizin, Universitat Bonn, Germany*

Background and Goal of Study: Most of the central blood volume (CBV) is held in non-contractile pulmonary vessels [1] Therefore, changes in pulmonary vascular tone should not be accompanied by changes in CBV To test this hypothesis we altered pulmonary vascular tone and systemic tone as well and measured CBV along with intravascular pressures

Materials and Methods: In 35 experiments on 5 anaesthetized (pentobarbitone) dogs we measured CBV as the product of cardiac output (thermodilution) and mean central transit time (Indocyanine green) The tracers were injected into the right atrium and the dilution curves recorded in the pulmonary artery and ascending aorta via fiberoptic thermistor probes. Transit times were calculated by deconvolution of the dye dilution curves [2]. Pulmonary vascular tone was altered by hypoxia (HYP, 10% O_2 in N_2) and aerosolized prostacyclin (PGI_2, 7.5 ng/kg.min), systemic vascular tone by dihydroergotamine (DHE, 7.5 μg/kg) or nitroglycerin (15 μg/kg min).

Results and Discussion: CBV remained constant despite marked changes in mean pulmonary arterial pressure (MPAP) during HYP and subsequent PGI_2 inhalation However, CBV followed the changes in MPAP induced by altering systemic vascular tone (fig. 1).



Means ± SEM ; * $p < 0.05$, t-Test, α-adjusted

Conclusion: Pulmonary vascular tone does not affect central blood volume, which however changes passively along with mean pulmonary arterial pressure when the blood distribution is altered by systemic vascular tone

A.229 Carbon dioxide reactivity in patients with sleep apnoea syndrome: a transcranial Doppler study

A.B. Ahmed, R.P. Mahajan. *University Department of Anaesthesia, University and City Hospitals, Nottingham NG7 2UH, UK*

Background and Goal of Study: Patients with sleep apnoea syndrome (SAS) are known to be at greater long-term risk of stroke and transient ischaemic attacks[1] possibly due to impaired cerebral autoregulation. In normal patients, cerebral blood flow changes linearly by 20% per 1 kPa change in end-tidal CO_2 ($FE'CO_2$)[2] We have examined this phenomenon in patients with SAS

Materials and Methods: We studied nine patients aged 18–65 who were diagnosed with SAS according to standard clinical criteria and measured their baseline $FE'CO_2$, heart rate, mean arterial blood pressure and mean cerebral blood flow velocity (CBFV). The measurements were repeated after a 1 kPa change in baseline $FE'CO_2$ in either direction Hypercapnia was achieved breathing 2.5% CO_2 in oxygen and hypocapnia was obtained by voluntary hyperventilation. The results were analysed using the Wilcoxon Rank Sum test and Kruskal-Wallis test and those reaching statistical significance are shown below

Results and Discussion:

	Hypocapnia mean (SD)	Baseline mean (SD)	Hypercapnia mean (SD)
$Fe'CO_2$ (kPa)	4.04 (0 39)	5.10 (0.39)	6 26 (0 40)
CBFV (cm s^{-1})	41 18 (11.62)*	49 70 (10 96)	72.82 (16 20)*
% change in CBFV.kPa^{-1}	19.27 (7 38)*	–	43 08 (27 31)*
Wilcoxon Rank *p*	0 008	–	0 008

*$p < 0\ 05$

Conclusions: In patients with SAS, hypercapnia is associated with exaggerated CO_2 reactivity when compared with hypocapnia ($p < 0\ 012$). This may be an early indication of loss of cerebrovascular tone in this group of patients

A.230 Packed cell volume variations in a rabbit model of arterial thrombosis and bleeding

B Ouaknine-Orlando, C M Samama, B. Riou, P. Conat *Dept of Anesthesiology., La Pitié Hosp., Paris, France*

Background and Goal of Study: Anaemia induces a lengthening of the bleeding time (BT). We have studied the role of haematocrit (Ht) variations in a Folts'model of experimental arterial thrombosis and bleeding

Material and Methods: 24 anaesthetised New Zealand rabbits were ventilated and continuously monitored for blood pressure, temperature, and carotid flow (electromagnetic flowmeter). Sequentially an injury and a stenosis (>60%) were carried out on the carotid artery, inducing thrombosis with cyclic flow reductions (CFR) recorded over a 20-min period. Animals were randomised into 3 groups. control (C), Platelet Rich Plasma (PRP) including a blood withdrawal (BW) followed by a compensation with rabbit homologous PRP, Whole Blood Retransfusion (WBR) including a BW substituted with a gelatin, followed by whole blood retransfusion At the beginning of the experiment and after each CFR period (CFR 1· before BW, CFR 2: after BW, CFR 3· after compensation with PRP or whole blood) blood samples (platelet count Pl, Ht, prothrombin time and fibrinogen), ear immersion BT and ex-vivo platelet aggregation test were performed At the end of the experiment, a laparotomy with a spleen section was done and the amount of wound bleeding (WB) was recorded. Data were expressed as mean ± SD except for CFR and WB (medians with extremes) – ANOVA

Results: In PRP and WBR groups, decrease in Ht abolished CFR, lengthened BT, and increased WB. Blood retransfusion in WBR group induced CFR reappearance, and BT shortening No change in prothrombin time or fibrinogen was observed

	C (n = 8)	PRP (n = 8)	WBR (n = 8)
CFR1 (n)	4 5 (3–6)	4.0 (3–10)	7 0 (3–13)
CFR2 (n)	4.0 (1–5)	0 0 (0–1)*	0 0 (0–0)*
CFR3 (n)	3 5 (0–6)	0 0 (0–1)*	4 0 (2–9)•
Ht 1 (%)	37 ± 4	36 ± 3	38 ± 3
Ht 2 (%)	36 ± 4	23 ± 2*	23 ± 2*
Ht 3 (%)	34 ± 3	22 ± 3*	31 ± 3•
Pl 1 (Giga/l)	243 ± 54	263 ± 82	317 ± 61
Pl 2 (Giga/l)	236 ± 60	235 ± 66	220 ± 66
Pl 3 (Giga/l)	211 ± 47	230 ± 65	240 ± 47
BT 1 (sec)	77 ± 25	76 ± 24	84 ± 37
BT 2 (sec)	76 ± 21	114 ± 36*	127 ± 29*
BT 3 (sec)	73 ± 28	118 ± 38*	114 ± 42*
WB (g)	6 (3–16)	9 (4–22)	13 (8–30)*

* $p < 0\ 05$ versus C-• $p < 0.05$ versus PRP

Conclusion: Decrease in Ht limits arterial thrombosis, and increases bleeding in the rabbit. Ht normalization induces a reappearance of thrombosis and BT shortening.

A.231 Intraoperative haemodynamic changes during open and laparoscopic adrenalectomy for phaeochromocytoma

D. Bernard, Y. Ozier, N Jude, Y. Chapuis[1], C. Conseiller. *DAR, Clinique chirurgicale, [1]Hopital COCHIN 75014 Paris, France*

Introduction: Surgical treatment of non malignant adrenal disorders is increasingly performed under laparoscopic approach (2). Both pneumoperitoneum and adrenal tumor manipulation may induce haemodynamic (HD) variations The aim of this study is to compare the HD effects of laparoscopic or conventional surgery for phaeochromocytoma

Methods: Between january 93 and february 97, 22 patients undergoing surgery for phaeochromocytoma have been compared: 11 laparoscopic transabdominal adrenalectomies (LA); 11 open transabdominal adrenalectomies (OA). HD data were retrospectively collected for each patient by a radial arterial line and a Swan Ganz catheter; included heart rate (HR), mean arterial pressure (MAP), central venous pressure (CVP), pulmonary capillary wedge pres-sure (PCWP) and cardiac index (CI) at 4 periods incision-insufflation (A), dissection (B); tumor excision (C), end of surgery (D). Systemic vascular resistances (SVR) and left ventricular work index (LVWI) were calculated. Maximal and minimal arterial systolic pressure (Max SAP, Min SAP) were recorded for each patient throughout the procedure Statistics: Student's t test (continuous data); chi-square test (qualitative data).

Results & Discussion: The 2 groups have no significant difference for: age, sex, size and side of the tumor, preoperative and intraoperative

A 231 Table

	A		B		C		D	
	LA	OA	LA	OA	LA	OA	LA	OA
HR bpm	72 ± 24	78 ± 19	94 ± 20	86 ± 21	90 ± 16	94 ± 26	87 ± 12	86 ± 21
MAP mmhg	105 ± 21*	86 ± 13	121 ± 32	114 ± 19	82 ± 10	78 ± 15	83 ± 15	84 ± 14
CVP mmhg	12 ± 4*	8 ± 3	14 ± 6*	8 ± 3	12 ± 6*	7 ± 3	10 ± 5	9 ± 2
PCWP mmhg	15 ± 3*	11 ± 4	20 ± 6*	12 ± 5	15 ± 7*	11 ± 2	13 ± 5	13 ± 6
CI 1/mn/m2	2 6 ± 1 3	3 1 ± 0 7	3 7 ± 1 3	3 9 ± 0 8	3 5 ± 0 9	4 ± 0 6	3 2 ± 1	3 7 ± 0 9
SVR dyn s/c m5	2442 ± 1212	2082 ± 786	1951 ± 1219	1805 ± 672	1315 ± 738	1264 ± 383	1156 ± 383	1493 ± 1418
LVWI g m/cm2	44 ± 22	48 ± 7	52 ± 15*	75 ± 23	39 ± 11	43 ± 14	40 ± 11	44 ± 12

* $p < 0\ 05$

used vasoactive drugs, blood volume expansion, urine output Results are shown in the tables.

	LA	OA
Max SAP mmHg	213 ± 23	215 ± 50
Min SAP mmHg	87 ± 14	86 ± 18

In LA group, significant HD variations are an increase of MAP (at incision period), CVP and PCWP (throughout all the laparoscopic period) Those variations have been reported by authors who studied HD in laparoscopic surgery (1) they are the circulatory response to pneumoperitoneum In fact, at the end of the procedure all the HD data are comparable in the 2 groups. We do not find any significant difference due to the tumor manipulation

Conclusion: This study shows that, for the HD standpoint, LA is an acceptable alternative to open adrenalectomy

RESPIRATION

A.232 Gas exchange and intrapulmonary shunting during liver transplant

G. Martínez-Pallí, J. Balust, J Beltran, E Zavala, M T Anglada, P Taurà, J Visa, J A. Barberà, R Rodriguez-Roisin *Liver Transplantation Unit and Pulmonary Medicine, Hospital Clinic, University of Barcelona, Barcelona, Spain*

Background: Up to now, severe hypoxemia is regarded as a contraindication for liver transplant (LTx) One of the causes of hypoxemia in cirrhotics is the so called hepatopulmonary syndrome (HPS) (defined as intrapulmonary vascular dilatations resulting in right-to-left shunting), that may reverse after LTx

Aim: To investigate pulmonary gas exchange during LTx and whether hypoxemic patients with HPS have a different postoperative course.

Patients and Methods: We studied 7 patients with HPS and 31 cirrhotic patients with normal PaO_2 (No-HPS) Arterial (a) and venous mixture (vm) blood gases were assessed after anesthetic induction; 20 min after breathing 100% O_2 and 20 min after breathing 21% O_2. We compared the postoperative time on mechanical ventilation, time on admission in ICU and number of pulmonary complications during postoperative period in both groups of patients. All data are presented as mean ± SEM Statistical analysis was performed using analysis of variance (ANOVA) with unpaired-t-test.

Results: Measurements of PaO_2, $PvmO_2$ and intrapulmonary shunt (Q_S/Q_T) were as follows·

	HPS		NO-HPS	
	21% O_2	100 O_2	21% O_2	100 O_2
PaO_2 (mmHg)	61 ± 19	437 ± 81$^+$	81 ± 19*	448 ± 109$^+$
$PvmO_2$ (mmHg)	41 ± 4	75 ± 5$^+$	39 ± 4	61 ± 10*$^+$
Q_S/Q_T (%)	51 ± 20	28 ± 9$^+$	23 ± 14*	27 ± 20

(* = $p < 0\ 05$ between 21–100% O_2, $^+$ = $p < 0\ 05$ between groups)

No differences between HPS and no-HPS were shown in postoperative time on mechanical ventilation (10 4 ± 9.5 *vs* 19 6 ± 18.1 hours) and time on admission in ICU (6 6 ± 0.9 *vs* 8 9 ± 6.7 days). No pulmonary complications were shown in HPS patients, whereas 5 patients without HPS presented complications (pneumonia: n = 4. and pleural effusion: n = 1).

Conclusions: Contrary to No-HPS, in HPS patients Q_S/Q_T decreases breathing 100% O_2 suggesting the presence of functional shunt. In HPS patients who have normal response to 100% O_2, the immediate postoperative evolution was not influenced by low PaO_2 before transplant. Accordingly, we suggest that hypoxemia due to HPS should not be *per se* a contraindication for LTx

A.233 Abrogation of pulmonary dysfunction induced by liver ischaemia-reperfusion: role of circulating xanthine oxidase

A.A Weinbroum[1], Y. Kluger[2], E Karchevski[1], V Rudick[1] [1]*Department of Anesthesiology & CCM and the* [2]*Rabin Division of Trauma, Tel-Aviv, Sourasky Medical Center, Israel*

Background and Goals of Study: We demonstrated the coexistence of lung dysfunction and no flow-reflow conditions in a different organ (Ref). We hypothesized that XO can be responsible for such damage This study aimed at substantiating this contention.

Materials and Methods: Male Wistar rat livers were isolated and perfused with oxygenated Krebs-Henseleit solution (KH), lungs from different rats were ventilated and perfused with KH + 5% bovine serum albumin After 30′ stabilization, livers were continually perfused (Control, n = 8), made globally ischemic (Ischemia, n = 8), or livers retrieved from rats pretreated with XO inhibitor sodium tungstate were also made ischemic (STG, n = 6) for 2 h This was followed by liver + lung 15′-reperfusion phase where the hepatic effluent was connected to the pulmonary circulation Livers were then disconnected and lungs only recirculated with the accumulated KH for another 45′.

Results and Discussion: Peak inspiratory pressure and static compliance decreased (fig 1-A, B) by 40% during lung reperfusion with Ischemia liver effluent, pulmonary vascular resistance also increased. Lungs of the Ischemia group showed a continuous weight gain up to 50% of baseline at 60′ reperfusion (fig. 2) These parameters remained unchanged in the Control and STG groups XO activity in the STG group perfusate was as low as in the Controls but far higher in the Ischemia group This suggests that XO is associated with acute lung injury and tungstate prevented it by preventing the production of XO

Figure 1

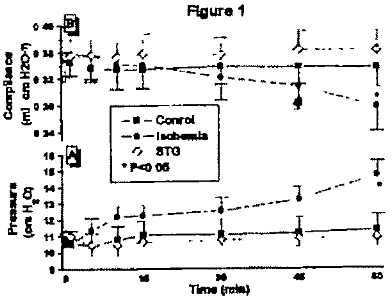

Figure 2

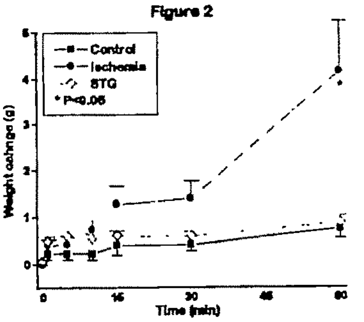

Conclusions: XO induces a direct lung dysfunction when the latter is exposed to compounds released from a different organ undergoing a post-ischemia reperfusion (e.g, liver) The mechanism(s) and location(s) by which XO and possibly oxygen species damage the remote organ functions remain to be further investigated.

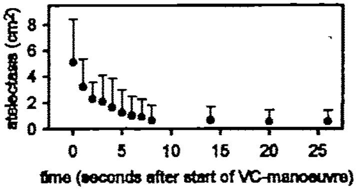
A.234 Re-expansion of atelectasis during general anaesthesia. A study using computed tomography

H U. Rothen, P. Neumann, J E. Berglund, J Valtysson, A. Magnusson, G. Hedenstierna *Departments of Clinical Physiology/Anaesthesiology and Intensive Care/Radiology, University Hospital, Uppsala, Sweden, Anaesthesiology and Intensive Care, University Hospital, Bern, Switzerland*

Background & Goal of Study: During general anaesthesia with mechanical ventilation, gas exchange is regularly impaired. A major cause of this derangement is atelectasis, causing pulmonary shunt [1]. Atelectasis may be re-expanded by a vital capacity (VC-) manoeuvre (i.e. an inflation of the lungs up to VC, kept for 15 seconds) [2]. This results in a decrease of pulmonary shunt and improved oxygenation [3]. However, such a manoeuvre might cause cardiovascular adverse effects. Reducing the time of maximal inflation to a few seconds will improve the margin of safety. The aim of the present study was to analyze the change over time in the amount of atelectasis *during* a VC-manoeuvre.

Material & Methods: A consecutive sample of 12 adults with healthy lungs, scheduled for elective surgery, was included in the study. Intravenous anaesthesia (Fentanyl, Propofol, Pancuronium) with controlled mechanical ventilation was used. For the VC-manoeuvre the lungs were inflated up to an airway pressure (P_{aw}) of 40 cmH$_2$O This pressure was kept for 25 seconds. Atelectasis was estimated by analysis of computed x-ray tomography [2] before and during the VC-manoeuvre

Results & Discussion: (Mean ± SD). The change in the amount of atelectasis over time is shown in the figure. PaO$_2$ increased from 16.9 ± 4.5 before to 21 6 ± 6.4 kPa ($P = 0.03$) after the VC-manoeuvre (FiO$_2$ = 0 4). PaCO$_2$ remained unchanged at 4.7 ± 0.6 kPa (VT = 9 ± 1 ml.kg^{-1}).



Conclusions: In anaesthetized, mechanically ventilated adults with healthy lungs, an inflation of the lungs to a P_{aw} of 40 cmH$_2$O, kept for 6–8 seconds only, may re-expand all previously collapsed lung tissue Thus, the previously proposed time for a VC manoeuvre may be halved in such subjects.

A.235 Vital capacity manoeuvres after cardiopulmonary bypass. Effects on lung function in a pig model

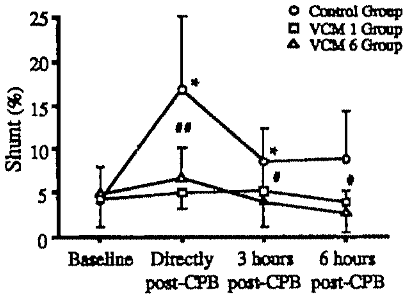
L Magnusson, H Tydén, G. Hedenstierna. *Department of Clinical Physiology and Thoracic Anaesthesiology, Uppsala University Hospital, Sweden*

Background & Goal of Study: Respiratory failure after cardiopulmonary bypass (CPB) remains a major complication after cardiac surgery. In a recent study, using a pig model, we have shown that CPB generates a larger amount of atelectasis (35% of the total lung area) than a control group without CPB (2%) and that PaO$_2$ and intrapulmonary shunt correlated with the amount of atelectasis (1) We tested the benefit of a vital capacity manoeuvre (VCM) performed just before termination of bypass and if there is any advantage of repeating the VCM

Material & Method: 18 pigs received hypothermic CPB and were observed for 6 hours after CPB The VCM was performed in two groups and consisted in inflating the lungs during 15 seconds to 40 cmH$_2$O at the end of the bypass. In one of these groups the VCM was repeated after bypass every hour. The third group served as control Atelectasis was studied by computed tomography and extra vascular lung water (EVLW) by double indicator technique. Analysis for variance (ANOVA) with Bonferroni/Dunn as post hoc test was used.

Results: Intrapulmonary shunt increased after bypass in the Controls but not in the two VCM groups (Figure). Despite a spontaneous but limited improvement intrapulmonary shunt remained significantly lower in the two VCM groups at 3 and 6 hours after CPB. Six hours after CPB the control pigs showed significantly larger atelectasis than in the two other groups The only difference between the two VCM groups was a significantly higher compliance six hours after the end of the bypass in the group with a VCM performed every hour. The amount of EVLW did not increase after CPB in any groups.

Conclusions: In conclusion, a VCM performed at the end of the CPB protect against the increase in intrapulmonary shunt seen in the control group This protective effect of the VCM remains until 6 hours after bypass There is no extra benefit on gas exchange by repeating the VCM.



* $P < 0.05$ compared to baseline; # $P < 0.05$ and ## $P < 0.01$ between the two groups

A.236 Does the prone position improve arterial oxygenation during non-invasive positive inspiratory pressure ventilation?

A Eremenko, D Levikov, V. Egorov *Research Center of Surgery, Moscow, Russia*

Background & Goal of the Study: Beneficial effect of prone position in acute respiratory failure during conventional endotracheal tube ventilation is well known. The aim of the study was to evaluate effect of prone position on arterial oxygenation in the patients under ventilatory support with facial mask.

Materials & Methods: 17 patients with acute respiratory failure (ARF) in the early postoperative period after open heart surgery were studied. The causes of ARF were: ARDS on the stage of recovery, after extubation – 7, dyslectasis of basal segments of the lungs – 8, pneumonia – 2. The ventilatory support was carried out through Respironics facial mask and ventilatory modes employed were· Pressure Support – in 13 and SIMV + Pressure Support – in 4 patients The prone position ventilation was carried out with repeated periods of 30–40 min during prolonged noninvasive mask ventilation (NIMV).

Results of the study are presented in the table (M ± m).

Parameters	PaO$_2$	Qs/Qt	FiO$_2$/PaO$_2$
Units	mm Hg	%	–
Spontaneous	54 ± 15	7 4 ± 0 7	234 ± 30
NIMV	37 ± 42*	4 8 ± 0 6	234 ± 28*
NIMV in PP	101 ± 55*	3 6 ± 0 3*	306 ± 28*

FiO$_2$ = 0.21; PP – prone position, *$p < 0$ 05

Before NIMV, on spontaneous breathing, all patients manifested arterial hypoxemia with diminished values of FiO$_2$/PaO$_2$ and increased Qs/Qt NIMV followed by the significant improvement of arterial oxygenation. and this effect was augmented after turning the patients into the prone position The changes of PaCO$_2$ were not significant.

Conclusions: Prone position is an effective measure leading to further improvement of arterial oxygenation in the patients on the noninvasive mask ventilatory support. It can be recommended as an additional method of respiratory therapy in the patients with postoperative respiratory failure

A.237 Effects of reverse Trendelenburg on compliance and oxygenation indices in obese surgical patients

C. Modesti, L. Sollazzi, V. Perilli, S. Riccardi, R. Ranieri. *Institute of Anesthesiology and Intensive Care, Catholic University, Pol. "A. Gemelli", Rome, Italy*

Background and Goal of Study: Obese patients have several respiratory derangements during surgical procedures and anesthesia. The aim of this study was to evaluate the effects of position changes on respiratory system compliance and gas exchanges in obese patients during bariatric surgery.

Materials and Methods: 20 obese patients BMI > 47.9 ± 7.7 undergoing biliopancreatic diversion were studied. We satisfied the requirements of our institution regarding the use of human subjects in research. Protocol of anesthesia was standard and all patients were mechanically ventilated (Servoventilator 900 C) with· Tidal Volume 6–8 ml/Kg/Total Body Weight aiming to $EtCO_2$ of 30 mmHg, FiO_2 50% Patients were examined at standard times. T_1 after induction of anesthesia, T_2 after laparotomy T_3 after costosternal destructors position, T_4 in reverse Trendelenburg Respiratory system Compliance (C_{rs}) was computed by measuring airways pressures during inspiratory and expiratory holds (3 seconds), artery blood samples were collected for gas analysis at each time. Statistical analysis of data collected was performed employing Student's test ANOVA and regression analysis Data are presented as means ± Standard deviation

Results:

Times	T_1	T_2	T_3	T_4
$DAaO_2$	181 ± 115*	186 + 66	221 ± 68*	196 + 77
$PaO2/FiO_2$	3 4 ± 1 1	2 8 ± 1 2	2 3 ± 0 7	2 9 ± 1
Crs	31 ± 6	33 ± 5 5	33 ± 4 6$^{\$}$	42 ± 8 6$^{\$}$
Peak Paw	34 ± 7 3	31 ± 5 3	32 ± 2 9$^{\#}$	27 ± 3 5$^{\#}$
Plateau Paw	24 ± 5 5	24 ± 4 3	24 ± 3	20 ± 3 3
Mean Paw	9 8 ± 1 5	9 4 ± 2 3	9 2 ± 1 7	8 3 ± 2 8

Conclusions: In our series reverse Trendelenburg position determines a significant improvement of compliance and a decrease in airways pressures Nevertheless this position determines a bit, but non statistically significant improvement of oxygenation indexes It's likely that a change of regional ventilation/perfusion matching could offset the increase of compliance and hence of Functional Residual Capacity as suggested by other authors (1)

A.238 Effects of fentanyl and alfentanil on breathing pattern during halogenated anaesthesia

J Canet[1], P. Vila[1], J. Giner[2], R G Guasch[1], J. Sanchis[2], F Vidal[1] [1]*Dept of Anaesthesiology, Hospital Germans Trias i Pujol, Badalona,* [2]*Dept of Pneumology, Hospital Sant Pau, Barcelona, Spain*

Background & Goal of Study: Halogenated anaesthetics and opiates have different depressant effects on ventilatory control[(1)]. We compared the breathing pattern during halothane (HAL) or isoflurane (ISO) anaesthesia at 1 2 MAC and after the addition of fentanyl (FEN) or alfentanil (ALF)

Material & Methods: After institutional approval and informed consent, 40 patients undergoing surgery were enrolled Subjects received 1.2 MAC of HAL or ISO in O_2. When breathing was stabilized, flow and end-tidal CO_2 pressure ($PETCO_2$) were recorded. Afterwards, a single equipotent dose of FEN (1 $\mu g.kg^{-1}$) or ALF (6 $\mu g\ kg^{-1}$) was given and measurements were repeated again five minutes later. Breathing pattern was analyzed in terms of inspiratory time (TI), inspiratory to total time ratio (TI/TTOT), respiratory rate (RR), tidal volume (VT), minute ventilation (VE) and mean inspiratory flow rate (VT/TI) Statistical analysis was performed by MANOVA with significance considered at $p < 0.05$

Results & Discussion: ISO depresses ventilation more than HAL. When opiates were added, RR and VE were thus markedly reduced and $PETCO_2$ increased, despite a moderate increase in VT. FEN reduced VE more than ALF, however, VT/TI remained the same.

	Halogenated		Halogenated + opiate	
	HAL	ISO	FEN	ALF
TI (s)	0 98 ± 0 17	1.01 ± 0 19	1 42 ± 0 22	1 31 ± 0 27
TI/TTOT	0.44 ± 0 03	0 43 ± 0 04	0 23 ± 0 10	0 30 ± 0 07*
RR (c/min)	28 1 ± 5 2	26 4 ± 5 7	10 3 ± 5 4	14 8 ± 5 5*
VT (L)	0 26 ± 0 06	0.21 ± 0 03^{+}	0 31 ± 0 13	0 29 ± 0 08
VE (L/min)	7 30 ± 2 10	5 30 ± 1.07^{+}	2 97 ± 1 60	3 98 ± 1 03*
VT/TI (L/s)	0 28 ± 0 08	0 22 ± 0 04^{+}	0 25 ± 0 10	0 24 ± 0 04
$P_{ET}CO2$ (mmHg)	48 0 ± 4 4	52 2 ± 6 6	62 5 ± 8 1	54 7 ± 6 6*

Conclusions: Opiates produce marked changes in breathing pattern. Their addition to halogenated agents affects mainly the processes that regulate timing through a delay in the inspiratory switch-off mechanism and to a greater extent through prolongation of expiratory time, while driving seems to hold steady due at least in part to increased $PETCO_2$

A.239 Comparative effects of halothane and isoflurane on ventilation

J Canet, P. Vila, J. Sanchis, J Giner. *Servei d'Anestesiologia, Hospital Universitari Germans Trias i Pujol, Badalona, Departament de Neumologia, Hospital de Sant Pau, Barcelona, Spain*

Background & Goal of Study: Halogenated anaesthetics have ventilatory depressant effects due to their effects on central control of breathing Each may have specific effects through actions either on timing or driving The present study aimed to compare the effects of halothane (HAL) and isoflurane (ISO) on breathing pattern, end-tidal CO_2 pressure ($PETCO_2$) and inspiratory occlusion pressure at 100 ms (P0 1)

Material & Methods: Seventy-four patients were enrolled in the study after institutional and individual consent forms were signed After anaesthetic induction and orotracheal intubation with thiopental and succynicholine Randomly the patients received 1 2 CAM of HAL (N = 37) or ISO (N = 37) in O_2 When patients breathed spontaneously, a continuous recording of ventilation and $PETCO_2$ were performed for 2 min Three manoeuvers of inspiratory occlusion were performed in order to P0 1 Inspiratory time (TI), TI to total time ratio (TI/Ttot), respiratory rate (RR), tidal volume (VT), minute ventilation (VE) and mean inspiratory flow rate (VT/TI) were calculated breath by breath P0 1 was averaged from the 3 manoeuvers Statistical analysis was performed with a *t* test

Results: The table shows the mean values (SD) for all parameters for each group

	HAL (N = 37)	ISO (N = 37)	*P*
TI (s)	0 96 (0 15)	1 02 (0 17)	NS
TI/Ttot	0 45 (0 03)	0 42 (0 04)	0 012
RR (c/min)	28 5 (4 8)	25 8 (5 8)	0 036
VT (L)	0 26 (0 05)	0 22 (0 04)	0 0001
VE (L/min)	7 28 (1 72)	5 54 (1 15)	0 0001
VT/TI (L/s)	0 28 (0 08)	0 23 (0 04)	0 0001
$PETCO_2$ (mmHg)	47 8 (4 6)	51 4 (6 7)	0 008
PO 1 (cmH_2O)	2 93 (0 98)	1.75 (0 78)	0 0001

Conclusions: ISO is more ventilatory depressant than HAL at the same MAC This difference is due to specific effects on timing because ISO produces a delay in the inspiratory switch on and on driving output because ISO reduces it Together, these effects produce a greater reduction in minute ventilation and hypoventilation

Supported by Fondo de Investigaciones Sanitarias (FIS 94/617) Spain

A.240 Acute respiratory failure in patients after surgical thoracic oesophagectomy

E Zavala, F.X. González, L Sabater, R. Rull, M.A López-Boado,
N. Fábregas, G. Martinez, A Alcón. *Surgical ICU, Hospital Clinic, University of Barcelona, Spain*

Background and Goal of Study: Respiratory complications are the main cause of morbidity after oesophagectomy. The mechanisms of lung injury following surgical oesophagectomy are unclear The aim of this study is to describe the onset of acute respiratory distress syndrome (ARDS) after transthoracic oesophagectomy in patients with oesophageal malignant tumors, and evaluate possible risk factors associated with this complication

Material & Methods: We have prospectively studied the respiratory complications in 28 patients who underwent surgical transthoracic oesophagectomy between January 1995 and June 1997 Several risk factors have been examined in order to evaluate its association with the development of ARDS A total of 60 parameters were analyzed in each patient 35 preoperative (including underlying disease, pulmonary function tests, nutritional state, risk index, etc), 10 variables referred to the surgical intervention and the tumor characteristics (surgical approach, tumor localization and characteristics, tumor stage, surgical duration, need of transfusion, etc), and 15 variables referred to the postoperative period (APACHE II score and TISS at admission in the ICU, pulmonary complications, reintubation, mechanical ventilation duration, SICU evolution, etc)

Results and Discussion: Fourteen patients (50%) presented some kind of pulmonary complication during the postoperative period 7 pneumonia or atelectasis, 2 tracheobronchitis, and 5 ARDS (18%) This latter group of patients with ARDS (mean age of 59.2 ± 10 7 years, APACHE II score of 18 6 ± 5 5, and TISS of 45.6 ± 5 5) had been extubated during the first 24 hours; however, on the third postoperative day developed hypoxemia and diffuse pulmonary infiltrates (Murray score >2.5) requiring reintubation and mechanical ventilation. Significant statistical differences ($p < 0\ 05$) between patients with and without ARDS were observed in preoperative FEV_1/FVC (62 ± 19 vs 75 ± 6), tumor location at the middle third of the oesophagus (100% vs 34%, p = 0 02) and mortality (60% vs 9%, p = 0 006)

Conclusions: ARDS is a frequent complication (18%) after surgical transthoracic treatment of oesophageal cancer, associated with high mortality (60%) A low preoperative FEV_1/FVC and location of the tumor at the middle third of the oesophagus have been found to be associated with

ARDS This latter factor may condition a longer lung manipulation during transthoracic oesophagectomy and en-block lymphadenectomy Postoperative conditions that allow a quick extubation on the postoperative period do not exclude the probability to develop ARDS.

A.241 Pulmonary gas exchange during hyperthermia

M. Deja[1], T Kemer[1], O. Ahlers[1], J. Loffel[2], H. Riess[2], P. Wust[3], D Pappert[1], H Gerlach[1]. [1]*Abt. f. Anästhesiologie & operat. Intensivmedizin;* [2]*Abteilung für Hämatologie/Onkologie;* [3]*Strahlenklinik und-poliklinik, Virchow-Charité, Humboldt-Universität, 13344 Berlin, Germany*

Background: The efficacy and tolerance regarding pulmonary gas exchange of systemic Cancer Multistep Therapy (sCMT) by Ardenne was tested in patients with colorectal carcinoma This therapy consists of a whole body hyperthermia at a temperature of 42°C with additional chemotherapy, hyperoxaemia, and hyperglycaemia

Methods: During 11 sCMT treatments in six patients (aged from 37–54 years) during TIVA and inhalation of O_2-air mixture, pulmonary gas exchange and haemodynamics were examined at 4 time points: 1. at 37°C, before the warming-up, 2. in the warming-up phase at 40°C, 3 at 42°C; 4. in the cooling-phase at 39°C) The patients were ventilated in the volume controlled mode (PEEP 5–10 cmH_2O, respiratory rate 10–16/min, I E = 1.2, FiO_2 as to achieve a $paO_2 > 250$ mmHg) and metabolic monitoring was performed (Puritan-Bennett® 7200 AE and 7250) The haemodynamic monitoring consisted of a Swan-Ganz catheter (Baxter Explorer®), a lung water catheter positioned in the A femoralis (Pulsion COLD Z-021® and an arterial line (A. radialis). The patient was warmed with a water-filtered infrared-A irradiation (IRATHERM 2000®). Statistical test Wilcoxon rank sum test. Significance was defined by $p < 0.05$.

Results: The oxygen consumption increased significantly, as measured with indirect calorimetry using Fick's equation and measurement of the respiratory gas fraction. To achieve a normal $paCO_2$ (35–40 mmHg), minute ventilation (MV) was significantly increased with a maximum at 42°C (MV at 37°C: 7 4 l/min, at 42°C: 12.3 l/min [median], $p < 0.0001$) Concurrently oxygen delivery and cardiac output increased significantly ($p < 0.0032$ and $p < 0.001$, respectively). In contrast, arterial-venous oxygen difference remained constant. Alveolo-arterial oxygen partial pressure difference and intrapulmonary right-to-left shunt were significantly increased at 42°C ($p < 0.05$ and $p < 0.03$, respectively) and fell again during the cooling period, so that a comparison with the measurements at 37°C did not differ significantly The compliance of the lungs and the dead space remained unchanged Although the pulmonary vascular resistance fell moderately, mean pulmonary arterial pressure increased significantly parallel to the rise of CO Extravascular lung water remained within normal range (approx. 4 ml/kg).

Conclusions: Whole body hyperthermia during general anaesthesia and controlled respiration induced significant changes regarding pulmonary gas exchange. These changes were, however, moderate and were reversible during the cooling period Hence, for cardiac and pulmonary healthy patients no deterioration in pulmonary gas exchange has to be expected

A.243 Pressure-controlled ventilation *vs* volume-controlled ventilation during general anaesthesia with peroperative respiratory system dynamic compliance changes

Nathalie Vialles, Xavier Capdevila, Edith André, Philippe Biboulet, Christian Plasse, Françoise d'Athis *Department of Anesthesiology Lapeyronie University Hospital 34292 Montpellier, France*

Background and Goal of Study: In intensive care unit, PCV is widely used by physicians. This ventilatory alternative to VCV is claimed to improve alveolar ventilation and to decrease peak airway pressure during respiratory system compliance decreases, thereby limiting lung damage. Therefore we prospectively studied the respiratory mechanic parameters when comparing PCV to VCV during general anaesthesia with respiratory system dynamic compliance changes.

Patients and Method: After institutional approval, 23 ASA 1 or 2 patients scheduled for total hip replacement under general anaesthesia (thiopental, sufentanil, isoflurane in $50\%O_2/50\%N_2O$) were enrolled. Each patient was randomly assigned to receive successively PCV and VCV (Excel 7900, Ohmeda corp, USA) in dorsal decubitus position then in lateral decubitus position. Each patient was his own referee. The ventilatory targets: tidal volume (Vt) at 8 ml/kg, respiratory rate (RR) at 12 b/min, TI/Te ratio at 1/1.5 and end expiratory pressure at 0 cm H2O were identical between both ventilatory modes and both positions. After 10 minutes of ventilatory stability in each mode and each position, other ventilatory parameters were measured (Capnomac Ultima, Datex corp, Finland) at the proximal port of the tracheal tube: peak airway pressure (P peak, cmH2o), airway pressure level at end-inspiration (Pplat, cmH2O), total respiratory system compliance (Crs, ml/cmH2O), minute ventilation (VE, L/min) Pet Co2 (cmH2O), Spo2, mean arterial pressure (map) and heart rate (hr) were also continuously monitored Mann and Withney tests were used.

Results: Vt, RR, Ti/Te, SpO2, map and hr values were similar in both ventilatory modes and positions. Other peroperative respiratory variables are reported in the table

	VCV		PCV	
	dorsal dec	lateral dec	dorsal dec	lateral dec
Crs	51 0 ± 11 2	40 0 ± 8 9°	51 9 ± 10 7	41 7 ± 8 4°
Ppeak	15 1 ± 3 3	17 ± 3 5°	13 4 ± 2 7*	14.7 ± 2 5*°
Pplat	14 3 ± 3 0	16 0 ± 2 9°	13 3 ± 2 *	14 6 ± 2 5*°
VE	5 5 ± 1 1	5 5 ± 1 0	5 5 ± 1 0	5 5 ± 1 0
PetCo2	32 2 ± 1 9	32 2 ± 2 3	32 1 ± 2 1	32 ± 52 6

*p < 0 05 versus VCV, °p < 0 05 versus dorsal decubitus

Discussion and Conclusion: During general anaesthesia with peroperative respiratory system compliance decreases, PCV allows a constant targeted Vt with lesser Ppeak and Pplat than VCV. These results may be due to the decelerated inspiratory flow and the improved alveolar gaz distribution. Further studies are necessary to define the advantages of PCV in routine anesthetic procedures and in patients dependant of hemodynamic and respiratory stability.

A.244 Pressure-controlled ventilation with a laryngeal mask airway during general anaesthesia

Edith André, Xavier Capdevila, Nathalie Vialles, Philippe Biboulet, Christian Plasse, Françoise d'Athis *Department of Anesthesiology, Lapeyronie University Hospital, 34295 Montpellier, France*

Background and Goal of Study: When using a LMA with positive pressure ventilation, air leaks are directly proportional to the airway pressure (1). In an other hand, PCV is usually used with tracheal tubes without inflatable cuff in children to improve the targeted tidal volume (Vt), thereby limiting gastric insufflation or neck leaks Therefore we prospectively studied the respiratory mechanic parameters and air leaks when comparing PVC to volume controlled ventilation (VCV) during general anaesthesia using a LMA.

Patients and Methods: After institutional approval, 28 ASA 1 patients scheduled for minor orthopedic surgery procedures under general anaesthesia (propofol, fentanyl, 50% O2 50% N2O) were enrolled Each patient was randomly assigned to receive successively PCV and VCV (Excel 7900, Ohmeda corp, USA) with the LMA, in dorsal decubitus position. Each patient was his own referee. The ventilatory targets: inspiratory tidal volume (Vti) at 8 ml/kg, a respiratory rate (RR) at 12 b/min, a Ti/Te ratio at 1/1.5 and an end expiratory pressure at 0 cm H2O were identical between both ventilatory modes. After 10 minutes of ventilatory stability in each mode, respiratory parameters were measured (Capnomac Ultima, Datex corp, Finland) at the proximal port of the tracheal tube: total respiratory system compliance (Crs), expiratory tidal volume (Vte), air leaks around the LMA, minute ventilation (VE), peak airway pressure (Ppeak). PetCO2, SpO2, mean arterial pressure and cardiac frequency were continuously monitored. Mann and Withney tests were used for statistical comparisons.

Results: Vti, RR, Ti/Te, SpO2 and hemodynamic variables values were similar in both ventilatory modes. Other peroperative respiratory variables are reported in the table

	Crs ml/cmH2O	Ppeak cm/H2O	Vte ml	Leaks ml	VE l/min	PetCO2 cm/H2O
VCV	54 ± 9	15 ± 5	508 ± 78	60 ± 36	6 ± 1	32 ± 3
PCV	54 ± 10	12 ± 3*	529 ± 14*	38 ± 20*	6.4 ± 1*	33 ± 3

*p < 0 05 versus VCV

Discussion and Conclusion: In comparison to VCV, PCV during general anaesthesia produces lower peack airway pressure for the same targeted Vti and as such decreases the leaks around the LMA thereby improving Vte and VE values. Additional studies are necessary to define the benefits of PPV in routine anesthetic procedures.

A.245 Influence of tracheal stenosis on high frequency jet ventilation: a model study

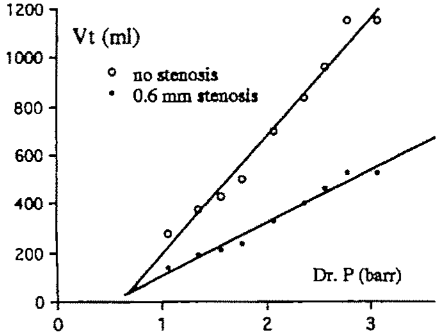
M. Dejonckheere, D. Verbessem, A d'Hollander. *Dept of Anesthesiology, Hopital Erasme (ULB), Brussels, Belgium*

Aim of the Study: High Frequency Jet Ventilation (HFJV) is commonly used during endoscopic laser resection of tracheal stenosis (1). We measured lung volumes and airway pressures at variable HFJV settings using a lung model with tracheal stenosis of different diameters.

Material and Methods: A lung model (Demonstration Lung LS 800 Dragerwerk) was ventilated using HFJV (MK 800, Acutronic Medical System, Switzerland) through a triple-lumen tracheal tube (Hi-Lo) at increasing driving pressure (Dr P), frequency (f) and I/E ratio. 2 cm thick diaphragms were inserted distally to the tracheal tube to simulate stenoses of 9, 8, 7 and 6 mm of diameter. Magnetometer coils were attached on each end of the bellows to assess Tidal Volume (Vt) and Increase in Functional Residual Capacity (FRC). Airway pressures were measured with a pressure transducer below the tracheal stenosis.

Results and Discussion:

Results and discussion:



Without stenosis, Vt varied linearly with increases in Dr P or I/E. Vt decreased when f increased. High Dr P, frequency or I/E settings resulted in PEEP and pulmonary hyperinflation

Narrowing the tracheal stenosis to 6 mm decreased Vt at any HFJV setting ($p < 0.05$), but had no significant effect on PEEP or FRC.

Conclusion: Our study suggests that, during HFJV, tracheal stenoses mainly produce hypoventilation when the injector is proximal to the tracheal narrowing Adjusting the ventilator to an adequate Vt might increase the risk of pulmonary hyperinflation

A.246 High-frequency ventilation techniques improve oxygenation in patients with impaired pulmonary function

G Ihra, A. Kepka, C. Schabernig, P Kraincuk, A. Aloy. *Dept. of Anaesthesiology and Intensive Care Medicine, Univ of Vienna, Austria*

Background and Goal of Study: High-frequency (HF) ventilation techniques have been introduced as alternative ventilatory modalities during laryngeal and pulmonary surgery, in patients with bronchopleural fistulae, or to improve impaired oxygenation (1) To study the proposed beneficial effects of HF ventilation on oxygenation we treated ICU patients with either HF oscillatory ventilation (HFO) or HF jet-ventilation (HFJV)

Materials and Methods: 36 patients of a surgical intensive care unit (25 male/11 female, 51 ± 18 yrs) were ventilated with a pneumatic HFO ventilator (VDR4, Percussionaire Corp., Idaho, U.S A) or an electronic prototype superimposed-HFJV respirator (Alexander I, Fa. Reiner, Austria) Superimposed HFJV was characterized by simultaneous application of low-frequency and high-frequency jet-streams for adequate CO_2 elimination through small-bore cannulas of a special jet-adapter connected to the conventional endotracheal tube. Indications for HF ventilation were pulmonary insufficiency (20), atelectases (13), and bronchopleural fistula (3) HF rates of HFJV and HFO were set between 500 and 700/min, the conventional respiratory rates ranged from 10–18/min. Oxygenation index (OI, paO_2/FiO_2) and PIF (PEEP × I:E × FiO_2) were evaluated before and after 24 hours of continuous HF ventilation. Data (mean ± SD) were statistically analyzed using the paired *t*-test ($p < 0.01$).

Results: HFV resulted in improved oxygenation in 27 of 36 patients (75%). OI increased in 21 responders to HFJV from 131 ± 71 to 181 ± 87, PIF could be reduced in 12 of these patients Likewise, OI increased in 7 responders to HFO (88%) from 121 ± 37 to 196 ± 84, PIF could be reduced in 6 of these patients CO_2 levels (50 ± 20 *vs* 49 ± 16 mmHg) did not increase during 24 h of HFV No ventilator associated complications were observed

Conclusion: Although the mechanisms of HFV have not been clarified in the past, superimposed HFJV and HFO are safe and effective to improve impaired oxygenation. These HFV techniques also facilitate adequate ventilation avoiding an increase in arterial CO_2 levels. However, not all patients may respond to HFV and will need additional therapeutic interventions to improve pulmonary function.

A.247 Alveolar pressure measurement in patients with acute lung injury (ALI)

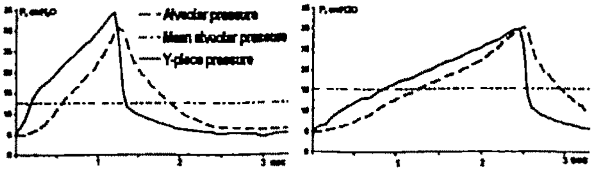
Soren Söndergaard, Sigurbergur Kárason, Stefan Lundin, Ola Stenqvist. *Department of Anesthesia and Intensive Care Sahlgrenska University Hospital, Goteborg, Sweden*

Background and Goal of Study: To avoid barotrauma it is important to monitor alveolar pressure So far alveolar pressure has been estimated from pressure measured proximal to the endotracheal tube. This pressure is distorted by tube resistance We have developed a method for continuous measurement of alveolar and y-piece pressure together with ventilatory volumes and flows from a side stream spirometer using a Datex AS/3 monitor

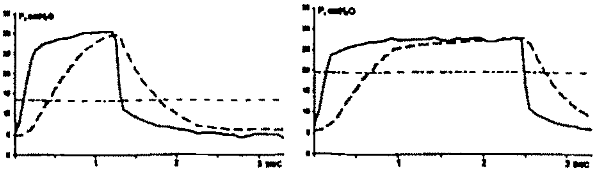
Materials and Methods: In seven ALI patients, a thin pressure line was introduced through an airtight cuff at the y-piece and placed in the trachea Tracheal pressure was plotted versus tidal volume Assuming equal inspiratory and expiratory resistances the level of the alveolar pressure was determined from the ratio of inspiratory and expiratory flow at the same ventilation volume Alveolar and y-piece airway pressures were plotted versus time

Results & Discussion: During pressure control ventilation and respiratory freq 16, the time delay before alveolar pressure reached a plateau was app. 1 sec and independent of I:E ratio. During volume control ventilation the delay was very short but pressure rises slowly, continuously throughout inspiration. Mean alveolar pressure increases stepwise when I:E ratio was prolonged from 1:2 to 2:1 during pressure control despite no intrinsic PEEP occurring. During volume controlled ventilation mean alveolar pressure was low at I:E ratio 1:2 and increased slightly at I:E ratio 2:1. Overall mean alveolar pressure was 25–30% lower during I:E ratio 1:1 and 2:1 with volume compared to pressure control ventilation

Volume controlled ventilation



Pressure controlled ventilation



I:E ratio1:2 **I:E ratio 2:1**

Conclusions: Pressure control inverse I:E ratio ventilation produce higher mean alveolar pressure as alveolar plateau pressure level is reached faster than during volume control despite the same tidal volume, peak alveolar and end expiratory alveolar pressure The y-piece pressure overestimates inspiratory pressure and underestimates expiratory pressure profile. Mean y-piece pressure was however close to the mean alveolar pressure irrespective of ventilatory mode

A.248 Comparison of expiratory washout and optimized conventional mechanical ventilation during permissive hypercapnia

J. Richecoeur, S. Vieira, Q Lu, L Puybasset, P. Kalfon, P. Conat, J J. Rouby. *Department of Anesthesiology, La Pitié-Salpêtriere, Paris, France*

Background and Goal of the Study: EWO can be used as an adjunct to mechanical ventilation to reduce $PaCO_2$. Optimizing conventional ventilation by increasing respiratory rate to the limit of auto-PEEP and reducing the instrumental dead space (by removing the connecting tube between the endotracheal tube and the Y piece) could be an attractive alternative The aim of this study was to compare EWO, OCMV and the combination of both modes (OCMV + EWO) during permissive hypercapnia (PH) in patients with ARDS.

Patients and Methods: After local ethic committee approval and informed consent, 6 sedated and paralyzed patients (mean age = 45 ± 15 yrs) with severe ARDS (LISS = 3.2 ± 0.5 and PaO_2/FIO_2 at admission = 137 ± 50 mmHg) were studied $PaCO_2$ and pH values were 84 ± 24 mmHg and 7.21 ± 0.12 respectively during PH with the following ventilatory settings respiratory rate 18 b/mn; tidal volume adjusted in order to obtain an inspiratory plateau pressure (Pplat) equal to the upper distending pressure minus 2 cmH_2O; PEP equal to the lower inflection point plus 2 cmH_2O. The 3 conditions were performed in a random order and preceded by a return to the control condition (PH). Pplat was kept constant by adjustment of the external PEEP in all conditions. Values are presented as mean ± SD.

Results: The changes in $PaCO_2$ and pH induced by OCMV and EWO were similar (−24 ± 10 vs −23 ± 10 mmHg and +0 15 ± 0 01 vs +0.15 ± 0.01, NS). Both techniques had additive effects and their combination induced a reduction in $PaCO_2$ of −40 ± 17 mmHg and an increase in pH of +0.26 ± 0.06. In order to maintain Pplat constant, external PEEP had to be reduced by 5.3 ± 2 1 cmH_2O during EWO and by 7.3 ± 1.3 cmH_2O during the combination of OCMV ± EWO No change in external PEEP was necessary during OCMV alone. PaO_2 and cardiac output remained constant in all the conditions tested.

Conclusion: The conventional ventilation optimized by increasing respiratory rate and reducing the instrumental dead space is as efficient as expiratory washout for CO_2 removal in patients with ARDS and permissive hypercapnia The combination of both techniques have additive effects.

A.249 Effectiveness of total and partial expiratory washout in permissive hypercapnia

J. Richecoeur, Q Lu, S Vieira, L Puybasset, P Kalfon, P. Coriat, J J. Rouby *Department of Anesthesiology, La Pitié-Salpêtrière, Paris, France*

Background and Goal of the Study: The efficacy of EWO delivered during the entire expiratory phase has been recently demonstrated[1] However, one of the drawback of the technique is to generate intrinsic PEEP and to increase inspiratory plateau airway pressure, thereby increasing the risk of barotrauma. We hypothesized that delivering EWO only during the late phase of the expiration might reduce this side effect

Patients and Methods: After local ethic committee approval and informed consent, 7 sedated and paralyzed patients (mean age = 45 ± 17 yrs) with severe ARDS (LISS = 3 2 ± 0 5, PaO_2/FIO_2 at admission = 126 ± 55 mm Hg) were studied $PaCO_2$ and pH values were 97 ± 35 mmHg and 7 16 ± 0 12 respectively with the following ventilatory settings· respiratory rate 18 b/mn; tidal volume adjusted in order to obtain a plateau pressure equal to the upper distention point minus 2 cmH_2O; PEEP equal to the lower inflection point plus 2 cmH_2O EWO was limited to the last second of the expiratory phase in partial EWO and delivered during the entire expiration in total EWO Total and partial EWO were studied in cross over, each preceded by a return to the control condition. Plateau pressure was kept constant by adjusting external PEEP in all conditions tested. Values are presented as mean ± SD

Results: Total and partial EWO induced similar decreases in $PaCO_2$ [−31 ± 24 mmHg (−29%) vs −33 ± 21 mmHg (−34%)] and increases in pH [+0.16 ± 0 01 vs +0 18 ± 0.01; NS]. As compared to the control condition, PaO_2 was significantly lower during partial EWO [−50 ± 50 mmHg (−26%)]. To maintain inspiratory plateau pressure constant, external PEEP had to be reduced similarly in both modes [−5.7 ± 2 1 (46%) vs −5.7 ± 1.6 cmH_2O (47%)]. However the minimal airway pressure was lower during partial EWO than during total EWO [−51% vs −33%, $p < 0.01$].

Conclusion: The implementation of EWO during the late phase of the expiration showed no benefit in terms of CO_2 removal and intrinsic PEEP reduction. It may even be detrimental on PaO_2 because of alveolar derecruitement occurring during the early phase of the expiration.

A.250 Effect of pipecuronium in isolated human bronchi

L. Zappi, S. Ping-Fang, S. Nicosia, F Nicosia, K Rehder *National Institute for Cancer Research, Genoa, Italy*

Introduction: Airway caliber is determined by the balance of pre- and postjunctional muscarinic receptor activity. Stimulation of postjunctional muscarinic receptors induces bronchoconstriction By contrast stimulation of prejunctional muscarinic receptors inhibits acetylcholine (Ach) release, reducing airway smooth muscle contraction Neuromuscular blockers can interact with pre-and postjunctional muscarinic receptors (1) The current experiments examined the effects of pipecuronium on pre- and postjunctional muscarinic receptors in isolated human bronchi

Methods: Isolated human bronchial rings (3-mm ID) were suspended in organ baths filled with physiological salt solution (PSS) at 37°C and aerated with 95% O_2 and 5% CO_2 They were stretched until the contractile response to electric field stimulation (EFS) was maximal and constant (optimal length); they were kept at this length throughout the study Four bronchial rings from each of six patients were first incubated with 10^{-6} M Tetrodotoxin (TTX) and then contracted with Ach (cumulative half-log increments, 10^{-9} to 10^{-2} M). Thereafter they were washed with PSS containing TTX, incubated with pipecuronium 10^{-7} M (n = 6), 10^{-6} M (n = 6), 10^{-5} M (n = 6) and again contracted with Ach. Four bronchial rings from each of the same six patients were incubated with either 10^{-7} M, 10^{-6}M or 10^{-5} M pipecuronium; pilocarpine (10^{-9} to 10^{-4} M) was then added The fourth ring from each patient served as a control All four rings were contracted every 3 minutes for 30 sec. by EFS (25 Hz, 25 v, 0.5 ms), before and after the addition of each concentration of pilocarpine

Results: Pipecuronium (10^{-7}, 10^{-6}, 10^{-5}M) did not alter the contractile responses to Ach, suggesting no inhibitory postjunctional M_3-receptor effect. By contrast, pipecuronium (10^{-6} to 10^{-5} M) shifted the concentration-response curve of pilocarpine significantly ($P < 0.05$) to the right, suggesting an inhibitory effect on prejunctional M_2-receptors. Pipecuronium 10^{-5} M but not 10^{-6} M and 10^{-7} M reduced significantly the resting force, but the right shift of the pilocarpine-concentration-response curve was independent of the increase in the resting force

Conclusions: In isolated human bronchial rings pipecuronium is a M_2- but not M_3- muscarinic receptor antagonist. Pipecuronium could therefore increase reflex-induced bronchoconstriction

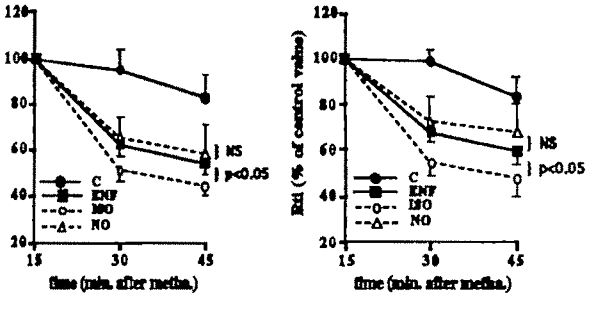
A.251 Comparative effects of nitric oxide, enflurane and isoflurane on respiratory resistance with methacholine-induced bronchoconstriction

J Y Sim, K S Hwang, I.C. Choi, P H Park. *Dept. of Anesthesiology, College of Medicine, University of Ulsan, Asan Medical Center, Seoul, Korea*

Background and Goal of Study: The aim of this study was to compare the effects of NO, enflurane and isoflurane on respiratory resistance using flow-interruption technique[1].

Materials and Methods: Twenty eight cats were divided into 4 groups according to the agents administered, C (control), NO (20 ppm of NO), ENF (1 MAC of enflurane) and ISO (1 MAC of isoflurane) groups. Tracheal pressure was measured at 2–3 cm beyond the distal end of the tube After measuring the baseline value, methacholine (25 μg/kg/min) was infused to induce bronchoconstriction which was continued throughout the experiment Agents were administered for each group 15 min after methacholine infusion (control value) via low pressure inlet of the ventilator Measurements were made every 15 min. IMV was applied with Servo 900C® ventilator. Inspiratory flow rate and tidal volume were fixed throughout the experiment for each subject Pressure, volume and flow were monitored with Bicore CP100® pulmonary monitor The data were transferred to a PC and analyzed by a processing software. Total respiratory (Rrs), airway (Raw) and tissue (Rti) resistances were calculated[1]. One way ANOVA with Student-Newman-Keuls *post hoc* test was used for statistical analysis.

Results and Discussion: The figures show the changes of Raw and Rti.



Conclusion: For NO, ENF and ISO, both Raw and Rti were reduced ISO was more potent than ENF in contrary to the previous report[2]. NO was as effective as ENF in reversing bronchoconstriction.

A.252 Inhaled nitric oxide improves ventilation/perfusion relationship after anoxic ischaemia and reperfusion in isolated rabbit lungs

G. Hermle[1], H. Schutte[2], W. Seeger[2], K. Geiger[1]. *Anaesth. Department, [1]University of Freiburg, Med Dept., [2]University of Giessen Hugstetter Str. 55, D 79106 Freiburg, Germany*

Background and Goal of Study: Ischaemia and reperfusion cause damage to the lung. The tissue injury is associated with pulmonary hypertension and impaired endothelial permeability. It is assumed that a decreased production or neutralization of endogenous nitric oxide (NO) contributes to the lung injury. Inhalation of NO has been shown to attenuate the reperfusion injury. This study was designed to examine the influence of exogenous

NO on ventilation/perfusion-relationship (V_A/Q) after anoxic ischaemia and reperfusion in isolated, buffer perfused rabbit lungs

Material and Methods: Two hours of anoxic ischaemia (95% N_2, 5% CO_2) were followed by 90 minutes of normoxic reperfusion (21% O_2, 5% CO_2) (n = 9) NO was administered at the start of reperfusion (n = 4) Pulmonary artery pressure (PAP), double occlusion pressure, and left atrial pressure as well as lung weight were measured V_A/Q-relationship was determined before anoxic ischaemia and after 15, 30, 60, and 90 minutes of reperfusion using the multiple inert gas elimination technique (MIGET) Inhaled NO was measured by chemiluminescence

Results: Anoxic ischaemia and reperfusion resulted in a severe V_A/Q mismatch The lung weight gain limited the reperfusion period to 30 min Shunt flow increased almost 10 fold. The log dispersions of perfusion and ventilation were broadened The log mean of perfusion was shifted to the left whereas the log mean of ventilation showed a movement towards high V_A/Q-areas Inhalation of NO attenuated lung weight gain and PAP, and prolonged the reperfusion period to 90 min The V_A/Q-relationship was improved. Shunt flow was reduced The V_A/Q-relationships of ventilation and perfusion showed a unimodal and narrow log dispersion and a matched log mean within normal limits.

Table V_A/Q-ratio of perfusion after anoxic ischaemia

	NO [ppm]	Pre ischaemia	Time [min]		
			135′	150′	210′
Shunt	0	1 8 ± 0 5	17 2 ± 6 3#	31 5 ± 7 2#	
	10	2 1 ± 0 4	3 5 ± 0 9	4 9 ± 0 6	6 0 ± 2 2
[%]	control	2 0 ± 0 5	2 1 ± 0 2	1 7 ± 0 5	2 2 ± 0 4
Low	0	0 0 ± 0 0	19 3 ± 7 1#	7 8 ± 2 8	
V/Q	10	0 5 ± 0 4	2 6 ± 1 7	2 8 ± 1 4	2 0 ± 1 4
[%]	control	0 0 ± 0 0	0 0 ± 0 0	0 0 ± 0 0	0 0 ± 0.0
Normal	0	98 4 ± 0 5	62 7 ± 7 5#	59 7 ± 6 8#	
V/Q	10	97 4 ± 0 2	94.0 ± 1 7	92 5 ± 1 9	92 0 ± 3 4
[%]	control	98 0 ± 0 5	97 9 ± 0 2	98 3 ± 0 5	97 8 ± 0 4

Values are means ± SEM, # = $p < 0\ 05$ vs control and 10 ppm NO

Conclusion: Inhaled nitric oxide is a useful agent to reduce reperfusion injury and to prevent the V_A/Q-mismatch after a prolonged period of anoxic ischaemia

A.253 Effects of inhaled nitric oxide, L-NAME and the association of both in an experimental model of one-lung ventilation

A López, I Rovira, G Fita, E Carrero, S. Herrero *Dept d'Anestesiologia, Hospital Clinic, Fac de Medicina, Universitat de Barcelona, Spain*

Background and Goal of Study: During one lung ventilation (OLV) inhaled nitric oxide (NO) increases pulmonary blood flow to the ventilated lung and improves gas exchange, although this effect does not seem to be dose- dependent (1) Intravenous N^G-Nitro-L-Arginine (L-NAME), a nitric oxide synthase inhibitor, by increasing hypoxic pulmonary vasoconstriction (HPV) reduces right to left shunt in experimental models (2) We compared the effects of inhaled NO, i v. L-NAME, and the association of both upon partial arterial oxygen pressure (PaO_2) and pulmonary blood flow in an experimental model of OLV.

Material and Methods: Seven anaesthetized sheep were studied under left lung ventilation. Left pulmonary blood flow (LPBF) was measured by an electromagnetic probe attached to the left pulmonary artery Measurements of systemic and pulmonary haemodynamics, and LPBF were performed at baseline conditions, after 10 minutes of NO inhalation (40 ppm), after a second basaline period without NO, 30 minutes after 30 mg.Kg^{-1} of i v. L-NAME and after inhalation of NO (40 ppm) for 10 minutes Arterial and mixed venous blood gas tensions were also measured

Results and Discussion: Percentages of increase of PaO_2 and LPBF with each treatment are shown in table 1. NO alone produced a significant increase in PaO_2 and in LPBF Intravenous L-NAME alone increased blood flow to the ventilated lung, without significant effect on PaO_2 The association of both treatments resulted in a dramatic and significant increase in PaO_2 and LPBF compared to basaline period and to NO inhalation alone

Table 1 Increase in PaO_2 and LPBF

	NO	L-NAME	L-NAME + NO
PaO_2 (%)	13 4 (1 9)*	10 1 (6 8)	76 7 (12 1)*a
LPBF (%)	10 9 (3 2)*	38 7 (10 7)*	78 6 (13 1)*a

Mean (SE), *$P < 0\ 05$ versus basal values, a$P < 0\ 05$ versus NO values (t-test)

Conclusions: The association of L-NAME and NO has a synergistic effect upon gas exchange and redistribution of pulmonary blood flow in this model of OLV

A.254 Role of endogenous nitric oxide in the adaptation of the pulmonary arterial bed to one-lung ventilation during thoracic surgery

E del Barrio, G Varela, P G Cosmes, M. Jiménez, C Muriel *Hospital Universitario, Salamanca, España*

Background and Goal of Study: NO is now stablished as a biological mediator of clinical relevance (1) Its role as mediator in the pulmonary vascular changes following acute hypoxia is not well stablished (2) The aim of this study is to evaluate the changes in the endogenous NO concentrations during one lung ventilation (OLV) and its effects on the pulmonary haemodynamics.

Materials and Methods: A prospective study was carried out on 20 patients (experimental group) during pulmonary resection under OLV, and 10 cases (controls) during mediastinoscopy using conventional ventilation In the experimental cases, a Swan-Ganz catheter was inserted To evaluate the endogenous NO production, measured as concentration of nitrite ions by a cuantitative colorimetric assay (Griess reaction), in the experimental group a blood sample was obtained from superior cava vein after anaesthesia induction and 10 minutes after the onset of OLV, in control group, the blood samples were obtained at equivalent period. At the same periods of time, hemodynamic parameters were measured in the experimental group, pulmonary artery pressure (PAP), cardiac index (CI), pulmonary vascular resistance (PVR) were registered In both groups, mean values of each variable were compared using a paired-T-test and analysis of variance.

Results and Discussion: In the experimental group, nitrite concentration increased significantly from 7 1 μM to 12 7 μM after OLV ($p = 0\ 02$). In the control group, no differences were found at the same times (8.7 and 8 1 μM respectively). The PAP did not change significantly after OLV (19 and 18 4 mmHg) PVR showed a significant decrease after OLV (163 46 and 134.2 din seg/cm –5, respectively, $p = 0.002$). The CI increased significantly from 2.9 to 3 5 (L/min/m2) after OLV ($p < 0.05$)

Conclusion: This study shows an increase of endogenous NO during OLV and a decrease in pulmonary vascular resistance without modification in PAP. These results may be compatible with a role of endogenous pulmonary production of NO in the adaptative vascular pulmonary changes following to an acute hypoxic phenomenon

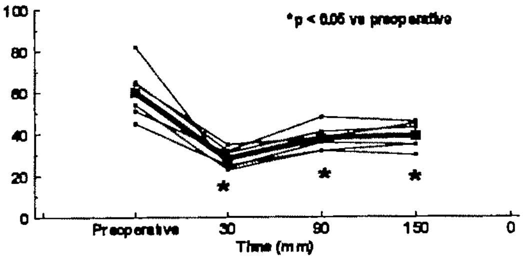
A.255 Effects of thoracoscopy on the immediate postoperative pulmonary function

C Karler, G Bardoczky, M Cappello, A d'Hollander *Departments of Anesthesiology and Thoracic Surgery, Erasme University Hospital, Free University of Brussels, Brussels, Belgium*

Background & Goal of the Study: Thoracoscopy (VATS) became the procedure of choice for many intrathoracic procedures. There are several differences between VATS and standard thoracotomy less postoperative pain and better early pulmonary function. The decrease of FEV1 after VATS is about half that expected after thoracotomy (1) The aim of this study was to evaluate the pulmonary function (PF) in the early postoperative period in patients undergoing lung biopsies by VATS

Materials and Methods: After IRB approval and informed consent, the PF of six male patients (age 50 3 ± 10 6) were studied with a hand-held spirometer (Respiradyne II, Sherwood Med, Watertown, NY) preoperatively and at 30, 90, and 150 min after extubation in the recovery room VATS was performed under general anesthesia with double-lumen endotracheal tube intubation Anesthesia was with intravenous propofol supplemented with sufentanyl and atracurium as muscle relaxants All patients were extubated in the operating room at the end of the procedure All the procedures were performed by the same surgeon Postoperative pain was controlled by 0 5% bupivacaine intercostal blocks in all patients In the recovery room, patients received 40% 02 supplementation Wilcoxon rank sum test was used for analysis FEV1 and FVC are expressed as % of predictive value Values are expressed as median and CI 95%, $p < 0\ 05$ was significant.



Results: The hemodynamic parameters (blood pressure, heart rate), PaO2, PaCO2 and SaO2 were stable during the procedure, and did not change significantly during the postoperative period. The individual FEV1 values are represented in Fig 1. VATS biopsy impaired the PF maximally at 30 min in the postoperative period, when FEV1 and FVC decreased to 52.5% and 53.6% of the preoperative values, respectively. At 150 min after the procedure FEV1 and FVC were improved, but they still remained at 66% and 62% of the preoperative values, respectively.

Conclusion: In contrary to the general belief, there is a significant decrease of FEV1 and FVC in the immediate postoperative period after VATS, even without resection of lung tissue. The degree of impairment is similar as can be seen after lobectomy performed by thoracotomy (2).

A.256 Abdominal wall retractor technique vs pneumoperitoneum laparoscopic surgery. Implications for anaesthetics

C. Vivo, T. Gallen, J. Zunaga, M. Carrau, J Escrig, M. Vila.
Anesthesiology Dep. & Surgery Dep, Hospital General, Castellón, Spain

Objective: The goal of our study is to compare the anesthetics implications of two different techniques for laparoscopy cholecystectomy (LC). classic pneumoperitoneum and abdominal wall retractor technique.

Material and Methods: Two homogeneous groups of patients scheduled for LC. The exclusion criteria were: morbid obesity, severe cardiorespiratory disease and previous abdominal surgery. Group I (n = 20): pneumop. Group II (n = 20). a.w retractor (Ongin®). The same anesthetic technique was used in both groups. Haemodynamics monitoring included the standard, plus non invasive CO through an oesophageal doppler probe (ODM II®). Ventilatory parameters monitored by Capnomac Ultima Datex® Data was collected at prefixed times: T0: 5 min post induction (basal), T1: 5 min post the peumop. or a w retractor was placed (in anti-Tren position). T2: 30 min. later. T3: 5 min post the retractor or pneumop. was removed

Results: Table 1 shows results There are no significative differences between both groups in terms of haemodynamic parameters a discrete ↓ CO and a 20% ↑ of SAP, DAP from basal values was noted at T2. There are statistical significant differences in terms of ventilatory measures in Group I (increase of PIP, PP, Raw and ET-C02 and a decrease in compliance)

Table Changes of ventilation and haemodynamics

	(T0)	(T1)	(T2)	(T3)
CO (N)	5 2 ± 1.4	4.4 ± 1.9	5 2 ± 1 5	5 7 ± 1.7
CO (R)	4 9 ± 1.3	4 5 ± 1 3	5 5 ± 1 8	5 2 ± 1 9
PIP (N)	21 8 ± 5 5	26 3 ± 6 5	26 3 ± 4 7	21 4 ± 3 5
PIP (R)	18 3 ± 2 4	16 8 ± 2 1	17 ± 2	16 8 ± 1.6
PP (N)	16 1 ± 4 8	19 9 ± 6.1	20 9 ± 3 4	16 1 ± 3 5
PP (R)	12 3 ± 2.1	11 8 ± 1.5	11 6 ± 1 7	11 2 ± 1 3
C (N)	45 3 ± 8 8	32 3 ± 7 3	31 6 ± 4 3	43 8 ± 7 9
C (R)	58 1 ± 18	60 2 ± 14 5	59 2 ± 14.6	56 8 ± 12 6
Tiff (N)	84.9 ± 6 5	85 2 ± 6.6	88 2 ± 4	83 9 ± 5 1
Tiff (R)	84 7 ± 6 8	82 5 ± 6 4	84 8 ± 7 5	87.2 ± 6 9

Variables (mean ± SD) N Pneumoperitoneum, R Retractor, CO. Cardiac Output (l/min), PIP. Peak Inspiratory Pressure, PP Plat Pressure (cm H_2O), C Compliance (ml/cm H_2O)

Conclusion: Physiopathological changes induced by lap. surg are well tolerated in healthy patients Nevertheless, in patients with severe cardiorespiratory conditions, the pneumop can produce significant alterations in cardiac and pulmonary functions and the use of pneumoperitoneum should be avoided In those cases the a.w retractor should be the choice due to its minimal physiological changes.

A.257 Oxygen homeostasis during laparoscopic procedures in morbidly obese patients

A Mureganсuro[1], L. Dumont[2], C Mardirosoff[1], M. Mattys[1], V. Picard[2], J. Massaut[1]. *Department of Anaesthesiology, [1]Brugmann University Hospital, Brussels, Belgium, [2]Geneva University hospital, Geneva, Switzerland*

Background and Aim: The cardiopulmonary consequences of the CO2 pneumoperitoneum seem well tolerated in the morbidly obese patients[1, 2] The higher metabolic demand of the MOP results in increased oxygen consumption (VO2). The aim of this study was to analyse the oxygen transport and venous admixture in the MOP during laparoscopic procedure.

Methods: General anaesthesia (sufentanil, N2O 50%, isoflurane) was administered in 13 informed patients (BMI > 40) scheduled for laparoscopic gastroplasty Arterial, venous and mixed venous oxygen content were measured from samples collected into the arterial, central venous line and distal hole of a pulmonary arterial catheter at different times during the procedure. The usual hemodynamic parameters including cardiac output were recorded at the same times. Data were analysed by analysis of variance (MANOVA); the univariate F-Test was used with each patient being his own control. We considered a statistical significance for a $p <$ 0 05

Results and Discussion: CO2 insufflation with an intra abdominal pressure of 17 mmHg did not modify the arterial and venous oxygen content The VO2, SVO2 and DO2 remained in the same range throughout the procedure. Following the release of pneumoperitoneum, DO2 increased (80%, p < 0.01) in combination with an increase in VO2 (88%, p = 0.01) and a slight increase in SVO2 (5%, p = 0.06) This study shows that MOP experienced few changes in oxygen homeostasis during laparoscopy despite an increased metabolic demand and a preoperative disposition to hypoxemia. VO2, DO2 and SVO2 increases were related to the 100% oxygen delivery at the end of anaesthesia.

Discussion: This study confirms that pneumoperitoneum is well tolerated in MOP

A.258 Effect of pneumoperitoneum on Va/Q in laparoscopic cholecystectomy patients

L. Andersson[1], L. Lagerstrand[2], A Sollevi[1], L -Å Brodin[2], S Odeberg-Wernerman[1]. *[1]Dept of Anaesthesia and Intensive Care; [2]Dept of Clinical Physiology, Huddinge Hospital, S-14186 Huddinge, Sweden*

Background and Goal of Study: It has been shown that pneumoperitoneum (PP) reduces venous admixture (as assessed by indirect calculation of the shunt formula) and increases arterial oxygen tension (PaO_2) in cardiopulmonary healthy subjects (1). In the present study, the ventilation-perfusion (V_A/Q) relationships were evaluated by the multiple inert gas elimination technique (2), before and during PP to obtain a direct measure of the pulmonary shunt.

Materials and Methods: After informed consent and approval of the local ethics committee, nine cardiopulmonary healthy patients (ASA I), scheduled for laparoscopic cholecystectomy, (3 males, 6 females) with a mean age of 42 years were included. After premedication and anaesthesia, the patients had a radial arterial line and a thermodilution catheter percutaneously introduced into the pulmonary artery guided by pressure tracing. Six inert gases dissolved in physiologic saline solution were infused at a constant rate into a peripheral vein. After a stabilization period, samples of arterial and mixed venous blood and mixed expired gas were collected The concentrations of the inert gases in the blood and expired gas samples were analyzed by gas chromatography and the retention and excretion of each gas were calculated. The data were processed to get representative distributions of V_A/Q. Measurements were made in the supine position before and after establishment of PP by insufflation of carbon dioxide to an intraabdominal pressure level of 11–13 mmHg. After PP induction, measurements were made in the head-up tilt position and repeated after 30 minutes. Statistical analysis was performed using ANOVA Data are presented as means ± SD, p < 0.05 was considered significant.

Results and Discussion: Induction of PP significantly decreases the pulmonary shunt (p < 0.05) and increases PaO_2, in analogy with a previous study (1). During surgery, the shunt is elevated towards the pre-PP level. The cause of the present changes is unclear. It is suggested that the increased airway pressure may act as an intrinsic PEEP, counteracting atelectasis formation and shunt. Also, a transmission of the increased intraabdominal pressure to the thorax may change local perfusion pressures in favour of an optimized ventilation-perfusion matching, although the diaphragm is shifted cranially by PP.

Position				 30 min
Paw (cmH_2O)	16 ± 4.7	24 ± 4 5*	22 ± 3 6*	22 ± 4 3*
CO (L/min)	4 2 ± 0 7	4 7 ± 1 0	4 0 ± 0 9	4 1 ± 1 1
Shunt (%)	5 8 ± 4 5	4 1 ± 3.2*	3 2 ± 2 8*	5 2 ± 3.4†
PaO_2 (kPa)	21.7 ± 5 8	24 7 ± 4 8*	24 2 ± 4 2*	23 0 ± 4 6
MPAP (mmHg)	13 ± 2	18 ± 2*	9 ± 1*†	13 ± 3†

* denotes significant difference from before PP, p < 0 05, † denotes significant difference from previous measurement

Conclusion(s): In healthy subjects, PP at an intraabdominal pressure level of 11–13 mmHg causes transient reduction of the pulmonary shunt

A.259 Estimating pulmonary shunt fraction in hypercapnic patients using a physiology simulator

J.G Hardman, N M Bedforth, R P Mahajan, A.R. Aitkenhead. *University Department of Anaesthesia, University Hospital, Nottingham, NG7 2UH, England*

Background and Goal of Study: Calculation of pulmonary shunt fraction (Qs.Qt) in patients on the Intensive Therapy Unit (ITU) allows prediction of oxygen requirements and provides a means of assessing disease progression and the effect of interventions [1]. However, pulmonary artery catheterisation is required for its calculation, exposing patients to additional risks The iso-shunt diagram may be used to estimate Qs.Qt from the arterial oxygen tension (PaO_2) and the inspired oxygen fraction (F_IO_2) but is inaccurate during hypercapnia ($PaCO_2$ > 5.3 kPa) because of complex oxyhaemoglobin dissociation and alveolar gas effects. In this study we assessed the ability of a physiological simulator to estimate Qs:Qt in hypercapnic patients receiving intensive therapy.

Materials and Methods: The Nottingham Physiology Simulator (NPS) is a validated computer simulation of original, comprehensive physiological models. Iso-shunt lines have been constructed using the simulator and their agreement with Nunn's iso-shunt diagram is close and consistent Qs.Qt was measured in 20 randomly selected, hypercapnic patients on the ITU in whom a pulmonary artery catheter was present Qs·Qt was subsequently estimated in each subject by entering the PaO_2 and F_IO_2 into the NPS Values for arterial pH, $PaCO_2$ and arterial-venous oxygen content difference ($Ca\text{-}\bar{v}O_2$) were assumed as stipulated by Nunn [1] $PaCO_2$ was then adjusted to the *in-vivo* value by adding simulated deadspace and Qs:Qt was re-estimated in the same fashion 95% limits of agreement ($LA_{95\%}$ = Bias ± 1.96 × SEM of bias) were calculated for each method

Results and Discussion: Accuracy in estimation of Qs:Qt was improved by the inclusion of $PaCO_2$ in 17 of the 20 patients The $LA_{95\%}$ in estimating Qs·Qt was −7.0 ± 3.0% when $PaCO_2$ was assumed as per the iso-shunt diagram and −4.9 ± 2.5% when $PaCO_2$ was included in the calculation. $Ca\text{-}\bar{v}O_2$ was lower in this patient group than is usually assumed in iso-shunt calculations (39 $ml\,l^{-1}$ vs. 50 $ml.l^{-1}$), partly accounting for the consistent underestimation of Qs·Qt by both methods.

Conclusion: Inclusion of the $PaCO_2$ in prediction of pulmonary shunt fraction using the NPS in hypercapnic patients improves accuracy

A.260 Use of a model of gas exchange to infer hypoxaemia in patients with impaired *V / Q*

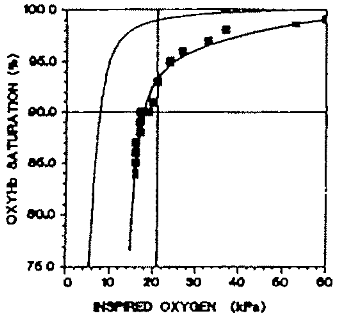
S Snape, S. Bakewell, J.G Jones. *University Department of Anaesthesia, Addenbrooke's Hospital, Cambridge, England CB2 2QQ, UK*

Background and Goal of Study: Commercial aircraft cruise at between 22,000–44,000 ft (1). At 44,000 ft, the cabin pressure is equivalent to that at 8,000 ft and the inspired oxygen pressure (P_1O_2) is 15.2 kPa (116 mmHg) Passengers with impaired V/Q due to acute or chronic lung disease may therefore experience profound hypoxaemia when flying.

We have used a model of gas exchange which describes low V/Q (0 ≤ V/Q ≥ 1) or shunt (V/Q = 0) from the relationship between P_1O_2 and arterial oxyhaemoglobin saturation, SaO_2 (2) We have used the model to infer hypoxaemia in patients with impaired V/Q when flying in pressurised aircraft because shunt and low V/Q have quite different effects on the shape of the curve relating P_1O_2 to SaO_2 (2)

Materials and Methods: 9 patients with chronic lung disease whose SaO_2 on air were ≤94%, were given varying concentrations of oxygen from 15–60% to breath. P_1O_2, SaO_2, ECG and heart rate were all recorded and the results put into the computer model.

Results and Discussion: A typical result is shown This patient had chronic obstructive lung disease with a SaO_2 at sea level breathing air of 93%. This patient had a shunt of 14.6% and a low V/Q effect causing a rightward shift of the curve (from the position of the dissociation curve shown on the left of the diagram) of 8.6 kPa (65 mmHg). This would have predicted a SaO_2 of 87% at 6000 ft cabin altitude, and a SaO_2 of 84% at 8000 ft cabin altitude Similar results were found in 8 other patients with chronic lung disease



Conclusions: The model enabled us to describe, in graphic fashion, the likely effect of altitude on SaO_2 in patients with impaired gas exchange This suggests that this approach may be appropriate in assessing fitness to fly as well as predicting the requirement for oxygen administration when flying.

A.261 Assessment of regional ventilation and determination of time constants in ARDS using dynamic multiscan computed tomography

H U. Kauczor[1], K Markstaller[1], N. Weiler[2], B Eberle[2], W. Heinrichs[2], M. Thelen[1] *Depts. of [1]Radiology and [2]Anesthesiology Johannes Gutenberg University Mainz, Germany*

Background: Oxygenation of patients in ARDS depends critically on the atraumatic recruitment of the alveolar space. Temporal behavior of alveolar volume changes is commonly defined using a one-compartment model of the lung Thus, one single time constant is defined In severe ARDS, we expect the presence of multiple different regional time constants Determination of different time constants could help to define optimal respirator settings and to evaluate new ventilation strategies like High Frequency Oscillatory Ventilation (HFOV). Dynamic Multiscan Computed Tomography (CT) allows for quantitative assessment of ventilated and non-ventilated airspaces with a temporal resolution up to 250 ms

Methods: With institutional approval, five anesthetized pigs (25 kg) underwent controlled ventilation in a CT unit (Somatom Plus 4, Siemens, Germany) after induction of saline lavage ARDS Dynamic multiscan CT acquisitions (slice thickness = 1 mm, high-resolution reconstruction) were performed in a single predefined transaxial plane. To determine regional time constants a single airway pressure step from 0 to 50 mbar was performed Absolute and relative lung areas exhibiting particular CT numbers were calculated planimetrically. The density range from −900 HU up to −500 HU was defined as ventilated parenchyma. A plot of the time dependent fractional increase was used to fit wash-in exponential functions to different curve sections.

Results: Two different respiratory time constants were observed in this ARDS model: One ranged from 0.9 to 1.6 s, the other one from 9.4 to 9.8 s. The slower time constant accounted for approximately 20% of the total recruitable lung area

Conclusions: Dynamic multiscan CT is an adequate method to differentiate at least two time constants in severe ARDS Slower time constants of approximately 10 s are not recruitible by conventional ventilation methods Further studies are required to evaluate new ventilation strategies like HFOV and their effects on total lung recruitment in ARDS

A.262 Measurement of regional alveolar oxygen partial pressure by helium-3 magnetic resonance imaging of the lung

K. Markstaller[1], B. Eberle[2], H.-U Kauczor[1], N. Weiler[2], R Surkau[3], W Schreiber[1], W. Heinrichs[2], M. Thelen[1]. *Depts of [1]Radiology, [2]Anesthesiology and [3]Physics, Johannes Gutenberg University Mainz, Germany*

Background: Recently, MR imaging of lung ventilation using inert noble gases hyperpolarized by high-efficiency optical laser pumping has been described In this study, we aimed to demonstrate· (1) visualization of 100 mL hyperpolarized ^3He administered into the lung under controlled ventilation, and (2) *in vivo* analysis of regional intrapulmonary [O_2] based upon the property of paramagnetic oxygen to destroy ^3He polarization.

Methods: With institutional approval, five anesthetized pigs (27 kg) underwent controlled ventilation in a MRI unit (1.5 T). Using a specifically designed applicator, measured boli of ^3He were administered at the beginning of inspiration A dedicated Helmholtz coil tuned to 48.4 MHz allowed serial ^3He imaging of the lungs during inspiratory apnea. High temporal resolution could be achieved using a Turbo 2D FLASH sequence with short acquisition times of 1 second. Image interpretation was performed analysing transverse supra-diaphragmatic pulmonary cross-sections

Measurements: (i) T1 was determined from the decay of signal intensity in a series of 9 subsequent MR images (ii) The calibration of T1 versus [O_2] was performed by repeating this experiment using an end-tidal [O_2] of 0.16, 0.25, 0.35, 0.45, and varying of ^3He exposure time to oxygen at inspiratory hold (iii) The influence of perfusion on alveolar [O_2] was determined by imaging before and after induction of cardiac arrest

Results: Bolus volumina of 95 ± 4 mL hyperpolarized ^{3}He, positioned at the beginning of inspiration, were administered reproducibly. Longitudinal relaxation time T1 *in vivo* showed a linear correlation to measured end-tidal [O_2] as an effect of oxygen consumption. The absence of perfusion caused T1 derived [O_2] to lineary correlate to the FiO_2 administered

Conclusions: Visualization of small quantities of inhaled hyperpolarized ^{3}He in the lungs is technically feasible Calibration of T1-derived [O_2] values against end-tidal [O_2] and against exposure time to oxygen is possible, allowing regional measurement of intraalveolar [O_2]. Thus, T1 derived measurement of intrapulmonary [O_2] *in vivo* offers an novel instrument for the regional analysis of intrapulmonary [O_2], its time course and hence, its transfer into the blood. In addition, this method shows promise to allow detailed studies upon regional distribution of ventilation for pre- and postoperative assessment of lung function

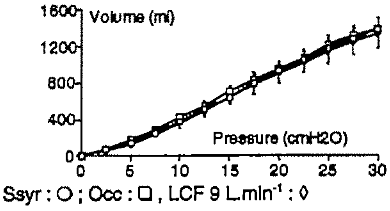
A.263 A comparison of three methods for measuring thoracopulmonary P-V curves in patients with acute respiratory failure

Q. Lu, S Vieira, J. Richecoeur, L. Puybasset, P. Conat, J.J Rouby.
Department of Anesthesiology, La Pitié-Salpêtrière, Paris, France

Background and Goal of the Study: Measurement of respiratory compliance is a good way to assess the severity of ARF (1). It has recently been shown that the use of an automated constant flow of 15 L/min is simple and may avoid the limitations of other methods However, pressure-volume (P-V) curves obtained with this method are shifted to the right because of resistive properties of the respiratory system (2). The aim of this study was to compare the thoracopulmonary P-V curve obtained using a low constant flow of 9 L/min delivered by a ventilator (LCF) with those obtained with supersyringe (Ssyr) and inspiratory occlusion (Occ) methods in patients with ARF

Patients and Methods: 14 patients ($PaO_2/FIO_2 = 172 \pm 92$ mmHg) were studied. Measurements were performed in ZEEP Ssyr method was performed by recording plateau airway pressure corresponding to 50 ml volume steps Occ method was performed by measuring end-inspiratory pressure corresponding to 100 ml increments in tidal volume administered in random order LCF method was performed by using a ventilator (Cesar, Taema) delivering a constant flow of 9 L/min (I/E 80%, FR 5/min) during 9.6 s. For each method, intrinsic PEEP (PEEPi) was subtracted from the P-V curve and the volume corresponding to 2.5 cmH_2O increments pressure was computed

Results: As shown, the thoracopulmonary P-V curves obtained after subtraction for PEEPi from Ssyr, Occ and LCF were similar. Slope and lower inflection point were also not significantly different between the 3 methods.



Ssyr : O ; Occ : □ , LCF 9 $L.min^{-1}$: ◊

Conclusions: Resistive phenomena is not observed when using a low constant flow of 9 L/min LCF is a simple and reliable method for measuring the thoracopulmonary P-V curve.

TRANSFUSION AND HAEMOSTASIS

A.264 Effect of overnight sedation with lorazepam on preoperative stress in cardiac surgery

C.J. Gilhooly, K.S. James, N B Scott *Departments of Anaesthesia, Glasgow Royal Infirmary & HCI International Medical Centre, UK*

Background & Goal of Study: This study assessed the effect of overnight sedation with lorazepam on the endocrine response to stress, measured by urinary catecholamines, plasma glucose and plasma cortisol.

Material & Methods: With ethics committee approval, 50 patients scheduled for coronary artery bypass grafting were entered into a prospective randomised study. Patients were randomised into two groups, A and B. At 20.00, the night before surgery, both groups had baseline linear visual analogue anxiety scores (LVAAS), serum glucose and cortisol levels checked. After catheterisation, 12 hour analyses of urinary adrenaline, noradrenaline and dopamine were measured. At 22 00 Group B were given 50 µg/Kg Lorazepam, Group A received nothing. At 06:00 the next morning both groups were scored for sedation and quality of sleep before receiving temazepam. At 08:00 LVAAS, serum glucose and cortisol were repeated. Non parametric data was analysed using Mann Whitney and Chi squared tests.

Results & Discussion: Measured plasma cortisol and glucose were similar over the study period in both groups Urinary noradrenaline (p = 0.04) and dopamine (p = 0.01) levels were increased in group B but urinary adrenaline levels were similar. Patients in group B had higher sedation scores overnight (p = 0.01), better quality of sleep (p = 0 0002) and less morning anxiety (p = 0.01). The observed increase in urinary catecholamines could be either a physiological response to sedation or a pharmacological response to lorazepam.

Urinary catecholamine	Group A n = 22	Group B
Adrenaline nmol/12 h	19 (15–23)	23 (19–34)
Noradrenaline nmol/12 h	96 (79–132)	150 (96–183)
Dopamine nmol/12 h	670 (514–737)	827 (624–1071)

All values shown as median (and interquartile range)

Conclusions: Improved sleep observed with lorazepam is associated with less anxiety but no reduction in the endocrine stress response. Sedation with lorazepam appears to increase the secretion of urinary dopamine and noradrenaline.

A.265 Cytokines and corticoadrenal response in elective coronary artery bypass grafting and heart transplantation

G. Marco, M.J. Sánchez, R. Calderón, R. Pérez-Reiner, F. Carrascosa, P Monedero, I. Olavide, J.L Arroyo. *Department of Anaesthesiology, University Clinic, University of Navarra, Pamplona, Spain*

Background and Goal of Study: The scope of cytokine biology is fascinating with widespread applications anticipated in many areas of medical science, including anaesthesia[1].

During cardiac surgery cytokines may affect the immune response and are therefore of diagnostic and therapeutic interest[2].

Our purpose in this study was to evaluate the release and relationship of cortisol, IL-6 and IL-8 in CABG and HTx.

Materials and Methods: Once we got the ethical approval, 20 male patients (aged 48–64) with coronary disease scheduled for elective CABG and other 20 for HTx (aged 45–70) were included in the study.

Blood samples for cortisol, IL-6 and IL-8 determinations were obtained in baseline conditions, at the end of the surgery and the first and second postoperative days (24 H and 48 H respectively). Aortic crossclamping time was also considered.

Aprotinin was employed as antifibrinolytic agent in both groups.

All HTx patients received same immune suppressive drugs: methylprednisolone, cyclosporine and azathioprine, without cytolytic agents

Cytokines (pg/ml) were measured by EIA method (R&D systems, Oxon, UK) and cortisol (µg%) by RIA

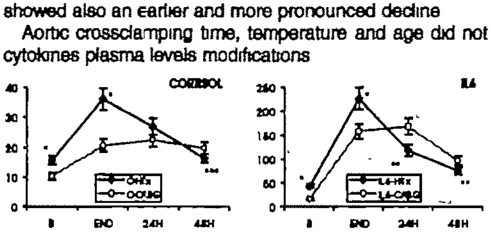
Statistical significance ($\alpha = 5\%$) was determined by ANOVA and Unpaired Student-t tests.

Results: Cortisol and interleukines baseline plasma levels were higher in the HTx group than in the CABG one.

Cytokines and cortisol plasma levels rose significantly after both surgeries and then progressively declined in the postoperative period

This elevation was more important in patients undergoing HTx and showed also an earlier and more pronounced decline

Aortic crossclamping time, temperature and age did not correlate with cytokines plasma levels modifications



Conclusions: The increase in proinflammatory cytokines (IL-6 and IL-8) plasma levels is more pronounced in patients undergoing HTx than those for CABG.

In the HTx group the cytokines release may also have been influenced by immune suppressive therapy.

The same phenomenon appears when cortico-adrenal response is considered, showing a parallelism with the inflammatory one

A.266 Postoperative plasma concentrations of procalcitonin and C-reactive protein after cardiothoracic surgery with and without extracorporeal circulation

M Meisner, K Tschaikowsky, A Hutzler, J Schmidt, F Hang[1], J von der Emde[1]. *Univ of Erlangen-Nuremberg, Dept of Anaesthesiology, [1]Dept of Cardiac Surgery, Krankenhausstr 12, D-91054 Erlangen, Germany*

Background and Goal of Study: The protein procalcitonin (PCT) is induced in the plasma of patients with severe bacterial infection or systemic inflammation As presently known, bacterial endotoxins are the main inductor of PCT To use PCT as a diagnostic tool also in the postoperative period, plasma concentrations should not substantially be induced by the surgical trauma or by extracorporeal circulation (ECC), as known by other parameters of the inflammatory response Thus, we analyzed postoperative PCT concentrations after cardiac and thoracic surgery with and without ECC in patients with a regular postoperative course

Methods: PCT and CRP was prospectively measured 5 days postoperatively in 25 patients undergoing cardiac surgery with ECC and 12 patients with thoracic surgery without ECC with a regular postoperative course and no signs of inflammation or infection

Results: During the 5-day postoperative observation period in 56% of patients undergoing cardiac surgery PCT was >0 5 μg l^{-1} (median 0 74 μg l^{-1}) and >2 0 μgl^{-1} in 8% of patients (67% and 8% after thoracic surgery, median 0 58 μg l^{-1}) PCT was not significantly different in cardiac and thoracic surgical patients (p = 0 76, MWU-test) and there was no correlation with the duration of ECC. The maximal concentration of PCT observed was 2 98 μg l^{-1} for cardiac surgery and 4 96 μgl^{-1} for thoracic surgery CRP increased in all patients observed (median 195 mg l^{-1} for cardiac surgery, 133 mgl^{-1} for thoracic surgery, p = 0 02)

Conclusion: Assessing postoperative plasma concentrations, a moderate increase of PCT (0.5–2.0 μgl^{-1}) must be encounted in the majority of patients Since up to 100-times higher concentrations of PCT are observed after bacterial infections as compared to cardiothoracic surgery, this parameter – other than CRP – obviously can be used for diagnosis of infection or inflammation also postoperatively after cardiothoracic surgery and ECC However, further studies should evaluate the sensitivity and specifity of postoperative increased PCT indicating infections or other postoperative complications

A.267 Increased von Willebrand factor after low molecular weight hydroxyethyl starch priming solution in cardiopulmonary bypass

W. van Oeveren, A Hagenaars, I. Tigchelaar, W. Siemons, R C G G. Huet *Blood Interaction Research and Cardiothoracic Anesthesiology Groningen/Zwolle, The Netherlands*

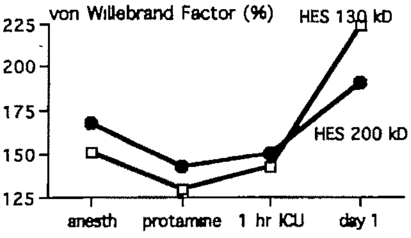
Background & Goal of Study: Most artificial colloids have a reputation of impairing hemostasis However, it was found that a 200 kD hydroxymethyl starch (HES) is as good as human albumin with regard to hemostasis during hemodilution in cardiopulmonary bypass (1), while others reported impaired hemostasis after high molecular weight (450 kD) HES infusion (2).

The availability of functional Factor VIII/von Willebrand Factor (vWF) appears to correspond importantly with hemostasis after cardiopulmonary bypass It increases the rate of intrinsic and extrinsic clotting and increases platelet adhesion to damaged capillaries After cardiopulmonary bypass with the use of albumin prime the concentration of vWF increased one hour after CPB and the first postoperative day (3)

We questioned whether two different medium molecular weight HES soultions affect vWF concentration and whether their molecular weight corresponds with hemostatic function

Patients & Methods: In a prospective randomised double blind study 49 patients received up to 3000 ml of HES with a Mw of 200 kD or with a Mw of 130 kD as heart-lung machine priming solution and as perioperative infusion Perioperatively blood samples were collected for determination of hemostatic variables Bloodloss was monitored per and postoperatively

Results: We found that vWF concentrations (Fig) as well as aPTT and platelet number increased in both groups, but significantly more in the HES 130 kD group. Blood loss was lower in the HES 130 kD group.



Conclusion: The molecular weight of HES has important effects on hemostasis A new medium molecular weight HES (HES 130/0.4) has no negative effect on hemostatic function when used in large quantities during cardiopulmonary bypass

A.268 Blood transfusion and coagulation after autologous platelet-poor plasma transfusion in CABG patients

E. Kafer, S Schwarz, H. Jellinek, R D Fitzgerald *Dept of Anaesthesia and Intensive Care, City of Vienna Hospital Lainz, L Boltzmann Institute for Economics of Medicine in Anesthesia and Intensive Care, Vienna, Austria*

Background: Haemodilution and the retransfusion of platelet rich plasma is used for the reduction of perioperative blood loss However, plasmatic coagulation is not supported by this method Using a platelet poor plasma (PPP) containing about 60–80% of plasma proteins we investigated the changes in plasma proteins and clotting factors after transfusion We hypothesised that the use of PPP leads to a reduced need for substitution of clotting factors and/or red blood cells (RBC) after extracorporeal circulation

Patients and Methods: 40 patients (2 f, 38 m, median 63 y, ASA III–IV) scheduled for CABG were randomised into 2 groups Group A with and Group B without haemodilution and retransfusion of PPP Anesthesia was induced with midazolam, etomidate, and sufentanil and maintained by continuous infusion of propofol/sufentanil Paralysis was achieved by pancuronium bromide Haemodilution was performed after the induction of anaesthesia with the use of HES 450 000/0 7 and a Cobe Brat 2 autotransfusion device PPP was retransfused during sternal closure Blood samples we collected at 5 min, and 7 and 14 h after retransfulon for platelet count and coagulation testing A level of <9 g/dl hemoglobin was regarded as trigger for transfusion of packed RBCs Data were statistically evaluated by ANOVA

Results and Discussion: No differences in age, bodyweight, haematocrit pre or post op, or time of extracorporeal circulation were detected between the groups Group A showed a significantly higher Quick's test (p = 0 027) and fibrinogen plasma levels (p = 0 017) after retransfusion of PPP and required less RBC transfusion intraoperatively (p = 0 025). This effect could not be found at the later timepoints, but ATIII was higher in Gr A at 14 h postop (p = 0 017) Group B required substitution of clotting factors in 3 patients and ATIII in one patient, whereas no substitution was necessary in Group A

Conclusion: We conclude that haemodilution and retransfusion of PPP leads to an improvement of coagulation parameters and reduction of RBC requirements.

A.269 Reduction of blood utilization in cardiac surgery

Juan C. Catalá, José LLagunes, Eva Mateo, Pedro Mann, Juan J. Peña, Edmundo Febré, Ignacio Marqués, Federico Aguar *Department of Anaesthesia, Hospital General Universitario, Valencia, Spain*

Background and Goal of Study: In order to reduce homologous blood requirements, intraoperative haemodilution and aprotinin are used in cardiac surgery The aim of this study was to evaluate the efficacy of additional strategies of saving blood

Methods: This is a prospective observational study in which 89 consecutive patients were included during three months We excluded the patients with ascending aortic aneurism and emergencies. The patients were divided in four groups control group (C) (n = 39), predeposit group (PD) (n = 11), predeposit and cell saver group (PDCS) (n = 19), and a cell saver group (CS) (n = 20) In demographic data, the age was significantly lower in the PDCS group in comparison with the control and CS groups, but no other differences were found All patients received the same anaesthesia technique and the same aprotinin dosis (2 10^6 UIK) while priming the CBP The haemoglobin level was analyzed before operation and at the discharge from the hospital We evaluated the number of units of red blood cell concentrates (RBC) required during the operation and during the subsequent stay in the hospital. Median values and standard deviation are given. ANOVA was used to compare blood bank transfusion requirements between groups

Results and Discussion: Preoperative haemoglobin levels were lower in the autotransfusion groups ($p < 0\ 05$) than in the other two groups, but this is by predonation. Units of RBC transfused were 2.2 ± 1 7, 0.2 ± 0 6, 0 2 ± 0 6, 1.1 ± 1 in group C, group PD, group PDCS and group CS, respectively Requirements of RBC were significantly higher in the control group 51% of all patients were not transfused with RBC. The percentage of patients not transfused in each group were 23% in group C ($p < 0.05$ against groups PD and PDCS), 90% in group PD, 90% in group PDCS and 45% in group CS.

Conclusion: The use of predeposited autologous blood and/or cell saver decreased the blood bank consumption and increased the proportion of patients not transfused with homologous blood.

A.270 High dose aprotinin in complex total hip arthroplasty

M A. García-Enguita, J.P. Ortega, C. Gómez, S Rasal, A Pascual, A. Uneta-Solanas *Department of Anesthesiology, Hospital Miguel Servet, Zaragoza, Spain*

Background: Previous studies have demonstrated that utilization of aprotinin (AP) reduces blood loss during elective total hip arthroplasty (THA). The aim of our study was to asses the effects of AP on blood loss and the need for homologous transfusion (RBCu) in another population of patients at increased risk of blood loss, those undergoing complex THA: revision THA (rTHA) or bilateral primary THA (bTHA)

Methods: After informed consent 30 consecutive patients undergoing elective cementless rTHA or bTHA performed under combined epidural and light general anaesthesia were randomly allocated into 2 groups SF (infusion of saline. $n = 15$) and AP (infusion of aprotinin. $N = 15$). Before induction of anaesthesia a test dose of 5 ml of the study drug was administered over 2 minutes followed by a continuous infusion (loading dose 2 million KIU of AP or 200 ml of saline over 30 minutes followed by 0.5 million KIU h^{-1} of AP or 50 ml.h^{-1} of saline) for the duration of surgery Patients with impaired coagulation or renal function were excluded. Intraoperative blood loss was estimated by measuring the volume in the suction bottles and counting sponges, postoperative blood loss was measured from the surgical drains Transfusion criteria for RBCu were defined prospectively, the amount of transfused RBCu were totalled for the duration of hospitalization. Values are expressed as mean ± SD and groups were compared using the unpaired Student t test, a $p < 0.05$ was considered significant

Results: Demographic data and duration of surgery were similar in both groups. Postoperative blood loss and RBCu transfused were significantly decreased in group AP (Table 1)

Table 1

	Group SF	Group AP
Intraoperative blood loss (ml)	1236 ± 649	1094 ± 297
Postop blood loss (0–6 h) (ml)	530 ± 202	261 ± 110*
Postop blood loss (6–24 h) ml	256 ± 102	201 ± 97
Total blood loss (ml)	2021 ± 723	1576 ± 452
Total RBCu	4.2 ± 1.9	2.3 ± 2.1*

$p < 0.05$

Conclusions: This study allows us to conclude that high dose AP treatment resulted in significantly less postoperative blood loss and in a significant reduction in blood transfusion

A.271 Aprotinin administration reduces blood loss and transfusion requirements in patients undergoing total hip arthroplasty

J.V. Llau, G. Aguilar, J. Solveres, M.F. Minguez, T. Saz, F.J. Belda.
Anaesthesia and Critical Care Dept Hospital Clinico Universitario, Valencia, Spain

Background: Total hip arthroplasty may be associated with large blood loss, requiring homologous transfusion. The aim of this study was to evaluate the efficacy of aprotinin administration in the reduction of bleeding and transfusion requirements, using lower doses than recommended in other studies[1, 2].

Methods: After Institutional approval, written informed consent was obtained from 20 ASA I/II consecutive patients scheduled for primary total hip arthroplasty by the same surgical team. The patients were randomized to receive either 2×10^6KIU aprotinin during 30 minutes ($n = 10$) or normal saline ($n = 10$) in the same volume and time immediately after anaesthesia induction. Both groups received a standardized induction with fentanyl 4 μg/kg, propofol 2.5 mg/kg and vecuronium 0.1 mg/kg. Anesthesia was maintained with 60% N_2O in oxygen, isoflurane 0.5–1%, plus intermittent injection of vecuronium and fentanyl as required. Operative blood loss was determined at the end of surgery by measuring the volume of blood in the suction pump and by weighing surgical swabs. Postoperative blood loss was measured from surgical drains 24 hours later. Haemoglobin (Hb) and Haematocrit (Htc) were measured before and after surgery and when considered necessary. The patients were transfused 1 packed red cells (PRC) when $Hb < 9$ g%. Hb was determined two hours after each PRC transfusion. Enoxaparine 40 mg sc. was started 8 hours after surgery for thromboprophilaxis and given daily. Patients were daily examinated for signs of deep vein thrombosis (DVT) until hospital discharge. Results are expressed as mean ± SD Unpaired t-test and Mann-Whitney U test were used for statistical analysis A P value < 0.05 was considered statistically significant

Results: Our results are presented in the table. Bleeding reduction was 28.5% intraoperative and 30.5% postoperative No patients in the aprotinin group were transfused. No clinical DVT was observed.

Age (yr)	Aprotinin 68 ± 8	Placebo 67 ± 7
Initial hematocrit	42.1 ± 3.7%	41.0 ± 4.8%
24 h postoperative Hto	34.3 ± 3.7%	30.4 ± 3.3% (*)
Initial hemoglabin	14.3 ± 1.2 g%	14.1 ± 1.4 g%
24 h postoperative Hb	11.6 ± 1.2 g%	10.1 ± 1.2 g% (*)
Intraoperative bleeding	557 ± 165 ml	780 ± 373 ml (*)
Postoperative bleeding	265 ± 143 ml	396 ± 247 ml
Total bleeding	817 ± 147 ml	1177 ± 325 ml (*)
Patients transfused	0	3 (*)
Number of PRC transfused	0	6 (*)

(*) $p < 0.05$

Conclusion: The use of aprotinin in our protocol during primary total hip arthroplasty results in a reduction in intraoperative blood loss and less transfusion requirements. Aprotinin's dosage remains to be elucidated.

A.272 Use of high-dose aprotinin during spinal surgery results in a reduction in both blood loss and the amount of blood transfused

Csaba Fejér, Miklós Mezofi, Péter.-Pál Varga. *Central Military Hospital of the Hungarian Army; Budapest, Hungary*

Background: Aprotinin, a serine proteinase inhibitor, has been reported to reduce blood loss significantly in patients undergoing cardiac[1] and total hip replacement surgery[2]. There was no data in the literature about the efficacy in spinal surgery associating with substantial blood loss requiring transfusion of several units of blood So we investigated the effect of aprotinin on blood loss and transfusion requirement and the potential side effects in a special type of spinal surgery

Methods: Forty patients scheduled for thoracolumbar transpedicular (TLT) fixation of spine because of spondylolisthesis were randomized to receive, in double-blind method, either aprotinin given as a bolus of 2×10^6 kallikrein inactivator units (KIU) in 30 minutes followed by an infusion of 5×10^5 KIU/h until the end of surgery or an equivalent volume of normal saline. Anesthesia and surgical techniques were standardized. Intentional preoperative normovolemic hemodilution, systemic deep venous thrombosis prophylaxis and systemic antibiotic prophylaxis were used. Intra- and postoperative blood loss and transfusion were measured. Perioperative hematocrit and hemoglobin values, renal and hepatic function were also measured. Results are expressed as the mean ± standard deviation For the statistical analysis we used Student's t test and the Mann-Whitney test.

Results: Aprotinin reduced total blood loss from 1938 ± 463 ml to 1167 ± 165 ml ($P < 0.005$) This reduction of blood loss occurred during surgery ($P < 0.005$) and postoperatively ($P < 0.001$). There were 48 units of packed red cells transfused for 12 patients in the control group and 15 units transfused for 5 patients in the aprotinin group ($P < 0.001$). One transient bronchospasm was occurred in the aprotinin group and no Incidence of deep venous thrombosis was observed in the two groups

Conclusion: The use of high-dose aprotinin combining with intentional preoperative normovolemic hemodilution results in a significant reduction in both blood loss and the amount of blood transfused.

A.273 Blood loss reduction with aprotinin during spinal instrumented surgery

Rosso M. Tommasi, M. Granell, R. García-Aguado, F. Petrini, F. Grau, J.M. Palanca, G. Martinelli. *Dep. Anaesthesia, Critical Care and Pain Relief, University General Hospital, Valencia, Spain; Dep. Anaesthesia and Critical Care, Policlinico S Orsola-Malpighi, Bologna, Italy*

Background & Goal of Study: Surgical procedures involving instrumented spinal fusions generally requires blood transfusion. We undertook a preliminary study of high-dose aprotinin for posterior lumbar fusion to confirm the beneficial effects of aprotinin on blood loss during spinal surgery.

Material & Methods: 20 adult patients scheduled for elective lumbar spinal surgery, were randomly assigned to two groups: group A (n =

10) received aprotinin, group B (n = 10) received placebo Surgical and anaesthesia techniques were standardised Both the surgeon and the anesthesiologist were unaware as to whether patients were receiving aprotinin or placebo.

After induction of anaesthesia, patients of group A received a subcutaneous dose test of aprotinin (50 000 kallikrein inactivator units, KIU) to refuse allergic responses; then, was given a bolus injection of 2 × 10^6 KIU over 30 min, followed by an infusion of 5 × 10^5 KIU/h until the end of surgery, with a maximum dose of 3 × 10^6 KIU. In group B was administered the same volume of normal saline according to the same protocol

We estimated perioperative blood loss by measuring the volume in the suction bottles and counting sponges (±5 ml/sponge). At the end of surgery, the surgeon evaluated bleeding on a five-point rating scale. Statistical analysis was performed using Student's *t* test and the chi-square test Results are expressed as mean ± standard deviation

Results: Total blood loss was significantly lower in group A (P < 0.01) This reduction in blood loss was clinically evident: the bleeding intensity score given by the surgeon was significantly less for the goup A patients (P < 0 01) No side effects due to aprotinin were recorded No surgical or postoperative complications were registered.

Conclusions: In our study, in patients undergoing lumbar spinal fusion, aprotinin in high doses (as recommended for cardiac surgery) resulted in a significant decrease of perioperative bleeding, with better condition of surgical field. Further investigations, could determine the optimal dosing regimen of aprotinin to reduce the requirement for blood transfusion in spinal fusion

A.274 Aprotinin: prevalence and predictive factors for the presence of specific antibodies. A study of 520 cardiosurgical patients

A.M Scheule, W Beierlein, S Arnold, H P Wendel, F S Eckstein, G. Ziemer. *Dept of Surgery, Div. of Thoracic, Cardiac, and Vascular Surgery, University of Tuebingen, Germany*

Background and Goal of Study: Aprotinin is increasingly used in all surgical disciplines as an antifibrinolytic agent either systemically or locally as a stabilizer of commercially available fibrin tissue adhesives. Both application modes can induce the formation of aprotinin-specific antibodies[1]. The presence of aprotinin-specific antibodies is considered to be a risk factor for life-threatening anaphylactic reactions at reexposure[2]. The aim of this retrospective study was to find out the prevalence of aprotinin-specific antibodies in patients scheduled for cardiac surgery

Material and Methods: The preoperative sera of 520 patients (mean age 62 ± 13 years, 68% coronary artery disease, 28% valve disease) were screened for aprotinin-specific IgG using a standard ELISA. The IgG positive sera were analyzed also for IgE employing a fluorescence enzyme immunoassay A history of previous surgical procedures was taken focussing on aprotinin-preexposure and surgical procedures

Results and Discussion: 22 of 520 (4%) patients were positive for aprotinin-specific IgG antibodies Only three of these (14%) had a documented preexposure Ten patients (10/22) had undergone relevant surgical procedures either in cardiovascular surgery (4/10), or in otorhinolaryngology (ENT, 3/10), or in both (2/10), or in traumatology (1/10) Aprotinin was administered in all patients. One patient having had a recent systemic preexposure in cardiac surgery, presented now with a severe anaphylaxis She was the only being preoperatively positive for both, aprotinin-specific IgG and IgE antibodies, as revealed by retrospective analysis. Surgical history, especially cardiovascular and ENT procedures, seems to be more indicative for aprotinin-preexposure than documentation in the chart. A possible explanation may be insufficient documention of aprotinin use, particularly as a component of fibrin sealants.

Conclusion: In patients with this anamnestic profile measures to avoid anaphylactic reactions are stringent at reexposure to aprotinin.

A.275 Influence of aprotinin in the proinflammatory cytokine response to elective cardiopulmonary bypass

M J Sánchez-Ledesma, G Marco, A Panadero, J I Fernandez-Liesa, M.J. Iribarren, P Monedero, F Carrascosa *Department of Anaesthesioloy University Clinic, University of Navarra, Pamplona, Spain*

Background and Goal of Study: Proinflammatory cytokines have been implicated as mediators of multiorgan disfunction after CPB[1,2] On the other hand, aprotinin which is frequently used as antifibrinolytic agent in coronary artery bypass grafting (CABG) may have immunologic effects

The purpose of this study was to evaluate the influence of aprotinin on the release of IL-6, IL-8 and TNF-α during CABG and in the earlier postoperative period

Patients and Methods: After institutional ethical committee approval, 36 patients (aged 48–64), undergoing CABG were randomized in two groups with or without aprotinin· Control group (CG) n = 18 and Aprotinin group (AG) n = 18, respectively. There were no differences in age, weight, sex, corporal surface and anaesthetic-surgical management

Blood samples for IL-6, IL-8 and TNF-α determinations were obtained in baseline conditions, at the end of surgery, 24, 48 and 72 postoperative hours. Haemodinamic data, aortic crossclamping time and temperature were also considered All cytokines were measured by enzyme immunoassay method (R&D systems, Oxon, UK)

Results were shown as (MEAN,SD) and statistical significance (p < 0 05) was determined by ANOVA and Unpaired Student-t tests

Results: Proinflammatory cytokines plasma levels rose significantly in both groups (p < 0 0001 for IL-6 and IL-8, p < 0 05 for TNF-α) at the end of surgery and progressively declined during the following postoperative days TNF-α showed the less remarkable modifications

There was no correlation between cytokines increase and aortic crossclamping time or temperature

In the aprotinin group, the increase in plasma levels of IL-6 (24 h) and IL-8 (24 h & 48 h) were significantly lower compared with the control group There were no differences in TNF-α plasma levels in the aprotinin group

pg/ml	IL-6 (CG)	IL-6 (AG)	IL-8 (CG)	IL-8 (AG)	TNF-α (CG)	TNF-α (AG)
Baseline	15 1, 23 3	8 5, 3 3	63 6, 27	55, 14 1	7, 2 2	7 3, 1 8
24 h	235 6; 33 9*	158 4, 50*	156 2, 82 2*	100, 47 8*	10 2, 3 6	9 5, 4 1
48 h	188 2, 49	169 4, 58	150 1, 53 2*	82 8, 47 2*	9 5, 3 9	7 8, 2 8
72 h	107 3; 51 5	97 4, 45 3	88 5, 40 3	68 3; 32 5	9 1, 4 6	8, 2 6

* = *p < 0 05*

Conclusions: Proinflammatory cytokines IL-6 and IL-8, specially the former, are good indexes to evaluate stress response to CPB

Aprotinin may influence the release of proinflammatory cytokines.

The role of aortic crossclamping time and temperature in the release of cytokines looks unclear

A.276 Perflubron emulsion delays blood transfusions in orthopaedic surgery

D R Spahn, R. van Bremt, G. Theilmeier, J P. Reibold, M. Welte, C. Dunger-Baldauf, H. Heinzerling, P Kerpert, K Messmer. *Perflubron Emulsion Study Group, Departments of Anaesthesiology, University Hospital Zürich, R. W. Johnson Pharmac Research Inst, Zürich, Switzerland; Leuven, Belgium; Munster, Giessen, Munich; Institute of Surgical Research, University of Munich, Germany; Alliance Pharmac Corp., San Diego, CA, USA*

Background and Goal of Study: Fluorocarbon emulsions have been proposed as temporary artificial oxygen (O2) carriers [1] Aim of the present study was to compare the effectiveness of perflubron emulsion (Alliance Pharmac. Corp, San Diego, CA and R W Johnson Pharmac Research Inst., Zurich, Switzerland and Raritan, NJ) with the effectiveness of autologous blood or colloid infusion in reversing physiologic transfusion triggers.

Materials and Methods: With approval of the local Ethical Committees and written informed consent 147 patients undergoing elective orthopaedic surgery were enrolled in this multinational, multicenter, randomised, controlled, single-blind, parallel group study Patients were monitored with radial artery and pulmonary artery catheters and underwent acute normovolaemic haemodilution (ANH) preoperatively to a target haemoglobin of 9 g/dL During the first stage of operation an inspiratory O2 fraction (FiO2) of 0.40 was used Patients were kept normovolaemic throughout surgery by maintaining their post-ANH PCWP Patients were randomised into one of four treatment groups when reaching a physiologic transfusion trigger such as tachycardia (heart rate >125% of post-ANH or >110 bpm), hypotension (mean arterial pressure <75% of post-ANH or ≥60 mmHg), cardiac output >150% of post-ANH or mixed venous PO2 < 38 mmHg. Treatment in the four groups were 450 ml autologous blood harvested during ANH with FiO2 = 0 40 (AB), 450 ml colloid (gelatin or hydroxyethyl starch) with FiO2 = 1.0 (COL), 0.9 g/kg Perflubron with colloid (total = 450 ml) with FiO2 = 1.0 (P0.9) and 1.8 g/kg Perflubron with colloid (total = 450 ml) with FiO2 = 1 0 (P1 8) The primary endpoint was duration of transfusion trigger reversal A secondary endpoint was percentage of transfusion trigger reversal The logrank test and Fisher's exact test were used (p < 0.05) Data are median (95% CI).

Results: Patient characteristics and baseline data were comparable between treatment groups Perflubron emulsion was well tolerated. Duration of reversal and percentage of reversal were significantly different between the P1.8 and either control group (AB and COL).

	AB	COL	P 0 9	P 1 8
Duration [min]	55 (30–70)	30 (27–60)	59† (40–90)	80*†
Reversal [%]	60	76	82	97$^{\$\dagger}$

* = sign vs AB (adj for multiple testing), † sign. vs COL, $^{\$}$ = sign vs AB

Conclusion: Perflubron emulsion (1 8 g/kg) is more effective than autologous blood or colloid infusion in reversing physiologic transfusion triggers

A.277 Effect of acute normovolaemic haemodilution on allogenic blood transfusion during cardiac surgery: a meta-analysis

P.G. Loubser, I De Juan *Baylor/Methodist Anesthesiology Services, Houston, Texas 77030; Applied Medical Research and Development, Sugar Land, Texas 77478, USA*

Background and Goal of Study: Acute normovolaemic haemodilution (ANH) is used during surgery as a means of avoiding transfusion of allogeneic blood [1] Meta-analysis (MA) is a quantitative review procedure in which a large collection of results from individual studies are statistically analysed [2] This study examined the efficacy of ANH as a blood conservation technique in cardiac surgery using MA.

Material and Methods: A bibliography was assembled by searching the Medline database coupled with cross-referencing from 1966–1997. Human studies in patients undergoing cardiovascular surgery were selected according to study N, control group and reported data. The effect of ANH on transfusion of allogeneic blood products (Sub-study A) and on surgical blood loss (Sub-study B) was examined using Meta-analysis Programs, Version 4 3 (weighted integration and random effects model). $p < 0.05$ was used for statistical significance.

Results and Discussion: Of the 122 publications retrieved, 22 focused on cardiovascular surgery in humans, viz. cardiac surgery; $n = 14$, vascular surgery; $n = 8$. Volume of sequestered whole blood ranged from 450–2100 mLs and was either heparinized or collected in citrate anticoagulant For Sub-study A, 7 eligible trials (sample size – 723) reported that allogeneic blood transfusion requirements were decreased in patients undergoing ANH (mean effect size = 2 0 ± 0 09, $p < 0.001$, homogeneity Q = 676 1, $p < 0.001$; sampling error variance = 1 13%. For Sub-study B, 5 eligible trials (sample size – 351) reported that blood loss decreased in patients undergoing ANH (mean effect size = 0 8 ± 0 11, $p < 0.001$, homogeneity Q = 415.8, $p < 0\ 001$; sampling error variance = 1%). A Fail-Safe N exceeded 25 for both sub-studies

Conclusion: Although these results suggest that ANH is an effective blood conservation technique, the population sample reported above does not meet a test of homogeneity. Over 75% of the variance was due to systematic factors, i.e. study characteristics and variable not identified or reported in studies Therefore, additional trials that tightly control patient sampling and study design are required.

A.278 Pre-autologous blood donation: comparison of red blood cell apheresis and standard whole blood donation in total hip arthroplasty

N Rosencher[1], F Kalfon[2], O Langeron[2], L. Eyrolle[1], A. Belbachir[1], G Wormant[1], J.L. Beaumont[2], G. Fabre[3], C. Conseiller[1]. [1] *Cochin Port-Royal,* [2] *Pitié-Salpetrière,* [3] *Begin, University Hospitals, Paris, France*

Goal: The aim of this study is to evaluate the efficacy and safety of a new PAD technique: Red Blood Cell Apheresis (RBCA), performed 25 days prior to surgery, in comparison with Standard Whole Blood PAD (SPAD). A preliminary study has shown that when Red Blood Cell Apheresis is performed 2 days prior to surgery, it is not more effective than passive intraoperative hemodilution (1). From a quality standpoint, red cell concentrates obtained by apheresis 30 days prior surgery are similar to red cells obtained by manual whole blood collection (2) Efficacy is judged by allogenic blood transfusion reduction and safety by tolerance during and after apheresis.

Patients and Methods: The prospective, multicenter clinical trial included 60 consenting patients (age 18 to 78 years, Hb > 12 g/dl, weight >55 kg, ASA status 1 or 2), scheduled for THA, randomized in 2 groups (RBCA or SPAD) Red Blood Cell Apheresis was performed on a MCS-3P device (Haemonetics® Braintree, MA), by hemodilution at the Blood Bank 25 ± 5 days prior to surgery: only erythrocytes were removed and plasma was reinfused immediately. By reducing haematocrit (Hct) between 30 and 32%, 2 or 3 RBC units were collected from each patient in this group. In the Standard PAD group, autologous whole blood was collected every week up to a maximum of 4 units. All patients received 200 mg of iron sulfate Immediate and late side effects of both procedures were recorded The transfusion goal was set at Hct = 30% from recovery room (D + 3 h) until discharge (D + 8) Results are shown as mean ± SD. Wilcoxon procedure was used for statistical analysis

Results: The 2 groups were similar in age, weight, gender and Hct rate from D + 3 h until D + 8. Early side effects were three mild citrate reactions in RBCA group and one hypotension in SPAD group. Late side effects, such as mild asthenia or light-headedness were not different in the 2 groups.

	RBCA	SPAD
Allogenic transf	*0*	*0*
Autologous transf (ml)	510 ± 161	493 ± 178
RBC collected/patient (ml)	630 ± 167	555 ± 141
Total Hb collected/patient (g)	128 ± 35	*105 ± 24
Hct (%)/Hb(g/dl) at D-1	39 ± 3/13 ± 1*	37 ± 4/12 ± 1

Conclusion: A single RBC Apheresis performed 25 days prior to surgery is as efficient as Standard PAD in avoiding allogenic transfusion for primary THA. Collection of 3 RBC units in the same course by apheresis is as well tolerated as 3 or 4 sequential whole blood collections. These results are in accordance with previous data about safety (3). This new procedure results in lower frequency of donations and reduced laboratory testing. Furthermore, an enhanced erythropoiesis may be expected.

A.279 Oral iron supplementation increases erythropoiesis in autologous blood donors

S -M. Kasper, H. Lazansky, C. Stark, L. Radbruch, U. Bomer. *Department of Anaesthesiology, Universitat zu Köln, Germany*

Background and Goal of Study: Most autologous blood donors receive oral iron supplementation but the benefit of this therapy is uncertain (1) We compared the efficacy of a standard oral iron supplementation with that of a combined oral plus intravenous iron supplementation in patients undergoing weekly autologous blood donation.

Materials and Methods: This was a single-center, randomized, double-blind, placebo-controlled, parallel-group study One hundred eight iron-replete patients who were scheduled for donation of 3 units of autologous blood at weekly intervals were randomly assigned to receive, in a double-blind fashion, no iron supplementation (placebo), oral iron supplementation (285.6 mg of elemental iron/day), or oral plus intravenous iron supplementation (285 6 mg of elemental iron/day orally + 102.5 mg of elemental iron/week intravenously) RBC production (over baseline production) during the 21-day study period was determined by the total volume of RBCs donated minus the change in circulating RBC volume between the first donation and the end of the study period (2) Data are presented as mean ± standard deviation. RBC production amongst the study groups was compared by one-way analysis of variance followed by Scheffe's test for pairwise comparisons. $P < 0.05$ was considered significant

Results and Discussion: RBC production during the study period did not differ significantly between the two iron-supplemented groups (oral iron group, 331 ± 124 ml; oral plus intravenous iron group, 315 ± 137 ml) RBC production in either iron-supplemented group was significantly greater than in the placebo group (220 ± 124 ml; $p < 0.01$ vs oral iron group, and $p < 0.05$ vs oral plus intravenous iron group).

Conclusion: Oral iron supplementation increased the production of RBCs in autologous blood donors compared with placebo. Additional intravenous iron (102.5 mg of elemental iron once weekly) did not further augment RBC production. This is the first study that demonstrates the efficacy of oral iron supplementation in increasing erythropoiesis in iron-replete autologous blood donors.

A.280 Postoperative blood retrieval and transfusion in total knee arthroplasty

R Asbert, E Udina, O Gomez, D Moreno, H. Ferrer, J Bernal *Dep of Anaesthesia and Orthopedics, Hospital Mutua de Terrassa, Barcelona, Spain*

Total joint arthroplasty is a procedure usually accompanied by significant blood loss requiring transfusion Risks of transfusion include the transmission of viric illness and other important side effects (1) Alternatives to homologous banked blood transfusions are. Predonated autologous transfusion, intraoperative blood salvage, haemodilution and postoperative blood salvage The aim of our study is demonstrate the efficacy and safety of a postoperative blood salvage system in total joint arthroplasty and the reduction of homologous blood transfusion

Methods: We studied prospectively 100 patients undergoing Total Knee Arthroplasty (TKA) using ConstaVac CBCII postoperative blood salvage system, and we compare them to 40 patients undergoing TKA using a standard drainage system (Control Group) All patients received subarachnoidal anaesthesia We analyse the evolution of preoperative, postoperative immediately and at 24 hours postoperatively blood parameters. Amount of salvaged blood, values of haemoglobin of this blood and the volume of homologous transfusion and adverse reactions during and following transfusions were also recorded Exclusion criteria were chronic liver diseases, coagulation disturbances and patients with history of infection and malignant pathology Operative technique with tourniquet, length of surgery and postoperative management were identical in all patients

Results: We included 140 consecutive patients, 40 in control group (CG) and 100 in the study group (SG)

All patients were similar in gender, age, weight and ASA clinical status. Preoperative blood parameters were similar between groups The amount of blood retrieved and transfused averaged 660 ± 275 (250–1800) ml. Homologous blood transfusion was averaged 315 ± 325 ml in CG and 21 ± 108 ml in SG ($p < 0.000001$) Values of haemoglobin at 24 hours were 10 6 ± 1.24 g/dl in CG vs 11.8 ± 1 6 g/dl in SG (p = 0 00004)(2) No secondary effects were recorded

Conclusions: This study indicates that a postoperative blood salvage system safely and effectively reduces the amount of homologous blood requirements and sustains higher hemoglobin levels after operation without adverse effects in patients undergoing TKA

A.281 Intraoperative autotransfusion combined with irradiation of the washed erythrocytes for tumour surgery: experience with 30 patients

S Durrer, G Schuepfer, C. Konrad, H. Gerber *Institute of Anesthesiology, Kantons-Spital Lucerne, Switzerland*

Introduction: As shown by Hansen et al (1) tumor surgery is no longer a contraindication for the intraoperative auto-transfusion, under the condition, that washed erythrocytes are irradiated with a tumoricide dose of 50 Gy to eliminate the always present vital malignant cells.

Method: 30 Patients scheduled for major tumor surgery with a mean blood loss of 2580 ± 1930 ml had 670 ± 360 ml of washed and irradiated (50 Gy) erythrocytes retransfused Repeated measurements of free hemoglobin, lactate dehydrogenase (LDH) and serum potassium as markers of hemolysis were taken during the first 3 hours postoperatively and the patients were closely observed for adverse effects Acute normovolemic hemodilution (ANH) and individualized transfusion limits were additional strategies to reduce allogeneic blood donation

Results: Free hemoglobin levels were <0 8 g/l in all tests, potassium and LDH always within normal limits One Patient developed sepsis due to bacterial over-growth of the retransfused blood. Allogeneic transfusions in the group of 23 total prostatectomies were reduced from 5 9 ± 6 7 to 3 5 ± 3.4 units (by 41%) compared to a retrospective control group (n = 90)

Conclusions: Manipulations of blood products (e g. taking laboratory tests) bear the danger of bacterial overgrowth and should be avoided Irradiation of washed erythrocytes does not result in clinically relevant hemolysis The combination of this technique with ANH and the introduction of individualized transfusion limits reduced allogeneic transfusions at our institution significantly

A.282 Platelet activation during and after major vascular surgery

D. Thiry, I El Alamy[1], M Diaby[2], C M. Samama, P. Conat *Dept. Anest*, *[2]Labo Urgences, Hopital La Pitié, [1]Labo Hémostase, Hopital Hotel Dieu, Paris, France*

Background and Goal of Study: Postoperative platelet activation plays a role in cardiac events following surgery in CAD patients Accordingly, we have performed a prospective study to assess platelet reactivity during and after abdominal aortic surgery

Materials and Methods: After IRB approval and informed consent, 17 patients (mean age 67 yo) were studied. Anesthesia was induced by propofol, sufentanil, and atracurium and maintained with isoflurane Patients treated with aspirin or receiving platelet or plasma transfusion were excluded. Blood samples were drawn before induction (T1), one hr after incision (T2), one hr after extubation (T3), 24 hrs postoperatively (T4), 48 hrs postop (T5), and at day 7 (T6) The following tests were performed at all steps of measurements platelet count, arachidonic acid (AAA) and ADP-induced (ADPA) platelet aggregation and flow cytometry for CD62 (P selectin, alpha granule membrane glycoprotein expression). This glycoprotein is closely related to platelet activation

Results and Discussion: A significant increase in ADP-induced aggregation was observed postoperatively at T4 and T5 and returned to control at T6 indicating an increased platelet aggregability A trend was also observed with arachidonic acid-induced aggregation This was not associated with a change in flow cytometry suggesting that platelet are not activated but are prompt to be activated

	T1	T2	T3	T4	T5	T6
Platelets (G L^{-1})	210 ± 61	186 ± 69	174 ± 60	163 ± 43	156 ± 52	340 ± 105
AAA (%normal)	96 ± 29	98 ± 45	101 ± 67	145 ± 85	137 ± 75	100 ± 12
ADPA (%/normal)	103 ± 29	112 ± 38	104 ± 33	120 ± 29*	127 ± 28*	93 ± 22
CD62 (%/normal)	96 ± 38	75 ± 14	71 ± 16	77 ± 15	92 ± 30	70 ± 7

Statistical analysis Results are expressed as % of normal subjects values – Mean ± SD, *$p < 0.05$ versus T1

Conclusions: Post-operatively, in vascular surgery patients, circulating platelets are not activated even if they are activable as demonstrated by flow cytometry However platelet aggregability is increased demonstrating their high sensitivity to any activation (including stress) These results must be taken into account to limit postoperative cardiac events in vascular surgical patients

A.283 Intracellular storage of hydroxyethyl starch in human endothelial cells *in vitro*

B. Nohe, M. Burchard, C. Zanke, K. Unertl, H J Dieterich *University of Tuebingen, Department of Anaesthesiology,*

Hydroxyethyl starch (HES) is a colloid commonly used for volume replacement during shock or hypovolemia and for hemodilution in order to increase microcirculatory blood flow In man, intracellular storage of HES has been demonstrated in macrophages and in keratinocytes of the skin after long time hemodilution of patients with sudden deafness. The endothelial cell is a critical component in the pathogenesis of shock or reperfusion injury, diseases commonly treated with HES We therefore studied the effects of different concentrations of this colloid on the appearance and kinetics of ingestion and intracellular storage of HES molecules in human umbilical venous endothelial cells (HUVEC) in vitro

Methods: Confluent HUVEC were incubated for various periods of time (1–72 hours) at 0 5–20 mg/ml with FITC conjugated HES 200/0 5 (FITC-HES). The amount of intracellular stored HES was quantified by the emitted fluorescence of the FITC-HES molecules, using flow cytometry The morphology of intracellular storage was studied by fluorescence microscopy Cells with medium alone, FITC-supplemented medium and FITC-supplemented medium with unconjugated HES 200 served as controls To evaluate the long time storage, a further group of cells was incubated with FITC-HES and afterwards cultured for 5 days in FITC-HES free medium

Results: Incubation with FITC-HES resulted in a remarkable degree of intracellular storage in HUVEC Intracellular stored HES showed a typical morphology of numerous intracellular, fluorescent vesicles The degree of storage seemed to be both, time and concentration dependent The morphological picture was caused by the HES molecules themselves, since incubation with FITC-supplemented medium, either with or without unconjugated HES resulted in a completely different morphological picture This excluded the possibility that HES leads to vesicle formation of other components than the HES molecule itself The storage of HES molecules seems to be irreversible, since the emitted fluorescence after 5 day culture in HES-FITC free medium decreased only to a little degree, which can be contributed to the well known bleaching of FITC under the conditions of 37°C in an incubator

Conclusion: HES is stored in a concentration and time dependent manner in endothelial cells Once stored, the cells are not able to reduce the stored amount of HES molecules anymore Because of cumulative effects, application of low concentrations of HES over a long period of time results in a more pronounced storage then a short timed therapy does, even when high doses are applied Regarding the magnitude of storage, it has to be hypothesized that functional changes in these cells are likely to occur Whether this hypothesis holds true and whether the possible functional changes can be beneficial during reperfusion is under investigation in our labaratory

A.284 Hydroxyethyl starch impairs *in vitro* coagulation

T.T. Niemi, A.H. Kuitunen *Department of Anaesthesiology, Helsinki University Central Hospital, Helsinki, Finland*

Background: Haemostatic mechanisms are affected by artificial colloids; hydroxyethyl starch (HES), in particular, may be detrimental to haemostasis[1, 2].

Methods: In a crossover study with ten volunteers Ringer's acetate, 6% low molecular weight HES (MW 120 000/molar substitution ratio 0.7), 10% low molecular weight HES (M_W 200 000/0.5) and 6% high molecular weight HES (M_W 400 000/0.7) or 4% albumin was added to venous blood samples to make either 20 vol.% or 50 vol.% concentrations of each of the solutions. Samples were analyzed by thrombelastography (TEG). The differences were tested with Kruskal-Wallis test

Results: All HES solutions at 20 vol.% concentration impaired haemostasis as demonstrated by decreased clot formation rate (α-angle) and maximum amplitude (MA) In contrast, Ringer's acetate and albumin improved coagulability at 20 vol.% concentrations. Coagulation time (r + K) was prolonged at 50 vol.% dilutions of all solutions. The median r + K was greater with HES 400 ($p < 0.05$) and HES 200 (N.S.) than with HES 120

Conclusion: We conclude that HES at 20 and 50 vol.% concentrations has an adverse effect on *in vitro* measures of coagulation. A 50% dilution with high molecular weight HES seems to impair coagulation more than low molecular weight HES. Ringer's acetate and albumin at 20 vol.% caused a hypercoagulable state by an interaction with or activation of coagulation factors On the other hand, the decreased coagulability at 50 vol.% concentration was probably a dilutional effect.

A.285 Potato starch derived hydroxyethyl starch (200 000/0.5) compromises *in vitro* blood coagulation more than corn starch derived hydroxyethyl starch (200 000/0.5)

Marina Jamnicki, Andreas Zollinger, Burkhardt Seifert, Dragoljub Popovic, Thomas Pasch, Donat R Spahn. *Departments of Anaesthesiology and Biostatistics, University Hospital and University, CH-8091 Zurich, Switzerland*

Background & Goal of Study: Hydroxyethylstarch (HES) solutions were traditionally derived from corn starch. Recently, a new potato starch derived HES solution was developed. The goal of this study was to compare the effects of potato starch derived (pHES) and corn starch derived HES (cHES) on In vitro blood coagulation

Materials & Methods: With approval of the local ethics committee and written informed consent, 10 ml blood was collected from 80 surgical patients. Exclusion criteria were known coagulation disorders, renal and liver diseases and drugs interfering with blood coagulation. Blood samples were randomised to a 30% or 60% hemodilution group (30%HD, 60%HD) and subsequently diluted 30% and 60% in vitro with 0.9% saline, cHES 200'000/0.5 (HAES-steril® 6%, Fresenius Pharma, Stans, Switzerland) and pHES 200'000/0.5 (Infukoll® HES 6%, Serum-Werk Bernburg, Bernburg, Germany). Blood coagulation was assessed using thrombelastography (TEG) [1]. TEG tracings were analysed in terms of reaction time (r, normal = 12.0 + 2.3 mm), coagulation time (k, normal = 4.2 ± 1.6 mm), maximum amplitude (MA, normal = 63.5 ± 4.5 mm), angle α (α, normal = 60.2 ± 6.7°) and coagulation index (CI = −0.3258·r − 0.1886 k + 0.1224 MA + 0.0759 α − 7.7922, normal = 0 ± 2) [2] Parameters of hemodiluted blood were analysed using repeated measures analysis of variance with Greenhouse-Geisser correction P < 0.05 was considered statistically significant. Data are mean ± SEM

	Native	30% HD		60% HD	
		cHES	pHES	cHES	pHES
n	80	40	40	40	40
r	9.3 ± 0.7	10.4 ± 0.9	10.6 ± 1.0*	10.9 ± 0.7	12.2 ± 0.9*
k	3.5 ± 0.2	6.1 ± 0.4	6.7 ± 0.5*	14.4 ± 0.8	15.4 ± 0.8*
MA	67.6 ± 0.7	52.4 ± 1.1	51.6 ± 1.2*	36.8 ± 0.9	36.1 ± 0.9*
α	68.3 ± 1.0	56.0 ± 1.4	54.5 ± 1.7*	37.5 ± 1.1	34.7 ± 1.2*
CI	2.0 ± 0.4	−1.7 ± 0.5	−2.1 ± 0.6*	−6.7 ± 0.4	−7.6 ± 0.5*

*Significantly different ($p < 0.05$) from cHES during HD

Results: Hemodilution (HD) with both cHES and pHES compromised blood coagulation significantly Results are shown in the table

All values for cHES and pHES (except r at 30%HD) are significantly different from native. HD with pHES compromised blood coagulation significantly more than HD with cHES. This is evidenced by a greater increase of r and k and a more pronounced decrease in MA, α and CI during HD with pHES than with cHES

Conclusion: In vitro blood coagulation is more seriously compromised by potato starch derived HES than by corn starch derived HES

A.286 Preoperative hypervolaemic haemodilution with 6% low-molecular-weight hydroxyethyl starch: effect on some coagulation factors

R Cohendy, S. Kadri-Rozouki, J.-J Eledjam *Département d'Anesthésie-Réanimation, CHU de Nîmes, F30029 Nîmes, France*

Background and Goal: Preoperative haemodilution decreases transfusion requirement from major surgery[1] However the used dilutant might interfere with the activity of coagulation factors and thus increase the effect of their dilution The 6% LMW-HES Elohès™ did not depress factor VIII activity[2] and seemed safe for hypervolaemic haemodilution[3]. Therefore, this study described the effect on coagulation of Elohès™ used for acute hypervolaemic haemodilution in patients operated for colectomy under general anaesthesia (isoflurane/N_2O, fentanyl, vecuronium).

Methods: After induction of anaesthesia and measurement of CVP and invasive arterial pressure, Elohès was infused until the hematocrit (Ht) reached 30%

Arterial blood was sampled before and after dilution for blood gases (ABG), albumin ([alb]), Ht, coagulation studies: thrombin time (TT), APTT, Quick time and measurement of coagulation activity (Act) of. fibrinogen (I), prothrombin (II), factors VII, VIII, X The antigenic concentration ([Ag]) of these factors was also measured and related to Act to detect interference from Elohès

For this purpose, the ratios Act/[Ag] of each factor was calculated before and after dilution and compared using non-parametric tests. Results are given as· median [interquartile range].

Results & Discussion: Ten ASA 1 & 2 patients were studied. age = 58.5 [45; 66] yrs, BMI = 24.8 [21; 27] kg.m^{-2} Immediately preoperative Ht = 37.7 [35.6, 42.4]% and [Alb] = 37 [34.5; 41] g L^{-1}

The infusion of 11.9 [10; 13.6] mL kg^{-1} of Elohès™ gave

(a) Ht = 30.6 [28.5, 30.8] % [Alb] = 29 [26.5; 30] g.L^{-1}

(b) No modification in ABG, heart rate, mean arterial pressure but CVP increased +45 [20, 75]%

(c) TT, APTT, Quick time remained normal

(d) Parallel decrease in [Ag] of each factor and in [Alb]: −25 [−34.3, −19] %.

(e) Non significant and very small variations in Act/[Ag] of each factor (see table)·

Act/[Ag]	I	II	VII	VIII	X
Variation	−1.9	−1.5	0	−1.3	−2.2
%	[−5.5; 1.7]	[−2.4; 5]	[−2, 2.4]	[−13, 13]	[−2.4, 6.1]

Conclusion: Elohès infused for hypervolaemic haemodilution at approximatively 12 mL kg^{-1} did not have a direct effect on the activity of the studied coagulation factors.

A.287 Safety and tolerance of a novel formulation of hydroxyethyl starch (HES 130/0.4) in patients undergoing autologous blood donation with isovolaemic volume replacement

S.-M. Kasper, A. Strömich, U. Golla, J. Wixforth. *Department of Anaesthesiology, Universität zu Köln, Germany*

Background and Goal of Study: HES 130/0.4 is a novel formulation of hydroxyethyl starch with a mean molecular weight of 130,000 daltons and a molar substitution ratio ranging between 0.38 and 0.45 HES 130/0.4 has an intravascular half-life similar to that of current medium molecular weight hydroxyethyl starchs (HES 200/0.5) but is more rapidly and more completely excreted by the kidneys once the solution has left the intravascular space. We evaluated the safety and tolerance of HES 130/0 4 in the autologous blood donation setting HES 200/0.5 (HAES-SterilTM 6%, Fresenius, Bad Homburg, Germany) served as control

Materials and Methods: This was a single-center, controlled, randomized, double-blind, parallel-group, phase II clinical trial Sixty patients, ASA physical status class I–III, scheduled for elective surgery, were randomly assigned to receive, within 15 min and simultaneous to withdrawal of a unit (500 ml) of blood, an intravenous infusion of 500 ml of either HES 130/0 4 or HES 200/0.5. The concentration of either solution was 6 percent. Heart rate and blood pressure were measured oscillometrically before as well as 0, 30, and 60 min after blood donation. Blood samples for laboratory studies (haematology and clinical chemistry) were collected before and 60 min after donation and infusion of the study material. Patients were followed up for 24 h by means of a patient diary. Metric variables were compared by calculating 95% confidence intervals (CIs) for differences between groups Dichotomous variables were compared by Fisher's exact test. P < 0 05 was considered significant

Results and Discussion: There was no significant difference amongst the groups with respect to anthropometric data and medical history All patients completed the study according to protocol. No adverse events were observed during the monitoring period in the blood bank. At any time, heart rate, blood pressure, and laboratory data did not differ significantly between the HES 130/0.4-treated patients and their HES 200/0.5-treated controls (95% CIs included zero). The frequency and type of side effects (e g., dizziness, fatigue) recorded in the patient diaries (24 h after blood donation and infusion) were similar for both groups

Conclusion: Both HES 130/0.4 and HES 200/0.5 in a 1 1 volume ratio to blood loss effectively prevented hypotension (>20% decrease in systolic blood pressure from baseline) during and until 60 min after blood donation. Without intravenous volume replacement, such events may occur in as many as 50% of autologous blood donors (1) The tolerance of HES 130/0 4 was as good as that of HES 200/0 5 was

A.288 Factors involved in the perioperative adrenomedullary response to open heart surgery

I. Fidalgo, M T. García-Unzueta, C. Montalbán, M. Galindo, I. Del Moral, J Casanueva, M C Diago, J.R Berrazueta, J A Amado *Departments of Anesthesiology, Cardiology and Endocrinology University Hospital M. de Valdecilla. Santander, Spain*

Background & Goal of Study: Adrenomedullin (AM) is a recently identified vasodilating peptide Plasmatic AM levels are increased in different cardiovascular diseases (systemic or pulmonary arterial hypertension, heart failure, etc) We (1) and others (2) have demonstrated that AM increases during the perioperative period The aim of this study was to assess if basal hemodynamic parameters predict the AM response to open heart surgery

Material & Methods: We measured preoperative hemodynamic parameters and AM levels (RIA) in a group of 29 patients submitted to open heart surgery (14 valvular replacement, 10 coronary bypass and 5 valvular replacement plus coronary bypass) before the start of anesthesia, before the start of CPB, 20′ after the start of CPB, at the end of CPB, at the end of surgery, and 24 hours after the start of surgery Anesthesia was induced and maintained with sucesive doses of midazolam and fentanyl Muscle relaxation was achieved with vecuronium bromide

Results & Discussion: AM levels at the different times were 214 ± 287, 194 ± 286, 173 ± 206, 350 ± 367(*), 637 ± 711(*) and 618 ± 785(*) pg/ml, (*) p < 0 01, p < 00001, p < 0.0001 respectively, Friedman test followed by Wilcoxon test Basal AM levels were increased compared with a control healthy group Basal AM levels correlated significantly with systolic pulmonary pressure SPP (rs = 0.46 p = 0.013) and PCWP (rs = 0.44 p = 0 02), but not with other hemodynamic parameters When we compared those patients with ejection fraction (EF) < 40% with those >60%, AM levels were higher in the group with EF < 40 at the end of CPB and at the end of surgery (p < 0.03 and < 0 05 respectively).

Conclusions: Basal preoperative AM correlates with SPP and PCWP AM levels increase after the end of CPB, and the increase is higher in those patients with less EF.

A.289 Measurement and correction of ionized plasma magnesium during cardiopulmonary bypass

N.J Wilkes, T. Peachey, S.V. Mallett. *Department of Anaesthesia, Royal Free Hospital, London NW3 2QG, England*

Background and Goal of Study: Determination of plasma magnesium during and after cardiopulmonary bypass (CPB) is receiving increasing interest, not least because of the apparent association between hypomagnesaemia and cardiac arrhythmias (1). Magnesium (MgSO4) is frequently administered empirically to these patients The recent introduction of ion-selective electrodes (2) has facilitated serial measurement of ionised plasma magnesium [iMg2+] reflecting the active form of magnesium (3) The aim of our study was to determine levels of [iMg2+] in patients presenting for CPB and to correlate these with the dose of MgSO4 administered intraoperatively to maintain a normal or high [iMg2+] (ref range 0 54–0 67 mmol/l)

Materials and Methods: A pilot study involving 35 patients undergoing coronary artery bypass grafting (CABG) was performed [iMg2+] was determined using an ion-selective electrode (type Nova Biomedical) before, during (three samples) and after CPB When [iMg2+] was found to be low or declining steadily, MgSO4 10 mmol was administered intravenously

Results: 34 out of 35 patients displayed low [iMg2+] before initiation of CPB (mean 0 49 mmol/l, SD 0 03) Administration of MgSO4 10 mmol resulted in a mean rise of [iMg2+] by 0 24 mmol/l (SD 0.07) However, a continuous steady decline resumed and nine patients required a second dose of MgSO4 10 mmol The mean dose of MgSO4 administered was 12 6 mmol.

[iMg2+] M + SD	MgSO4 10 mmol	MgSO4 20 mmol
Pre CPB	0 49 ± 0 03	0 48 ± 0 03
During CPB, 1	0 70 ± 0 11	0 73 ± 0 11
During CPB, 2	0 70 ± 0 06	0 63 ± 0 07
During CPB, 3	0 66 ± 0 06	0.86 ± 0 18
Post CPB	0 59 ± 0 04	0 84 ± 0 13

Discussion: Our study demonstrated that a large proportion of patients presenting for CABG had abnormally low [IMg2+] These levels were corrected by the intravenous administration of MgSO4 10–20 mmol This may have implications for the prevention of postoperative cardiac arrhythmias

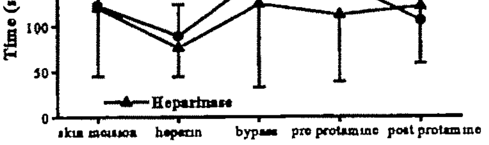
A.290 Heparinase reverses the inhibition of platelets by heparin in patients undergoing cardiopulmonary bypass

S.C. Kettner, S A. Kozek, C. Gonano, F.A. Seibt, O.P. Panzer, M Zimpfer. *Department of Anesthesiology and General Intensive Care, Ludwig Boltzmann Institute of Clinical Anesthesiology and Intensive Care, University of Vienna, Austria*

Introducton: Heparin, necessary for systemic anticoagulation during cardiopulmonary bypass (CPB), affects platelet function. Proaggregatory effects occur in 8.6%, mild to moderate inhibition in 58 6%, and severe inhibition in 32.8% of patients undergoing CPB (1). Protamine for reversal of heparin after CPB further worsens platelet function additionally, by causing thrombocytopenia and decreasing platelet aggregability (2) Heparinase, an enzyme isolated from *Flavobacterium heparinum,* is a possible alternative to protamine. In contrast to protamine heparinase seems to have minimal effects on platelets (3) The aim of the study was to test the hypothesis that heparinase is able to reverse inhibiting effects of heparin on platelet function, we measured platelet function in patients undergoing cardiac surgery

Methods: With local Ethics Committee approval and informed consent, 27 patients undergoing CPB were investigated. Patients were given 300 IU/kg of unfractionated heparin before aortic cannulation Heparin was neutralised by protamine in a ratio of 1.1 after CPB. Blood samples were



In vitro bleeding time (mean ± SD) *P < 0 05 native vs heparinase +P < 0.05 heparin vs bypass for native and P = 0 15 for heparinase obtained before skin incision, after heparin administration, 10 min after start of CPB, before and after protamine administration *In vitro* bleeding time was assessed by thrombostat (T 4000, VDG, Germany) measured with citrated whole blood without recalcification before and after incubation with heparinase Data were analyzed by ANOVA for repeated measurements followed by Scheffe test. Values as mean ± SD, $P < 0.05$ was considered significant

Results: Heparinase significantly decreased *in vitro* bleeding time in heparinised blood in patients undergoing CPB (figure).

Conclusion: Heparinase reverses adverse effects of heparin on platelets in *vitro*. It seems to be a promising potential alternative to protamine for the reversal of heparin anticoagulation

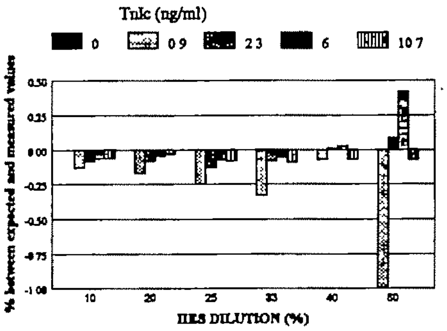
A.291 Hydroxyethyl starch slightly impairs measurement of troponin Ic concentrations: an *In vitro* study

G. Godet, S. Ben Ayed, M A Bernard, A. Kenzan, C. Huraux, E Kieffer, P. Coriat *Departments of Anaesthesiology, Biochemistry and Vascular Surgery, Pitié-Salpêtrière Hospital, Paris, France*

Introduction: Diagnosis of perioperative myocardial infarction is challenging, since there is no gold standard. Troponin Ic (TnIc) have been reported as a sensitive and specific marker of such a complication. However, abnormalities of TnIc measurement have been reported in patients receiving hydroxyethylstarches (HES). The aim of this in-vitro study was to analyze the effects of a step-by-step dilution of serum containing different TnIc levels with HES

Methods: Serum of patients with TnIc values of 0, 0.9, 2.3, 6.0, and 10.7 μg/ml was diluted by 10, 20, 25, 33, 40 and 80% with HES. Immunoenzymofluorometric assay on a Stratus autoanalyser (Dade) was used for the measurement of TnIc For each rate of dilution the ratio between the expected value (EV) and the measured value (MV) of TnIc was calculated.

Results: are reported in the figure.



For serum containing 2.3, 6.0, and 10.7 TnIc ng/ml, the decrease between EV and MV did not exceed 10% at each level of dilution less than 80% However a decrease by 12 to 30% was notified in the serum containing 0.9 ng/ml for all rate of dilution. Large discrepancy of TnIc measurement appeared only at unethical rate of dilution.

Discussion: TnIc determination using Dade assay remains reliable when serum of patients have been diluted with HES in an ethical manner The discrepancy of the measurement observed with 80% HES dilution may be explained by a matricial effect

A.292 White cell depletion of residual blood after normothermic CPB

M. Fox, S Coghlan, M. Jackson, B. Fabri. *The Cardiothoracic Centre, Liverpool, England*

Objective: To validate the report of Gu et al.[1] that leukocyte depletion of residual CPB blood prior to reinfusion significantly improves pulmonary gas exchange in the postoperative period.

Methods: A prospective randomised controlled study of 49 patients undergoing elective normothermic cardiac surgery was undertaken. After weaning from bypass the filter group (F) received residual blood via a leukocyte depleting filter RC400 (Pall). The control group (C) received unfiltered residual blood from the bypass circuit.

Results: The two groups were comparable with respect to pre and operative characteristics. There was no significant difference between groups F versus C in total WBC, neutrophil count, or volume of blood infused (1469 versus 1570 ml). Platelet and Lymphocyte counts were significantly reduced in group F after infusion of residual blood and at 24 hrs postop (Platelets: 154 preinfusion, 144 postinfusion ($p < 0$ 05) and 141 at 24 hours ($p < 0.05$); Lymphocytes 1.9 preinfusion, 1.11 postinfusion ($p < 0.05$) and 1.13 at 24 hrs ($p < 0.05$). The differences in Alveolar-arterial gradient were small and not significant. There were no difference in out-come measures F versus C of extubation time (145 v 178 mins), ICU stay (22 v 23 hrs), or hospital stay (7 5 v 8 days).

Conclusions: In contrast to hypothermic surgery, WBC depletion of residual bypass blood prior to reinfusion does not improve oxygenation after normothermic surgery.

A.293 Generation of elevated doses of bradykinin in retransfused pleural shed blood during extracorporeal circulation causes acute decrease of peripheral vascular resistance

F.S. Eckstein[1], H P Wendel[1], M.J. Jurmann[1], A.M. Scheule[1], L Haberle[2], G. Ziemer[1]. [1]*Dep. of Surgery, Div of Cardiac-, Thoracic- and Vascular Surgery;* [2]*Dep. of Anaesthesiology, University of Tubingen,*

Background: The contact of blood with artificial surfaces such as the components of the extracorporeal circulation during cardiopulmonary bypass (CPB) leads to an individual distinct systemic inflammatory response syndrome associated with the release of vasoactive mediators. The severe and acute decrease of arterial blood pressure (AP) specifically after retransfusion of pleural shed blood during cardiopulmonary bypass leads us to evaluate the influence of following pathways proposedly involved: complement activation by terminal complement complex (TCC), granulocyte activation by PMN-elastase, activation of the coagulatiuon system by thrombin-antithrombin III complex (TAT) and bradykinin, a powerful vasoactive mediator activated by kallikrein-kinin system.

Materials and Methods: Patients ($n = 13$, 58 ± 11 years) undergoing coronary artery bypass grafting including the use of the internal mammary artery (IMA). For IMA preparation pleura of the left hemithorax was opened. Blood accumulated within the pleural cavity during clamp-time was sucked into the CPB. With the aortic clamp still in place and with constant flow on the CPB (4 8 ± 0.4 l/min), mean AP and central venous pressure were on line monitored. Systemic blood samples were collected from all patients before retransfusion and after retransfusion immediately after the observed decrease in AP. An additional sample was taken out of the pleural shed blood before retransfusion

Results: Retransfused blood volume from the left hemithorax was 472 ± 258 ml. After 60 ± 15 s AP dropped from 68 ± 15 mmHg to 36 ± 8 mmHg ($p < 0$ 001) Calculated systemic vascular resistance (SVR) dropped from 1124 ± 263 dyn/s/cm^{-5} to 596 ± 153 dyn/s/cm^{-5} ($p < 0$ 001). To compensate the drop all patients had to be treated with bolus application of norepinephrine (2–6 μg) TAT in systemic blood samples increased after retransfusion from 23 2 ± 12 1 to 101 79 ± 44.6 ($p < 0$ 01) while TCC and PMN-elastase showed no significant differences. Bradykinin levels in the pleural shed blood was three times higher (45.4 ± 11 vs 121 2 ± 57, $p < 0.01$) than in both systemic blood samples

Conclusion: The observed drop in SVR after shed blood retransfusion during CPB may be explained by TAT-activation and transfused high bradykinin levels. Intraarterial transfusion of bradykinin in proven dosages mentioned above increases vascular permeability and is a potent vasodilator that acts through B2 kinin receptors to stimulate the release of endothelium-derived nitric oxide, prostacyclin, and hyperpolarizing factor (1). The granulocyte and complement pathways were not found to be activated Although this undesired drop in AP is easily counteracted by single shot injection of norepinephrine, accumulation of shed blood in the pleural cavity should be avoided by continous suction.

A.294 Trasylol exposure and re-exposure: histamine kinetics in patients undergoing cardiac surgery

M Adt[1], G Mayer[2], B Lamparter-Schummert[3], W Krack[4], W. Lorenz[4]. [1]*Sanatorium Mehrerau, Bregenz;* [2]*Bayer Leverkusen;* [3]*Deutsches Herzzentrum Berlin;* [4]*Universität Marburg, Germany*

Background: After re-exposure to trasylol (T), adverse reactions have been reported (1) They are commonly associated with a relevant increase of plasma histamine, PH. Therefore we took blood samples for determination of PH in 3 groups of patients (*pts*) undergoing cardiac surgery. pts with first T exposure n = 20, pts with T reexposure (Re-T), n = 18, pts receiving placebo = 0.9% saline solution (P), n = 19.

Materials and Methods: In all pts, anaesthetic manage-ment followed a standard protocol. Dosage of T was applied according to (1) Blood samples for PH determination were obtained, prepared (2) and deep-frozen at predefined time points (see table 1)

Results: Statistically relevant (threefold of pre-value) increased PH levels (1–2 ng/ml) occurred in all groups and at all time points observed in the study, whereas no clinical symptoms of anaphylaxis were reported

Table 1· time points of PH determination and incidence of statistically relevant histamine elevations

Groups	P	T	Re-T
Before test dose	–	0/20	0/18
5 min after test dose	1/19	2/20	1/18
5 min after sternotomy, before begin loading dose	3/19	3/20	2/18
5 min after begin loading dose	–	2/20	1/18
10 min after begin loading dose	1/19	1/20	2/18
20 min after begin loading dose	–	–	4/18

Conclusion: During cardiac surgery, a multitude of histamine liberating stimuli can entail repeated increases in PH concentration in pts with and without T including clinical symptoms (3). In this study, when T or P is administered, the incidence of statistically significant PH increase is about 5–15% in all groups, which is low compared to other phases of surgery. We conclude, that (1) there is no difference concerning histamine liberating potency between groups T, ReT and P; (2) our data suggest that cardiovascular reactions associated with high PH concentrations, especially to T reexposure, are not regularly to be expected; the underlying mechanism of these events may originate from special predisposing immunologic conditions of individual pts

This study was supported by a grant from Bayer Leverkusen.

A.295 Polymorphonuclear neutrophil functions and major oncological surgery

D. Mokart[1], D. Francon[1], J.P. Brun[1], J R. Delpero[2], G. Houvenaeghel[2], J.L. Blache[1]. [1]*Dpt of Anesthesia;* [2]*Surgery – Institut J. Paoli. I. Calmettes, 232 Bd, Ste Marguerite, 13273 Marseille cedex 9, France*

Introduction: PMN are important cell effectors of immune response. They are directly implied in host defences against micro organisms. Anesthesia and surgery induce complex modifications on PMN's functions some are activated and some are suppressed. This study was designed to observe perioperative PMN's functions after major oncologic surgery.

Methods: Ten cancer patients were studied during twelve days. They were operated for digestive cancer (n = 6) and gynecologic cancer (n = 4). A standardized anesthesia protocol and prophylactic regimen were used for all patients. Different parameters were studied by flow cytometric analysis: complement receptor (CD11b), FcγIII receptor (CD16), phagocytosis capacity, H_2O_2 production without and with stimulating agents (S aureus, PMA, FMLP). Spontaneous migration and chemotaxis were also studied. Blood samples were drawn just before surgery (D0) and at D1, D4, D7, D12 Thirty healthy patients was used as control group. Statistical analysis was made using anova, paired t test and unpaired t test.

Results and Discussion: Five patients developed post operative sepsis. Comparatively with control group, at D0 the patient's PMN were primed (↑CD16, ↑H_2O_2 Spont, ↑H_2O_2 Staph, ↑Phagocytose). Postoperatively this priming was potentiated (↑H_2O_2 Staph, ↑H_2O_2 PMA, ↑H_2O_2 Fmlp, ↑Phagocytose) and the PMN'S were spontaneously activated (↓CD16, ↓H_2O_2 Spont)

Expression of CD16, phagocytosis and production of H_2O_2 are expressed by Mean Fluorescence Intensity (MFI)

MCF	Control (n = 30)	Patients (n = 10)				
		D0	D1	D4	D7	D12
CD16	30	40 17^{+}	13 55*	28.14*	32.42*	34 07*
H_2O_2 (Spont)	3 5	6 03^{+}	17.22	11.24	9.99	11 61
H_2O_2 (Staph)	86	161.8^{+}	352 8*	343 90*	318 50*	329 11*
H_2O_2 (PMA)	240	235 6	498 00*	511 30*	526 00*	497.90*
H_2O_2 (Fmlp)	8.5	11 22	36.11*	33.53*	20 66	24 90*
Phagocytosis	4	6.36^{+}	9 16*	10 22*	9 28*	9 63*

$^{+}$ = $p < 0\ 05$ control versus D0, * = $p < 0\ 05$ D0 vs D1, D4, D7, D12

Conclusion: Perioperatively PMN's functions showed a proinflammatory status This status didn't protect against postoperative sepsis and could paradoxically induce it.

A.296 Effects of midazolam + nitrous oxide + oxygen anaesthesia and surgery on cellular immunofunction in mice

E. Dárdai, L. Dénes. *St. Stephen Hospital Department of Anaesthesia and Intensive Therapy, Budapest, Hungary*

Goal of Study: The perioperative immune dysfunction can be implicated in development of postoperative septic complication.

We therefore studied the influence of anasthetics alone and combined with surgery on cell mediated immunity in mice

Material and Methods: Twenty BALB/c female mice weighing 20–25 g were ventilated with Ayre T-piece, semi open system, modified for mice 5 animals were anaesthetized with midazolam i.v., 5 animals received N_2O 70% and O_2 30%, 5 animals received both of them, 5 animals served as control without anaesthesia. After 1 hour exposure with anaesthetics the animals were sacrified. An other 20 mice were anaesthetized with midazolam-N_2O-O_2 and operated on (total laparotomy). 5 animals served as control. 15 animals were sacrified after a period of 0.5, 1.0 and 2 0 hours anaesthesia and surgery (5 of each) At the end of anaesthesia arterial blood gas analyses were performed. The thymus, spleen and bone morrow T-lymphocyte subpopulations (CD3, CD4, CD8) were investigated by Fluorescence-Activated Cell Sorter.

Results: The number of helper (CD4) and suppressor (CD8) cells decreased significantly ($p < 0.05$) in thymus supernatant after 1 hour exposure of all anaesthetic combination The surgery and general anaesthesia expressed a highly significant ($p < 0\ 001$) time dependent immunosuppressive effects on CD4 and CD8 cell population in thymus and increasing number of CD3 cells after 0 5 hour In spleen and bone marrow significant changes were not observed in T-lmyphocytes.

Conclusion: The study clearly demontrates the immunosuppressive effects of intravenous and inhalational aneathestetics on T-lymphocyte subsets in mice. The surgery may have an additional unfavorable influence on cellular immunity. In immune compromised patients the post-injury immunosuppression can be responsible for increased number of septic complications.

Attempts have to be made to moderate the obligatory post-injury immunosuppression

A.297 Influence of cortisol inhibition on the response of IL-6 and IL-10 to surgery

M.A. Villanueva, C. Montalbán, M T García-Unzueta, I. Del Moral, J.J. López-Cordovilla, I. Fidalgo, J A. Amado. *Departments of Anesthesiology, Endocrinology and Nuclear Medicine, University Hospital M. Valdecilla, Santander, Spain*

Background & Goal of the Study: Over the past few years several studies have reported the relationship between interleukins and corticosteroids during surgery. Induction doses of etomidate transiently inhibit enzymes involved in cortisol synthesis. The aim of this study was to analyze if endogenous cortisol modifications cause variations on the response of Interleukins (Il-6 and Il-10) to surgical stress

Material & Methods: The study included 29 patients undergoing elective abdominal surgery randomly divided into two groups. Group 1 (n = 14) received thiopental 4–6 $mg.kg^{-1}$ as anaesthesia inducing agent and group 2 (n = 15) recived etomidate 0 3–0.5 $mg.kg^{-1}$ Blood samples were collected before anesthesia induction (T1), just before incision (T2), 2 hours (T3), 4 hours (T4), 6 hours (T5), 12 hours (T6), 24 hours (T7), and 48 hours (T8) after the induction of anesthesia. Interleukin 6 and 10 were measured in plasma samples by ELISA and cortisol was determinated by radioimmunoassay. Results are expressed as mean ± SD. Statistical comparisons between groups were analysed by MannWhitney test using SPSS for Windows.

Results & Discussion: There were no statistical differences in basal patient data or surgical procedures between the two groups. The release of cortisol was strongly inhibited at T3, T4, and T5, in group 2. IL-6 blood level in group 2 was significantly higher than in group 1 at T5 (194.9 ± 175.6 pg/mL vs 89.45 ± 60.52 pg/mL) IL-10 was higher in thiopental group than in etomidate group at T4 (22 ± 20 pg/mL vs 7.3 ± 4.9 pg/mL)

Conclusions: The differences in IL-6 and IL-10 between both groups suggest that cortisol modulates the release of these cytokines

A.299 Effects of pure propofol, Diprivan® and Intralipid on active oxygen species produced by activated polymorphonuclear neutrophils

P Hans, M. Mathy-Hattert, G. Deby, C. Deby, M. Lamy. *Centre for the Biochemistry of Oxygen, University of Liege & Department of Anesthesia and Intensive Care Medicine, Hopital de la Citadelle, CHU Liege, Belgium*

Background & Goal of Study: Active oxygen species (AOS) produced by activated polymorphonuclear neutrophils (PMN) are involved in tissue injury associated with many acute inflammatory processes. This study was designed to investigate the effects of pure propofol (PPF), a well known antioxidant agent, of its commercial formulation Diprivan® (DI), and of its vehicle solution Intralipid (IL), on AOS produced by activated PMN, using luminol-enhanced chemiluminescence (CL).

Methods: Human PMN were isolated from blood by density gradient centrifugation, counted and suspended in phosphate-buffered saline. Pure PPF dissolved in carbitol, DI and IL were added at various concentrations to PMN batches ($5\ 10^5$ cells) activated by phorbol myristate acetate (PMA) 10^{-6} M, in presence of luminol 10^{-4} M. CL was measured using a Bio-Orbit 1251 Luminometer. Results were expressed as the percentage of inhibition of control value (CL measured in the absence of drug) Linear correlation was fitted by the Pearson's test.

Results: The CL inhibition of activated PMN by DI (PPF in IL) and IL alone was variable, depending on cell batches (table 1). This inhibition was similar for both drugs and not directly related to DI or IL concentrations The CL inhibition by pure PPF was dose-dependent in the range of $5\ 10^{-5}$ to 10^{-3} M and linearly correlated with the log values of the drug concentration ($r = 0.96$; $P < 0.0001$).

Table CL inhibition of 10^{-6} M PMA activated PMN by DI (PPF in IL) at various concentrations, and by IL alone The effects of DI are expressed by the first number in each column and those of IL by the second number in each column

PMN Batches	CL inhibition (%) Diprivan® (μM of PPF)/IL (volume in μl)			
	10/0.09	100/0.9	300/2.7	1000/9
1	0/22	84/73	97/96	98/95
2	0/0	39/35	52/47	53/47
3	25/47	24/19	68/61	71/57
4	–	76/75	70/73	84/82

Discussion: The results of this study showed an unexpected inhibiting effect of IL on PMN CL, interfering with the antioxidant property of pure PPF. When tested in the absence of IL, PPF demonstrated a dose-dependent antioxidant activity against AOS, already observed at clinically relevant concentrations The potential applications of these results in pathologies involving AOS deserve further investigations.

A.300 Cellular mechanisms underlying inhibitory effect of halothane on inducible nitric oxide synthase induction evoked by interleukin-1β

H Maeda, M. Ymamamoto, K. Mizumoto, K. Ogawa, H. Iranami, Y. Hatano *Department of Anesthesia, Wakayama Medical College, Wakayama, Japan*

Background: We have previously reported that halothane (HAL) inhibits interleukin-1β (IL-1β)-stimulated induction of inducible NO synthase (iNOS) in rat aorta[1]. However, the exact site of action of HAL is still unclear. Accordingly, the present study was aimed to elucidate the mechanisms underlying inhibitory effect of HAL on iNOS induction evoked by IL-1β.

Methods: With institutional approval, rings without endothelium from isolated rat thoracic aorta were used.

(1) Effect of HAL on iNOS mRNA expression induced by IL-1β; Rings were exposed for 5 h to (1) IL-1β (20 ng/ml) or to (2) IL-1β+ HAL (3MAC) After exposure, the iNOS mRNA expressions were measured by Northern blot analysis.

(2) Effect of HAL on GTP:cyclohydrolase (GTP.CH) ~ tetrahydrobiopterin (BH4) pathway, GTP CH is a stimulator for induction of BH4 which is an essential cofactor of iNOS activation. Contractile response to phenylephrine (PE, $10^{-9} \sim 10^{-5}$ M) was tested in each ring. After 5 h exposure to (1) IL-1β (20 ng/ml), (2) IL-1β (20 ng/ml) + a GTP:CH inhibitor, 2, 4-diamino-6-hydroxypyrimidine (DAHP, 3×10^{-3} M), (3) IL-1β (20 ng/ml) + DAHP (3×10^{-3} M) + HAL (4 MAC) or (4) IL-1β (20 ng/ml) + HAL (4 MAC), the rings were washed with fresh fluid for 30 min, then a second contractile response to PE ($10^{-9} \sim 10^{-5}$ M) was obtained, followed by the addition of N^G-nitro-L-arginine (LNA 3×10^{-5} M) Contraction was expressed as percentage relative to that induced by first response to PE (10^{-5} M).

Data were expressed as mean ± SEM, and analyzed statistically by ANOVA and unpaired Student's t test. Differences at $p < 0.05$ were considered significant.

Results: IL-1β induced iNOS mRNA expression in rat aorta was not affected significantly by HAL (3MAC). Exposure to IL-1β inhibited the contractile response of rings to PE The addition of LNA (3×10^{-5} M) completely restored the contraction which had been inhibited by IL-1β exposure. HAL (4MAC) reversed IL-1β-induced inhibition significantly. Treatment with DAHP partially reversed the IL-1β-induced inhibition of the contractile response to PE Simultaneous treatment with HAL and DAHP further reversed IL-1β-induced inhibition.

Conclusion: The present study demonstrated, that 1) HAL did not affect IL-1β induced iNOS mRNA expression, 2) DAHP partially reverses IL-1β-induced inhibition, suggesting that the GTP:CH-BH4 pathway plays a role as cofactor for IL-1β-evoked NO production in VSM tissue and 3) HAL further reversed IL-1β-induced hyporeactivity in the presence of inhibition of GTP:CH-BH4 pathway. These findings suggest that the main site of inhibitory action of HAL on iNOS induction evoked by IL-1β lies in the post-transcription process.

A.301 Leucocyte alterations during hyperthermia

O. Ahlers[1], T. Boehnke[1], T. Kerner[1], M. Deja[1], D Keh[1], J Löffel[2], B. Hildebrandt[2], H. Riess[2], P Wust[3], D Pappert[1], H Gerlach[1]. [1]*Abt. f. Anästhesiologie und operat Intensivmedizin;* [2]*Abteilung für Hämatologie/Onkologie;* [3]*Strahlenklinik und -poliklinik, Virchow-Charité, Humboldt-Universität, 13344 Berlin, Deutschland*

Background: Leukocyte alterations are determined under several clinical conditions, accompanied with increased body temperatures – e.g during activation of immune system Our aim was to examine the influence of isolated hyperthermia on leukocytes in patients without infections. Therefore we obtained blood from patients with metastatic colorectal carcinoma during induced whole body hyperthermia of 42°C, caused by infrared-A-irradiation. This is used as part of systemic Cancer Multistep Therapy (sCMT), which was started as a phase I/II clinical study

Materials and Methods: Blood samples were obtained before the beginning of the therapy at 37°C (T1), at 40°C (T2), at the end of the plateau of 42°C (T3) and after therapy at 37°C again (T4). Time between investigations was about 2 hours. Examined cells were PMN, lymphocytes and monocytes. In addition, HLA-DR on monocytes as well as L-Selectin on PMN and monocytes were analysed Leukocytes were counted by Cell Dyn 1600® (Abbott), subpopulations and surface markers were investigated by flow-cytometry (FACScan®, Becton Dickinson). Data were compared by using a Wilcoxon rank sum test Significance was defined by $p < 0.05$

Results: Leukocyte subpopulations showed different courses. Percentage of PMN increased significantly under hyperthermia, whereas percentage of lymphocytes and monocytes decreased significantly Absolute cell counts showed similar developments: Number of PMN stayed constant until T3 and increased at T4, whereas number of monocytes and lymphocytes decreased until T3 with a slight tendency back to the starting values at T4. Result was a slight decrease of leukocytes before T3 and a significant increase at T4. HLA-DR and L-Selectin expression on monocytes increased slightly while L-Selectin expression on PMN stayed constant.

Conclusions: Hyperthermia up to 42°C induces significant changes in leukocyte subpopulations. The increase of total leukocytes and PMN-fraction seems to be first (until T3) compensated by substitution of liquids because of the high temperatures At T4 (37°C again), we found increased, but not stimulated granulocytes (constant L-Selectin expression). The decreased number of monocytes seems to be slightly activated, the decreased number of lymphocytes needs to be analysed for changes in subpopulations Further investigations about these results are necessary.

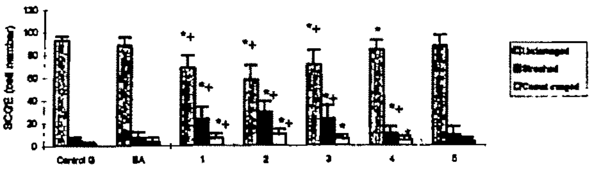
A.302 Use of single cell gel electrophoresis technique to detect DNA damage in lymphocytes of patients anaesthetized with isoflurane

L. Karabiyik[1], N Aygun[2], S. Şardaş[2]. [1]*Department of Anaesthesia, Turkish State Railways Hospital, Ankara;* [2]*Department of Toxicology, Gazi University, Faculty of Pharmacy, Ankara, Turkey*

Background & Goal of Study: Although the mutagenic effect of isoflurane is well documented in occupational exposure, its mutagenic effects in patients are not well known[1,2] In this study, the DNA damage were evaluated in lymphocytes of patients exposed to clinical concentrations of isoflurane, using Single Cell Gel Electrophoresis (SCGE) technique.

Material & Methods: ASA I–II 12 adult unpremedicated patients who were undergoing elective surgery and 11 adult control subjects were included in this study. Anaesthesia was induced with thiopentone 6 mg kg^{-1} and fentanyl 1 mg. Vecuronium 0.1 mg kg^{-1} was also given for neuromuscular block. Anaesthesia was maintained with isoflurane 1–1.5% in oxygen Venous blood samples were taken before anaesthesia, at 60. min, 120. min during anaesthesia, postoperative first, third and fifth days. SCGE (Alkaline Comet Assay): Lymphocytes were separated from blood samples and mixed with agarose. Electrophoresis was carried out 40 min at 19 V, 300 mA. Each slide was stained with ethidiumbromide. 100 cells per subject were analyzed under a fluorescent microscope such as undamaged, streched and comet imaged cells. Results were analysed by Student's T, Mann-Whitney U, paired T and Wilcoxon tests

Results & Discussion: A significant increase in the number of streches and comets were observed in the lymphocytes of patients as compared to before anaesthesia and to control at 60. and 120 min during anaesthesia ($p < 0.05$). Increase in DNA damage decreased during postop. period and returned to control and initial values at postop fifth day (figure)



* $p < 0.05$ (with control Group), + $p < 0.05$ (with BA), BA Before Anaesthesia, 1 60 min, 2 120 min, 3 Postop. third day, 5 Postop fifth day

Conclusion: This study supports the existence of an association between reversible DNA damage and anaesthesia with isoflurane by SCGE technique

A.303 *In vivo* and *in vitro* effects of propofol, midazolam and fentanyl on natural killer cell cytotoxicity

D Işık, Z. Eti, F Tukenmez, F.Y. Göğüş, M. Başaran. *Marmara University Medical Faculty, Anaesthesiology and Reanimation Department, Istanbul, Turkey*

Background & Goal of Study: The aim of this study was to evaluate in vivo and in vitro effects of propofol, midazolam and fentanyl on natural killer (NK) cell cytotoxicity.

Materials & Methods: After approval from Faculty Ethics Committee and written informed consent from patients; 8 patients scheduled for laparoscopic cholecystectomy, ASA I-II and aged 20–50 years were randomly assigned into two groups (n = 4). In the I. group after the induction with propofol 2 mg/kg and fentanyl 5 μg/kg i.v. anaesthesia was maintained with the infusion of propofol 10–6 mg/kg/h and fentanyl 3 μg/kg/h In the II. group after induction with midazolam 0.2 mg/kg and fentanyl 5 μg/kg i.v. anaesthesia was maintained with the infusion of midazolam 0.15 mg/kg/h and fentanyl 3 μg/kg/h. Peripheral blood samples were collected before induction, 60 minutes after induction and 60 minutes after the end of anaesthesia. In vitro used concentration of drugs were as propofol 10 μg/ml, midazolam 400 ng/ml and fentanyl 10 ng/ml. Radioactive labeled K-562 cells were used as target cells. NK cytotoxicity was calculated with the formula;

% = Cpm (test) – Cpm (med)/Cpm (max) – Cpm (med)

Results and Discussion: Before induction, 60 min. after induction and 60 min. after the end of anaesthesia in vivo NK cytotoxicity of patients anesthetized with propofol and fentanyl were %48.75 ± 14.6, %45 25 ± 13.86, %43.6 ± 13.89 respectively. In vitro values were %47.75 ± 19.19 with propofol, %46 ± 18 45 with fentanyl and %47 ± 16 24 with propofol and fentanyl. In vivo values in the II. group were %63.5 ± 16.8, %58.25 ± 15.56 and %62 ± 20.8 respectively. In vitro values were; %61.25 ± 16.25 with midazolam, %61 25 ± 17 65 with fentanyl and %62 25 ± 16.78 with midazolam and fentanyl There was no significant difference between and in the groups.

Conclusion: When used in clinically relevant concentrations, propofol, midazolam and fentanyl had no supressive effect on NK cell cytotoxicity even in vivo or in vitro.

A.304 Activation of the complement system during autologous blood transfusion: an *in vitro* study with different autotransfusion devices

M. Tylman, A. Bengtsson, J.P. Bengtson, H. Haljamäe. *Department of Anaesthesiology and Intensive Care, Sahlgrenska University Hospital, Göteborg, Sweden*

Background: A number of autotransfusion devices are commercially available. It has previously been shown that the complement system is activated in shed blood during orthopaedic surgery. The aim of the present study was to determine whether autotransfusion devices lead to complement activation during processing and whether activation initiates throught the classical or the alternative pathway.

Methods: Three different autotransfusion systems were investigated: AT200™ (Hematec, Lund, Sweden), C.A T.S^R (Continuous Autotransfusion System, Fresenius, Germany) and Cell Saver^R (Haemonetics, Braintree, USA) To simulate the degree of complement activation in wound blood, bank blood was activated by CVF (Cobra Venom Factor) in a concentration of 0 2 U/ml during 60 minutes and at 37°C. Activation with CVF was performed in 24 blood bags, eight in each group. After incubation with CVF the blood was processed by the different devices. The experiment was repeated, proceeding exactly as stated above but this time without any CVF activation. The samples were collected from the blood bag, the processed blood and the waste bag. The complement components. SC5b-9 (TCC), C3a and Bb, C4d fragments (Quidel, USA), were determined by an enzyme immune assay (EIA) method.

Results: The concentrations of SC5b-9, C3a and Bb, C4d fragments in processed blood and in the waste bag from C A.T S^R and Cell Saver^R were significantly lower than in the whole blood ($p < 0.01$) in experiments with and without CVF activation Higher concentrations of C3a, SC5b-9 and Bb fragment were found in the study with CVF activation in processed blood from the AT200™ system compared to C.A.T.S^R($p < 0.01$) or Cell Saver^R ($p < 0.01$) The concentration of complement components were decreased in the ultrafiltrate (waste bag) from the AT200™ system compared to the whole blood ($p < 0.05$).

Conclusion: The study shows that the main part of activation occurs in the wound. The activation of the complement cascade goes throught the alternative pathway.

A.305 Arterial blood gases during shivering and after treatment with meperidine, oxygen or both

Getúlio R. de Oliveira Filho, Luiz C Utzig, Saul F Linhares. *Department of Anaesthesiology, Hospital Governador Celso Ramos, Florianópolis, SC, Brazil*

Background & Goal of Study: Postanaesthetic shivering (PAS) causes substantial increase of oxygen consumption with resulting hypoxaemia and metabolic acidosis(1). Meperidine is effective in abolishing PAS(2) This study evaluated whether meperidine could cause hypercarbia and respiratory acidosis when used to treat PAS

Materials & Methods: With IRB approval, forty patients (18 to 65 years old), both sexes, exhibiting shivering in the PACU, were randomly assigned to 4 treatment Groups (n = 10, each): S – saline 3 ml i v., M – meperidine 30 mg i.v., SO – saline 3 ml i.v. plus oxygen 3 L.min^{-1} via nasal catheter, or MO – meperidine 30 mg i.v plus oxygen, as above. Shivering was graded in a four point scale. Room temperature was kept at 26.01 ± 0.8°C. Shivering scores, axillary temperature, heart rate (HR), blood pressure and arterial gases were measured at M0 – during shivering, and at M1 – 15 minutes after treatment. Two-way ANOVA and chi-square were used for between and within groups comparisons.

Results and Discussion: Values are mean ± SD. Meperidine abolished PAS in 100% of patients. At M1, shivering was still present in 70 and 80% of patients in groups S and SO, respectively Blood pressure and respiratory rate did not change at M1 in any group. HR decreased significantly only in Group MO, at M1 Non significant alterations were observed after treatment in axillary temperature (°C) (from 35.8 ± 0.65 to 35.92 ± 0 63, from 36 63 ± 0.59 to 36.18 ± 0 63, from 35 74 ± 0.46 to 35 98 ± 0.43, from 35 41 ± 0.36 to 35 08 ± 0.55), pH (from 7.34 ± 0 04 to 7.4 ± 0 19, from 7.35 ± 0.05 to 7.36 ± 0.06, from 7.34 ± 0.04 to 7.32 ± 0 05, from 7 31 ± 0.07 to 7.31 ± 0.04) or $PaCO^2$ (mmHg) (from 36 63 ± 7.79 to 35.97 ± 8.04, from 30.77 ± 5.77 to 32.08 ± 6 16, from 31.49 ± 4 67 to 34.43 ± 4.56, from 35.07 ± 6.25 to 34.61 ± 8.36), in Groups S, SO, M and MO, respectively Base excess (mEq L^{-1}) did not changed significantly after treatment (from −7.53 ± 3.25 to −6.19 ± 4 23, from −7 77 ± 2.36 to −7 42 ± 2.37, from −7.35 ± 4 23 to −7.37 ± 3 35), in Groups SO, M and MO, but increased significantly in Group S (from −8.88 ± 3.24 to −6.91 ± 3.44). PaO_2 (mmHg) increased significantly in Groups SO and MO at M1 (from 88.05 ± 8.28 to 151.38 ± 31 09 and from 79.77 ± 11.24 to 145 37 ± 26.45) but did not change in Groups S and M (from 79.12 ± 13.72 to 79.41 ± 12.79 and from 87.73 ± 13.34 to 83.71 ± 18.02) SaO_2 (%) also increased significantly in Groups SO and MO (from 94.66 ± 1.53 to 98 ± 0.51 and from 92.55 ± 2.27 to 98 1 ± 0.61) and did not change in Groups S and M (from 91.48 ± 3.89 to 92.46 ± 3.04 and from 93.66 ± 4.33 to 93.69 ± 3.53).

Conclusions: Meperidine (30 mg) abolishes shivering, without causing hypercarbia or affecting axillary temperature, base excess, SaO_2 and PaO_2. Oxygen supplementation must be used as part of the treatment of postanaesthetic shivering

A.306 Xenon does not trigger malignant hyperthermia in malignant hyperthermia-susceptible pigs

G Froeba, R.J. Pazhur, C. Baur, M. Georgieff, T. Marx. *Department of Anaesthesiology, University of Ulm, D-89075 Ulm, Germany*

Background: Since 1951 the inert gas Xenon has been known to have excellent anaesthetic properties. In contrast to Nitrous Oxide no fetotoxicity has been reported (1). The possible triggering of Malignant Hyperthermia (MH) under condition of Xenon anaesthesia has not yet been investigated

Material: After approval by the institutional animal ethics comittee 12 MH-susceptible pigs (Pietrain) were anaesthesid with pentobarbital and buprenorphine. An arterial line (a femoralis), a Swan-Ganz catheter and a venous line (v. femoralis) were placed under these anaesthetic conditions. After a recovery period of 60 min, Xenon anaesthesia (70% inspired) started for 2 hours During that time, heartrate, mean arterial pressure, cardiac output and body temperature were measured every 10 minutes, venous-, mixed-venous-, arterial-blood gases and catecholamines were collected at the same measuring points. After a washout period of 30 min. Halothane exposure started (1% inspired). Within 15 min. an additional bolus of Succinylcholine (3 mg/kg) was adminestered and the investigation was proceeded with the same protocol.

Results: During Xenon anaesthesia no haemodynamic or metabolic changes occurred, indicating the triggering of MH.

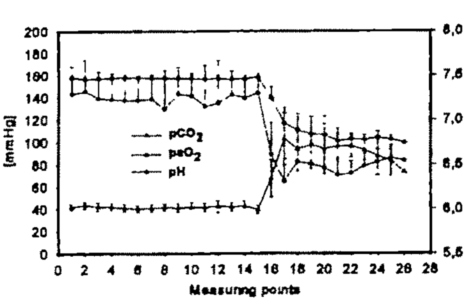

Fig. 1. Arterial Blood Gases, Measuring points 1–13 Xenon anaesthesia, 14–26 Halothane and Succinylcholine

After administration of Halothane and Succinylcholine haemodynamic and metabolic changes, typical for MH, occurred within 10 min. (Fig 1).

Conclusion: Xenon does not trigger MH in MHS-pigs.

A.307 Central-core-like structures in a family disposed to malignant hyperthermia

R Fricker[1], R.E. Bittner[2], H.G. Kress[1] [1]*Dept. of Anaesthesiology & Intensive Care B;* [2]*Dept. of Anatomy, Univ. of Vienna, Vienna, Austria*

Background and Goal of the Study: Following a fatal MH crisis of a 22 years old man 79 members of his family pedigree were contacted. Until now 31 out of 79 individuals followed our recommendation to undergo an in vitro contracture test (IVCT) 19 of these 31 IVCT tested members also underwent a detailed histomorphological investigation of their skeletal muscle specimens which showed morphological changes similiar to previously described central-core-like structures (CCLS) (1). Goal of the study was to look for a possible correlation between IVCT results and histomorphological changes in the skeletal muscle of the respective family members.

Material and Methods: Between 1980 and 1997 31 members of a MH suspected family were IVCT tested using halothane and caffeine according to the European MH protocol (2) Beginning with the year 1995 in 19 out of 31 individuals also muscle specimens were examined using light and electronmicroscopic methods. This examination was done by an independent investigator unaware of the IVCT diagnoses.

Results and Discussion: Out of the 31 IVCT tested patients 12 (6 female/6 male) had a MHS (MH susceptible), 10 (4 female/6 male) a MHE (MH equivocal) and 9 (8 female/1 male) a MHN (MH negative) diagnosis. 11 out of a total of 19 histomorphologically investigated family members showed CCLS. All 11 CCLS positive individuals were also MH positive in the IVCT (6 MHS: 3 female/3 male, 5 MHE. 3 female/2 male). All 8 CCLS negative probands were tested as MH negative in the IVCT.

Conclusion: 11 members of a MH disposed family revealed striking histomorphological changes described as CCLS. In every case the structures were associated with a MHS or MHE diagnosis and were never seen in a MHN individual of this family. Since so far susceptibility to MH is not believed to be diagnosed by histomorphological changes, a separate morphological entity associated with the occurrence of MH is suggested. Genetic work to confirm this hypothesis is already in progress.

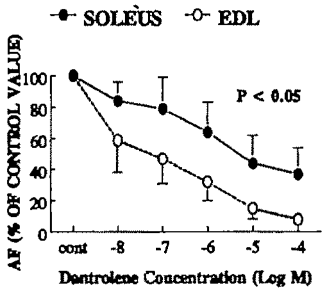
A.308 Effects of dantrolene on rat fast (extensor digitorum longus) and slow (soleus) skeletal muscles

O. Langeron, S Fratea, G. Orliaguet, C. Coirault, P. Conat, B. Riou
Department of Anaesthesiology, University Hospital of Pitié-Salpêtrè, Paris, France

Background and Goal of Study: Dantrolene acts on sarcoplasmic reticulum function of skeletal muscle, inducing a marked negative inotropic effect The aim of this study was to compared the effects of dantrolene on fast (extensor digitorum longus = EDL) and slow (soleus = SOL) muscles in rat

Materials and Methods: The effects of D (10^{-8} to 10^{-4} M) were studied in rat muscle strips from EDL (n = 8) and SOL (n = 8) *in vitro* (Krebs-Henseleit solution, 29 °C, pH 7 40, Ca^{++} 2 5 mM) in the tetanus mode (50 Hz, stimulation frequency 10/min) The active isometric force (AF) was measured. Data are % of control values ± SD. Statistical analysis was performed by repeated-measure analysis of variance and Newman-Keul's test

Results and Discussion: AF was markedly decreased in both groups (maximum decrease in AF 37 ± 17 and 8 ± 4% of control values at 10^{-4} M in SOL and EDL groups respectively), and the negative inotropic effect was significantly greater in EDL group as compared to SOL group (figure).



Conclusion: In our study, dantrolene induced a significant negative inotropic effect both in fast (EDL) and slow (SOL) rat skeletal muscles, with a significant more pronounced effect in fast muscle suggesting a difference in the magnitude of action of dantrolene on these two types of skeletal muscles.

A.309 Secretion of I.v. dantrolene into breast milk after MH therapy

R. Fricker, K. Hörauf, P. Felleiter, H.G. Kress. *Dept. of Anaesthesiology & Intensive Care B Univ of Vienna, Vienna, Austria*

Introduction: Dantrolene is widely accepted as first line treatment of malignant hyperthermia (MH) crisis (1). Although it has been presumed that dantrolene may cross into breast milk (2), until now no data have been published.

Case Report: We now report the case of a 37 years old woman (62 kg body weight) who developed symptoms of MH (tachycardia, respiratory acidosis, hyperkalaemia, hyperthermia) during general anaesthesia for caesarean section As a developing MH crisis was suspected, a bolus of 160 mg dantrolene was given intravenously and dantrolene therapy was continued over 3 days (560 mg/1 day, 320 mg/2.day, 80 mg/3 day)

Methods: From the 2.–4. postoperative day dantrolene levels in her breast milk were assessed by HPLC-technique (detection limit: 0 02 µg/ml).

Results: Dantrolene was detected in decreasing concentrations (conc.):

Hours after first I v. application	Breastmilk conc (µg/ml)
36 hrs	1 2
43 hrs	0 9
56 hrs	0 55
61 hrs	0 45
66 hrs	0 20
76 5 hrs	0 08
83 5 hrs	0.05

Halflife of dantrolene in the breast milk was estimated by log-linear fitting of the terminal elimination phase. It was calculated to be 9 02 hours

Conclusion: Dantrolene administered intravenously enters breast milk. However, the concentrations found in the patient were unlikely to produce severe side effects in a breastfed newborn. Thus, at least 3 days after dantrolene administration breast milk feeding can be allowed.

A.310 Perianaesthetic hyperglycaemic and endocrine responses to open cholecystectomy: comparison of general and combined general plus epidural anaesthesia

Getúlio R. de Oliveira Filho, Eliane Cidral, Mahmud K. Zardeh, Eugênio Maier *Department of Anaesthesiology, University Hospital – UFSC, Florianópolis, SC, Brazil*

Background & Goal of Study: Epidural anaesthesia can attenuate stress responses to surgery$^{(1)}$. Perioperative glucose, ACTH, cortisol and ADH responses were compared between general (G) and combined general plus thoracic epidural (GE) anaesthesia for cholecystectomies.

Materials & Methods: With IRB approval, 24 ASA I or II consenting adults were randomly assigned to Group G (n = 15) and Group GE (n = 9). General anaesthesia included propofol, alfentanyl, isoflurane and vecuronium Group GE received thoracic epidurals up to T4 with 0 5% bupivacaine prior to general anaesthesia. Venous blood was collected for glucose, ACTH, cortisol and ADH measurements at: M0 – baseline, M1 – before skin incision, M2 – after opening of peritoneum, M3 – during dissection of the gall bladder, M4 – during closure of the peritoneum, M5 – before tracheal extubation, and M6 – 20 minutes after recovery. Log-transformed data were treated by two-way, repeated measures ANOVA followed by *post hoc* tests ($\alpha = 0$ 05).

Results & Discussion: Glucose and cortisol increased in Group G from M3 to M6. In Group GE, glucose increased from M2 to M5, but was lower than in Group G at M5 and M6. ACTH did not change in any group. Cortisol did not change in Group GE, and its levels were lower than in Group G at M3, M5 and M6. ADH increased from M2 to M6 in Group G, with no changes in Group GE. (Table I)

Table. Hormonal responses (rounded values, mean ± SD)

	M0	M1	M2	M3
Glucose G	110 ± 40	112 ± 29	110 ± 30	137 ± 36*
GE	94 ± 16	130 ± 24*	131 ± 25*	129 ± 26*
ACTH G	50 ± 27	48 ± 21	57 ± 30	66 ± 29
GE	53 ± 36	55 ± 24	62 ± 37	65 ± 25
Cortisol G	330 ± 191	381 ± 181	740 ± 134	984 ± 960*#
GE	465 ± 136#	399 ± 224	369 ± 223	401 ± 215
ADH G	3 ± 5	2 ± 2	9 ± 11*	21 ± 27*
GE	6 ± 8	3 ± 1	3 ± 18	± 7

	M4	M5	M6
Glucose G	151 ± 41*	153 ± 41*	165 ± 42*
GE	130 ± 32*	120 ± 39*#	107 ± 27#
ACTH G	79 ± 40	72 ± 60	58 ± 39
GE	57 ± 30	48 ± 19	54 ± 25
Cortisol G	1046 ± 739*	1013 ± 539*	1005 ± 483*
GE	505 ± 232	477 ± 182#	543 ± 132#
ADH G	22 ± 20*	10 ± 10*	10 ± 8*
GE	8 ± 8	8 ± 8	7 ± 5

Units Glucose = mg dL^{-1}, ACTH, ADH = pg mL^{-1}, Cortisol = μg mL^{-1} * = $p < 0$ 05 compared to M0, # = $p < 0$ 05 between groups

Conclusion: Combined general plus thoracic epidural anaesthesia attenuates perianaesthetic hyperglycaemic and endocrine stress responses to open cholecystectomy.

A.311 Metabolic acidosis and respiratory acidosis impair gastroduodenal motility in a pig model

J.P. Tournadre[1], C H. Malbert[2], P. Boulétreau[1], D Chassard[1]
[1]*Anesthésie, Hôtel-Dieu, 69002, Lyon;* [2]*Institut National pour la Recherche Agronomique Saint-Gilles, Rennes, France*

Background: Acidosis is thought to impair smooth muscle function in various organs (1) However, the effects of acidosis on the gastro-duodenal tract are unknown while its dysfunction has potential perioperative harmful consequences (2) The aim of this study was to evaluate the effects of metabolic (MA) and respiratory acidosis (RA) on upper gut motility A pig model, where gut motility is respected (3), was choisen for this purpose.

Methods: Anesthesia was induced with halothane and maintained with α-chloralose-urethane administration (iv) in 5 intubated-ventilated pigs Increased dead space and perfusion of hydrochloric acid 1 N (150 ml over 30 min) were used to induce RA and MA respectively During these events, measurements of fundic tone using an electronic barostat, antro-pyloro-duodenal phasic motility with perfused manometry and antro-duodenal electric control activity by electromyography were used to evaluate gastro-duodenal function. Statistical significance was determined using ANOVA analysis Results are mean ± SD

Results: The acid infusion decreased pH from 7.41 ± 0 03 to 7.25 ± 0 03 ($P < 0$ 02) without significant change for $PaCO_2$ values (39 7 ± 3 8 mmHg at baseline and 44.4 ± 1.3 mmHg during MA). Respiratory dead space induced a significant decrease in pH (7 25 ± 0.03, $P < 0.02$) and an increase in $PaCO_2$ values (61 2 ± 6.8 mmHg; $P < 0$ 02). Acidosis increased the fundic tone as reflected by a decrease in barostat volumes from 275 ± 83 to 194 ± 88 ml for MA and from 278 ± 93 to 236 ± 106 ml for RA ($P < 0.05$). Pyloric and duodenal basal tones were not affected by both acidosis. A decrease in pyloric contraction amplitude from 95 ± 24 to 62 ± 26 mmHg during MA and from 94 ± 26 to 64 ± 20 mmHg during RA was observed ($P < 0.05$). Decreased arterial pH nearly abolished phase III of the migrating motor complex (MMC) and altered antral control activity that became dysrhythmic

Conclusions: Acidosis mainly affects antral rhythm and has a major effect on fundic tone and MMC. Acidosis may by this way impair gastric emptying and increase intragastric pressure. These data suggest that acidosis may be implicated in perioperative complications such as gastroparesis, emesis and regurgitations of gastric content.

A.312 Insulin concentrations in samples from stored glucose-insulin-potassium bags

G.R McAnulty, H.J. Robertshaw, G M. Hall *St George's Hospital Medical School, London, UK*

Background and Goal: Intravenous infusion of soluble insulin added to bags of 10% dextrose containing KCl has been advocated as an effective means of obtaining glycaemic control perioperatively in diabetic patients [1] Although there is little evidence that it achieves better metabolic control [2] it does have the advantage of inherent safety. One major drawback is the need to change the insulin content of the bag if good control of blood glucose is not achieved with the initial infusion, which may lead to delay and inaccuracies in altering infusions One way of avoiding this is to have a number of pre-prepared solutions containing varying amounts of insulin There is evidence that insulin is adsorbed onto PVC [3] Availability of insulin and sterility of these solutions after storage has not been determined

Materials and Methods: 5, 10 or 15 units of soluble human insulin (Eli Lilly) and 10 mmol KCl were added 500 ml bags of 10% glucose (Baxter) in a laminar flow room. 5 bags from each insulin group (n = 15) were stored for 7 days, 5 for 3 days and 5 for 24 hours at 4°C

A 312· Table

	1 Day	5 37 (2 14)*	17 91 (7 14)*	6 38 (2 68)*	21 26 (8 95)*	9 90 (4 44)	33 01 (14 79)

(Student's t test (paired variables, two tailed) demonstrated significant differences ($p < 0$ 05) between 1 and 5 hour samples in all groups and adjacent samples except *).

Samples were taken for immunoenzymetric insulin assay (Medgenix-ins-easia, Biosource Europe) of all bags from the distal end of a PVC giving set attached after removal from storage after 1, 3 and 5 hours in a room at 24°C. Samples at five hours were examined microbiologically.

Results and Discussion: Storage time had little effect on the concentration of insulin found. The amount of insulin in samples increased with time out of cold storage and flow through the giving sets Measured insulin values were between 8 and 18% of the expected concentrations in all bags and 22 and 34% after five hours. There was no bacterial contamination

Conclusion: The insulin content of samples taken from pre-prepared 'glucose-insulin-potassium' bags is not affected by storage time at 4°C. However, availability of insulin from 'GIK' bags is low and varies with time out of cold storage.

A.313 Parenteral nutrition supplemented with glutamine improves splanchnic blood flow in an endotoxin rat model

E. Pscheidl, M. Schywalsky. *Klinik für Anästhesiologie, Universitat Erlangen-Nürnberg, Germany*

Background and Goal of Study: Recent evidence indicates that enteral and parenteral formulas supplemented with glutamine are beneficial in states with a decreased barrier function of the gut. This barrier function is partial dependent on a sufficient gastrointestinal blood supply. The aim of the study was to determine the effects of parenteral glutamine application on splanchnic blood flow.

Materials and Methods: After placement of a catheter in the jugular vein 32 Sprague Dawley rats received a continuous parenteral nutrition (1054 kJ/kgBw day) for 96 hours. The caloric ratio of carbohydrates.fat:aminoacids was 38:43:19 The animals of group 1 and 2 received a standard aminoacid solution (Aminofusin®) whereas in group 3 and 4 a glutamine supplemented solution (Glamin®) was used Additionally group 2 and 4 received a continuous infusion of endotoxin (E. coli; 1 mg/kgBW day) in the last 24 hours of the experiment. Blood flow to splanchnic organs was measured using radioactive labelled microspheres. Statistics were performed with the Kruskal-Wallis and Whitney-U-test

Results and Discussion: The results (ml/min g) in the table are shown as mean ± SE.

	1 Standard	2 Standard +E	3 glutamine	4 glutamine +E
Small intestine	1.9 + 0.2	1.4 + 0.2*	2.2 + 0.3	1.8 + 0.2+
Large intestine	0.9 + 0.1	0.6 + 0.1*	1.0 + 0.2	0.9 + 0.1+
Liver arterial	0.3 + 0.1	0.4 + 0.1	0.4 + 0.1	0.4 + 0.1
Liver portal	1.6 + 0.2	1.2 + 0.2*	2.0 + 0.3	1.6 + 0.1§,+

*: $p \leq 0.05$ 1 vs 2, §. $p \leq 0.05$ 3 vs. 4; + $p \leq 0.05$ 2 vs 4,

The glutamine enriched parenteral diet improved the splanchnic blood flow compared to a parenteral nutrition with a standard aminoacid solution This effect attenuated the endotoxin induced decrease of blood flow to the intestine.

Conclusion: These data suggest that a glutamine enriched diet may be beneficial in states where the splanchnic microcirculation is diminished and therefore translocation of gut bacteria occurs.

A.314 Preoperative nutritional assessment using the mini-nutritional assessment: a study on 419 elderly surgical patients

R. Cohendy, F Arnaud-Battandier[2], G. Tran, T. Gros[1], J.-M. Plaze[2], J.-J. Eledjam. *Département d'Anesthésie-Réanimation, CHU de Nîmes, F30029 Nîmes; [1] Clinique Beau Soleil, 119 Av. de Lodève F34000 Montpellier; [2] Nestlé Clinical Nutrition F92316 Sèvres, France*

Background and Goal: The MNA has been specifically designed for assessing nutritional status of elderly patients[1]. Awarding to the obtained score, the MNA stratifies patients in: well nourished (24 ≤ MNA < 30) at risk of malnutrition (17 ≤ MNA < 23.5) undernutrition (MNA < 17) It could be useful because malnutrition is a well-known risk factor. Therefore it was prospectively included in the routine preoperative anaesthesiologic evaluation of surgical patients over 60 to describe the nutritional status of this population.

Methods: Every patient over 60 scheduled for elective surgery was submitted to the MNA. It is a clinical score made of 4 additive items· 'anthropometric assessment' based on Body Mass Index (BMI), mid arm and calf circumferences, weight loss, 'global evaluation', 'dietetic assessment', 'subjective assessment', these last 3 items beeing obtained through a specific questionnaire It requires no biological marker.

The MNA forms were filled on site by the anaesthesiologist seeing the patient. Were also recorded. age gender, ASA class, type of operation Results are given as median [extremes].

Results, Discussion: a *Studied patients.* 419 patients (women: 50.4%) were seen between january and october '96. Age. 72 [60–98] yrs, height: 165 [134–186] cm, weight· 68 5 [34–114] kg, BMI· 25 2 [12 8–40.4] kg m^{-2}. Operations were. digestive surg. 62 8%, orthopaedic surg 22.7%, digestive endosc 6.7%, misc 7.9%. score ASA (see table)·

ASA	1	2	3	4	5
n = 419	82	212	115	10	0
%	19 8	50 6	27.4	2 4	0

b. Nutritional assessment (n = 408):

- Median MNA score = 26 [1.5–30]
- Stratification according to MNA score (see table):

MNA score	<17	17–23 5	≥24
n = 408	28	104	276
%	6 9	25 5	67 6

c. Relation MNA/ASA (see table)

	MNA ≥ 24	MNA < 23	
ASA 1–2	218 (75.2%)	72 (24 8%)	n = 290 (100%)
ASA 3–4	60 (50 %)	58 (49 2%)	n = 118 (100%)

$P = 10^{-4} (X^2)$

Conclusion: Tha MNA is well-suited for critical use because it requires no biological marker. Its use showed that about 1/3 of all the examined patients and half of the ASA 3–4 patients were at least at-risk of malnutrition The ASA score alone could not predict poor nutritional status, but its significant relation to the MNA suggests nutritional assessment should be routinely performed in ASA 3–4 patients over 60.

A.315 Is the helium laparoscopy the best approach for pheochromocytoma surgery?

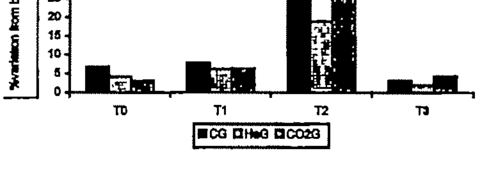
P. Santos, P. Taurà, A. Saenz, I Ornaque, J Fontanals, C Gomar. *Department of Anaesthesiology. Hospital Clinic, University of Barcelona, Barcelona, Spain*

Background: Several studies beings have shown that hipercapnia induced for CO_2-penumoperitoneum produces haemodynamic inestability These physiologic changes could potentially have deleterious effects in patients with pheochromocytoma (FEO).

Aim: This study compares the haemodynamics and plasma catecolamines levels changes (Epinefrine and Norepinefrine) during FEO laparoscopic removal, with helium *versus* CO_2 insufflation for pneumoperitoneum.

Patients and Methods: Twenty patients underwent adrenalectomy were divided in 3 groups according to approach used. He-laparoscopy (HeG, n = 7), CO_2-laparoscopy (CO_2G, n = 7), and open-surgery (CG, n = 6). Variables analyzed were· heart rate (HR), mean arterial pressure (MAP), mean pulmonary arterial pressure (MPAP), cardiac index (CI), systemic vascular resistance index (SVRI), and pulmonary vascular resistance index (PVRI), increase (% from baseline value) of E and NE plasma levels, arterial blood gases and requirements of vasoactive drugs These measurements were recorded at: T0) baseline, T1) after insufflation or during laparotomy (for CG), T2) during tumor manipulation, T3) after adrenal veins were clamped All data are presented as mean ± SEM. Statistical analysis was performed using analysis of variance (ANOVA) and Bonferroni correction test and χ^2 test.

Epinefrine Changes:



Results: Only at T2, CG showed higher MAP and HR than remain ones ($p < 0.05$) At T2 and T3 CO_2G showed higher MPAP and PVRI E and NE plasma levels are shown in figure. Arterial pH and $PaCO_2$ progressively increased in CO_2G HeG had significant lower requirements of vasoactive drugs at all procedure.

Epinefrine changes are shown in the figure

Conclusions: These results suggest that surgical resection of pheochromocytoma can be safely performed by He-laparoscopic approach.

A.316 Early diagnosis of postoperative complications after major oncological surgery. Interest of procalcitonin

D Mokart[1], J.M. Forel[1], M. Merlin[3], M Bonnet[1], J R Delpero[2], G Houvenaeghel[2], G Perrin[1], P Guerre-Berthelot[1], J.L. Blache[1]
[1]*Department of Anesthesia,* [2]*Surgery;* [3]*Biochemistry, Institut Paoli-Calmettes 232 Bd Ste Marguerite, 13273 Marseille cedex 9, France*

Introduction: Post operative complications cause significant morbidity and mortality Successful treatment of these complications needs early diagnosis and appropriate treatment to prevent organ failure. Procalcitonine (PCT) is elevated in patients with sepsis The origin of PCT during systemic inflammation has not been clarified. The aim of this open prospective study was to evaluate PCT and C reactive protein (CRP) as early markers of postoperative complications

Methods: Blood samples were taken perioperatively at D0 (just before surgery) and D1, D2, D3 and D5 (postoperatively) in 15 patients scheduled for major oncologic surgery A standardized anesthesia protocol and prophylactic antibiotic regimen were used for all patients CRP was mesured by nephelemetric technicals (Beckman) and PCT by immunoluminometric technicals (Behring) The patients'postoperative course was classified as complication (infections, septic shock, SIRS, surgical complications) and no complication. Differences between the 2 groups were compared using anova and Student unpaired test

Results: Six patients experienced significant postoperative complications. Comparison between complication group and no complication group showed a statisticaly significant difference at D1 for PCT and at D5 for CRP

	Complication (n = 6)		No complication (n = 9)	
	PCT	CRP	PCT	CRP
D0	0.32	49.2	0.28	38.3
D1	3.80*	114.8	0.89*	93.2
D2	3.23	186	1.72	164.7
D3	3.48	238	1.27	151
D5	1.15	158*	0.67	72*

* $p \leq 0.01$ complication group versus no complication group

Conclusion: These results suggest that PCT in contrast to CRP may be an early marker of postoperative complications in major oncologic surgery patients This preliminary study must be confirmed by subsequent datas.

A.317 Effects of halothane on hormonal secretion of GH3 and AtT-20 clonal cell lines

C. Edwards, A E. Bryant, F Lyons, W. Ali, G.M. Hall *Dept. of Anaesthesia, St George's Hospital Medical School, London, SW17 ORE, UK*

Background and Goal of Study: The precise sites and mechanism of action of volatile anaesthetics remain largely unknown Previous work indicated that the volatile anaesthetic, halothane, can alter various stages in the secretion coupling mechanism of cells (1), but the action of clinically relevant concentrations remains obscure. Therefore we have investigated the effects of halothane (1–4%) on two clonal cell lines with well established secretory mechanisms; GH3 rat pituitary cells and AtT-20 mouse tumour cells.

Materials and Methods: Cells at a concentration of 1×10^{-6} in medium (Hams F10 + 10% horse serum + 5% foetal serum) containing known concentrations of agonists were exposed to varying concentrations of halothane in humidified 95% O_2 + 5% CO_2 for two hours. Control samples were exposed to the humidified carrier gas only Supernatant and intracellular samples were assayed for hormonal concentration (RIA and ELISA) and intracellular protein concentration

Results and Discussion: There was no inhibition of prolactin secretion from stimulated GH3 cells when exposed to halothane for two hours. In contrast, ACTH secretion from stimulated AtT-20 cells was significantly inhibited by 4% halothane·

Halothane	ACTH ng/ml		
	0%	4%	
CRF 10^{-8} M	4.4 ± 1.8	2.9 ± 1.3	p < 0.025
Forskolin 0.1 μM	4.7 ± 1.5	3.7 ± 0.3	p < 0.05

Conclusions: Halothane inhibits pituitary hormone secretion dependent on activation of adenyl cyclase/cyclic acid AMP but has no effects on secretion mediated via protein kinase C However both clonal cell lines showed some cell death at 4% halothane.

A.318 Does isoflurane or nitrous oxide induce micronuclei in human lymphocytes *in vitro*?

G Wiesner, K H Hoerauf[1], K Schroegendorfer[1], M Weindlmayr-Goettel[1], H.W. Rudiger[2], K Taeger *Dept of Anaesthesiology, University of Regensburg, Germany,* [1]*Dept of Anaesthesiology B;* [2]*Dept. of Occupational Medicine, University of Vienna, Austria*

Introduction: Micronuclei (MN) are whole chromosomes or chromosome fragments that are lost during mitosis The induction of MN is a sensitive method for assessing chromosome damage. Since there is an ongoing discussion about the genotoxicity of inhaled anaesthetics, the aim of this study was to assess the potential of Isoflurane or N_2O to induce MN in human lymphocytes in vitro

Methods: With informed consent and approval by the ethics committee, University of Regensburg, lymphocytes were isolated from whole blood of 8 healthy male volunteers and cultured at 37°C for 72 h After 44 h of incubation, cytochalasin B was added to produce binucleated cells (BNC) At the same time exposure to isoflurane or N_2O started Isoflurane concentrations were confirmed by head-space gas-chromatography, concentrations of N_2O by infrared spectroscopy 2000 BNC per sample were scored for the number of MN by immunofluorescent microscopy The mitotic index (BNC/100 Cells) was calculated for evaluating cell proliferation Data were checked for normal distribution and analyzed by ANOVA and paired-sample t-tests

Results:

	MN/500 BNC	Mitotic index
Control	5.0 ± 2.0	20.8 ± 7.8
Isoflurane 0.3 mM	5.0 ± 2.2	18.5 ± 5.8
0.6 mM	5.2 ± 2.8	14.8 ± 6.8*
1.2 mM	5.1 ± 3.1	8.8 ± 2.3*
2.4 mM	na	0.7 ± 0.6*
N_2O/O_2 50%	8.5 ± 1.4*	15.1 ± 6.0*

mean ± SD, * $p < 0.05$ vs Control

Discussion: In vitro isoflurane did not induce MN in concentrations up to 1.2 mM The highest concentration (2.4 mM) could not be evaluated because cell proliferation decreased in a dose-related manner and stopped at 2.4 mM. Cell proliferation is inhibited by volatile anaesthetics (1) The in vitro induction of MN by 50% N_2O/O_2 is in accordance with an increased MN formation in nurses with occupational exposure to N_2O (2). Therefore N_2O is of major concern, when the genotoxicity of a mixed exposure to various inhaled anaesthetics is evaluated

A.319 Role of dimethyl sulphoxide and methylprednisolone in the prevention of halothane hepatotoxicity

B Karamanlioğlu, A. Turan, G Huseyin, O Sengonül, Z Pamukçu ,

In this experimental study, we aimed to investigate the effect of dimethyl sulfoxide (DMSO) and methylprednisolone (MP) on the prevention of halothane related hepatotoxicity

The study was performed on thirty male Wistar-albino rats equally divided into 3 groups Enzyme induction was performed by administration of phenobarbital (1 mg/ml) in the drinking water of the rats for 7 days The rats were anaesthetized by 15%02 + 85%N2O + 0.7% halothane (71/min) for 2.5 hours The control group (n = 10) was given only halothane. The DMSO group (n = 10) was given 20% DMSO (4 g/kg) subcutaneously 2.5 hours before anaesthesia. The anaesthesia. The MP group (n = 10) was given MP (30 mg/kg) iintravenously intravenously 2.5 hours before the anaesthesia Thirty minutes after the anaesthesia, rats were sacrificed and liver samples were taken for free radicals and ultrastructural changes. A significant reduction in the value of malondialdehide which was used for determination of free radicals was observed in DMSO (22495.2 ± 3.76 nmol/g) and MP (24475 ± 3.15 nmol/g) groups in comparison to the control group (29952 ± 4.38 nmol/g) ($p < 0.0015$, $p < 0.0032$). Electron microscopic investigation of the control group revealed marked reversible and irreversible changes in the hepatocyte organelles. In DMSO group the hepatocyte organelles showed marked proliferation and in some of these organelles reversible damage was observed. In MP group marked reversible damage was observed in addition to proliferation of the hepatocyte organelles. In experimental studies free radicals were decreased by DMSO catching hidroxyl radicals and MP lipid peroxidation. (1, 2) We found that DMSO and MP decreased liver injury associated with halothane. As the result, in the DMSO and MP groups significant reduction of the free radicals, and observation of less hepatocytic damage in electron microscopy were determined compared to the control group. We regard to these results, we concluded that DMSO and MP are useful chemical substances which can reduce the hepatotoxic effects of halothane.

Relationship between the ICG elimination rate (CBIig) and the Child-Pugh score in patients undergoing orthotopic liver transplantation

S Acimovic, J. Stark, R. Exner, C.G. Krenn, H Pokorny[1], H Steltzer, M Zimpfer. *Dept. of Anaesthesia and General Intensive Care, [1]Dept of Transplant Surgery, University of Vienna, Austria*

Introduction: Indocyanine green clearance (ICG_{CL}) is a global measure of liver function and is widely used as a prognostic parameter of liver disease since it is sensitive to changes in hepatic blood flow and liver cell function (1). However, ICG is not able to distinguish between hepatic arterial and portal venous blood flow and hepatocyte function. But as a dynamic liver function test it may reflect graft function and may be used to predict graft survival and final outcome (2, 3). In addition, the Child-Pugh-Score is widely used classifying liver dysfunction and failure. This classification includes the development of ascites, encephalopathy, decreasing serum albumin and increasing bilirubin levels, as well as a prolonged prothrombin time. According to the deterioration of liver function each variable is given a value between 1 to 3 points. Therefore the aim of this study was to correlate the CBIig as a simple measure of liver function in patients undergoing OLT with the Child-Pugh grade.

Methods: During a 4 months period 23 consecutive patients (7 F, 16 M) undergoing OLT without venovenous bypass in our center were studied. The patients were classified according to the Child-Pugh Score preoperatively. ICG_{CL} was obtained with a double-indicator dilution technique (the COLD™ system, Pulsion, Munich). The indocyanine green decline in blood was detected by a thermistor-tipped fiberoptic catheter in the descending aorta and ICG elimination rate (CBIig) was calculated. For statistical analysis the unpaired T-Test was used.

Results: Among our patients, 6 have been staged as "A" (solely primary hepatoma), 8 as "B" and 9 as "C" (end stage liver cirrhosis due to viral infection and alcoholic genesis). By looking at the relationship between CBIig and the Child-Pugh-Score we found a significant correlation in patients scored Child A ($p < 0.05$). Whereas patients classified Child B and C showed no significant correlation between the CBIig and the Score ($p = 0.4485$).

Conclusion: Although CBIig and Child-Pugh-Score were correlating in Child A classified patients, this correlation was lost in patients with more severe liver dysfunction. Our findings showed that CBIig can not replace the Child-Pugh-Score when liver function is worsening (Child B and C) but both methods are complementary useful.

Nitric oxide blood concentrations and haemodynamic changes during liver transplantation

E. Cerutti, S. Battista, R. Romagnoli, G. Mengozzi, F. Bar, F. Zamboni, P. Andruetto, M. Salizzoni. *Liver Transplant Center, San Giovanni Battista Hospital-Turin, Italy*

Background & Goal of Study: Nitric oxide (NO) has been implicated in the hyperdynamic circulation of cirrhotic patients. Following graft reperfusion during liver transplantation (LT) such haemodynamic pattern is even more marked. The study aimed at evaluating if changes in NO blood levels take place during the different phases of LT and if they correlate with the haemodynamic profile.

Material & Methods: The study included seven consecutive LT recipients (6 males, 1 female; mean age 44 years, range 28–54). Jugular blood samples were collected at the following times: (A) before skin incision, (B) at the beginning of the anhepatic phase, (C) 5 min before graft reperfusion and (D) 5 min, (E) 15 min, (F) 60 min, (G) 120 min after reperfusion. NO blood levels were assessed by electron paramagnetic resonance spectroscopy. At the same times, cardiac index (CI) was determined by the thermodilution technique with a Swan-Ganz catheter. Data were analyzed with the ANOVA and the Student-Newman-Keuls tests and correlated with the Pearson test, they are expressed as mean ± SEM.

Results: The profiles of NO levels and CI showed significant differences among times ($p < 0.001$). NO levels at time D (8.1 ± 1.5 arbitrary units) were significantly increased in comparison with levels at times A (5.6 ± 1), B (5.3 ± 1) and C (6.5 ± 1.3) ($p < 0.05$). A further peak in NO levels was found at time F (always occurring after arterial unclamping) (9.6 ± 2) ($p < 0.05$ vs all other times except time D). At time G, NO levels (7.9 ± 1.3) remained significantly higher than times A and B ($p < 0.05$). Regarding CI, it was significantly higher at times D, E, F, G (7.2 ± 0.7, 6.4 ± 0.2, 6.5 ± 0.5, 6.3 ± 0.3 $l/min/m^2$, respectively) in comparison with times A, B, C (4.1 ± 0.3, 3.1 ± 0.4, 3.6 ± 0.2, respectively) ($p < 0.05$). Interestingly, a significant negative correlation was found between NO levels and CI at time D ($p < 0.05$, $r = -0.82$), while a positive correlation was observed at time F ($p = 0.02$, $r = 0.83$).

Conclusions: NO levels increase after graft reperfusion during LT, with two successive peaks occurring after portal and arterial unclamping respectively. The negative correlation existing between NO levels and CI just after graft reperfusion suggests that also other mechanisms are involved in the post-reperfusion syndrome, while NO may be responsible for the success ve persistence of a highly hyperdynamic state.

A.322

Soluble heat shock protein (hsp 60) in plasma of liver transplant recipients. A clinical study

C G. Krenn, E. Wildling, G Schett[1], S. Winkler[2], H Pokorny[3], H Steltzer
Dept of Anaesthesia and Intensive Care; [2]Dept of Internal Med I; [1]Dept of Internal Med III; [3]Dept. of Transplant Surgery, Univ of Vienna, Waehringer G 18-20, A-1090 Vienna, Austria

Background: Heat-shock proteins (hsp) are a family of gene products expressed in response to stress and tissue injury and are known to enhance tissue resistance to ischemia. Their expression has been observed during conditions of diminished oxygen delivery i.e. ischemia and reperfusion in organ transplantation and their role in the immune response of graft rejection is gaining increasing interest. Elevated tissue levels were found in acute rejection after experimental heart transplantation and in kidney biopsies from individuals undergoing episodes of acute and chronic rejection [1, 2] Hence, it was the aim of this study to evaluate the release of hsp 60 into plasma of human orthotopic liver transplant (OLT) recipients in the perioperative period.

Material and Methods: After approval by the IRB we investigated 22 consecutive patients undergoing OLT without veno-venous bypass. Measurements were obtained at baseline (tp 0) immediately after induction of anaesthesia, 5 min. (tp 1), 30 min. (tp 2), 4 and 24 hours (tp 3 and 4) after reperfusion of the graft. Hsp 60 release was assessed by a sandwich Elisa using two monoclonal antibodies specific for human hsp 60. Quantification of released protein was assessed by blotting versus a standard extinction curve of serially diluted recombinant human hsp 60.

Results: Up to 340 ng/ml released hsp 60 were detected in central venous blood of transplant recipients, with most of the subjects showing a maximal release after 5 to 30 minutes of initiation of reperfusion. We found baseline levels of more than 150 ng/ml in two subjects. In all patients who underwent uncomplicated OLT, hsp 60 levels returned to or below baseline levels 24 hours after reperfusion. In a patient with prolonged ICU-stay a remaining high level after 24 hours was detected.

Conclusion: Our study demonstrates the release of hsp 60 into plasma of liver transplant recipients in the perioperative period of OLT. We found a time course of hsp 60 within 24 hours after reperfusion in uncomplicated OLT. An early increase in hsp 60 plasma levels might indicate the influence of organ preservation on cellular response, while the role of this molecule as a predictive value for graft rejection after OLT remains to be determined. Additional work is needed to elucidate the possible protective role of hsp 60 during hypoxia/reperfusion injury in OLT and its role in the immune response.

A.323 Blood salvage with "cell-saver" *vs* 100 000 dalton filtration

Juan Catalá[1], José De Andrés[1], Francisco Grau[1], Anders Bengtsson[2], Jan P Bengtson[2] [1]*Department of Anaesthesia, General University Hospital, Valencia, Spain*, [2]*Department of Anaesthesia, Sahlgrenska University Hospital, Gothenburg, Sweden*

Background and Goal of Study: During blood salvage, the recovery of blood components is uncomplete as a fraction is lost in the salvage device We hypothesized that a plasmapheresis filter would traumatise the salvaged blood to a smaller extent compared with centrifugation techniques, thereby permitting that a larger fraction of the red cells should be reinfusable

Materials and Methods: In a randomised laboratory investigation two methods of salvage using some degree of saline wash were studied, a conventional "cell-saver" (Group CS) and salvage by filtration using recirculation through a 100. 000 dalton filter (Group F) The content of the original blood to be processed was known as donor whole blood was used, n = 8 in each group. Median values and ranges are given.

Results and Discussion: Red cell recovery was 82 (73–87)% and 81 (74–94)% in Group CS and Group F, respectively The concentration of free haemoglobin in processed blood was 108 (17–160) and 38 (20–64) mg/L in Group CS and Group F, respectively More free plasma haemoglobin was eliminated to the waste bag with the filtration technique, but the haemolysis in processed blood was low, <0 1%, in both groups The recovery of platelets differed significantly between the groups, 10 (5–23) vs 51 (31–63)% during salvage with conventional red cell centrifugation and filtration, respectively. The median recovery of leukocytes was similar, 48 and 60% in Group CS and Group F, respectively About 20% of albumin, total protein and extracellular potassium was recovered when using filtration, whereas the recovery was minimal, <7%, with the cell-saver

Conclusion: Both methods of autotransfusion caused moderate spillage of red blood cells and the levels of free haemoglobin were low in processed blood Filtration gave a larger recovery of platelets, albumin, total protein and potassium as compared with the cell-saver

A.324 Blood saving in dorsal spondylodesis

D R. Jonker[1], R M Castelein[2] [1]*Department of anesthesiology*, [2]*department of orthopedic surgery, General Hospital de Weezenlanden, Zwolle, the Netherlands*

Background and Goal of the Study: In a retrospective analysis of 44 patients, operated on dorsal spondylodesis, it proved that they had received a number of mean 3.7 ± SD 2.3 packed cells in the perioperative period In the pilot-study presented here, 36 patients, operated on dorsal spondylodesis, were treated in a protocol with four transfusion-reducing techniques The aim of the study was·

1 Reducing blood loss perioperative 2 Preventing or reducing homologous blood transfusions perioperative.

Materials and Methods: Four transfusion-reducing techniques were combined. I. Preoperative autologous blood donation. Every patient donated 3 × 500 ml blood. 4, 3 and 2 weeks before the operation Iron supplement started 5 weeks before the operation II Preoperative autotransfusion with a cell-saver (Haemonetics Cellsaver V). III Hypervolemic hemodilution After induction of anesthesia, 2 × 500 ml of eloHAES 6% (Fresenius) and 500 ml dextrose-saline was infused IV. Controlled hypotension with isoflurane (Abbott) Only normotensive patients were included in the study

Combining profound hemodilution and controlled hypotension can form a risk for the patient. Oxygen delivery can diminish so that a metabolic acidosis develops Moreover reanimation is difficult with the patient in the fixed knee-elbow posture. Therefore the following safety-measures were taken 1. Only ASA I and ASA II patients were included 2. Controlled hypotension only in normotensive patients and not lower than a M.A.P. of 70 mm Hg 3 Maintaining hypervolemia, aiming at a CVP of 10 mm Hg and a diastolic pulmonary pressure of 15 mm Hg. 4. Ht not below 18% and Hb not below 3 5 mmol/ltr. 5 Continuous measurement of the mixed venous oxygen saturation (SvO2) with a thermodilution fiberoptic pulmonary artery catheter (Opticath, Abbott) The SvO2 reflects the amount of oxygen extracted from hemoglobin. In this way oxygen delivery was monitored

Results: During operation all 36 patients received their 3 units of autologous packed cells and 3 units of fresh frozen plasma. No homologous packed cells, plasma or platelets were given during the operation After the operation 8 patients needed homologous transfusions. a total of 16 units of packed cells and 7 units of fresh frozen plasma 28 patients (= 78%) were operated on without any homologous blood transfusion. During operation the lowest values (mean ± S D) of Hb, Ht and SvO2 were Hb 4 3 ± 0.7 mmol/ltr, Ht 22 ± 3%, SvO2 68 ± 6%

Conclusions: 1 Combined use of four transfusion-reducing techniques resulted in a firm decrease of homologous blood transfusions compared with a retrospective analysis

2 Continuous SvO2 measurement seems a reliable monitor to guarantee sufficient oxygen delivery under the circumstances of controlled hypotension in combination with a low hematocrit

NEUROSCIENCES

A.325 Comparison of spontaneous frontal electromyography, EEG power spectrum and bispectral index for predicting emergence after propofol sedation

M Struys, L Versichelen, E Mortier, D Ryckaert, G Rolly *Dep of Anaesthesia, University Hospital, Gent, Belgium*

Background: Many electrophysiologic measures have been developed to monitor depth of anaesthesia and to predict emergence (1) The aim of this study was to investigate the accuracy of frontal spontaneous EMG (SEMG), EEG spectral edge 95% (SEF95), EEG median frequency (MF), EEG relative delta power (RDELTA) and Bispectral Index (BIS) to predict emergence after propofol sedation

Methods and Material: After Ethics' Committee approval, 10 informed patients, receiving spinal anaesthesia for lower limb surgery, received a target-controlled infusion of propofol at 4 4 μg/ml for sedation (2) No other drugs were used and patient were aimed at breathing spontaneously via an oxygen face mask. After 36 min the propofol infusion was stopped The different variables were recorded every min before return of consciousness (ROC) and compared with stable baseline values just before stopping the infusion A reliable measure would show a statistically significant change at least 1 min before reaching ROC A decibel transformation with individualized baselines was used to compare variables with different indices on a common scale (3) Statistical analysis was done with ANOVA and if significant two-tailed t-test for paired data was performed.

Results and Discussion: (mean ± SD) Anthropometric data of the patients (2 male, 8 female) were weight 61 ± 9 8 kg, age 40 ± 9 6 years Accuracy of the different measures to predict ROC are plotted in fig 1 As shown, a trend to decrease in RDELTA was found without statistical significance due to large individual variability Relative decrease in slow-wave activity was reflected in increase of MF and SEF95 For MF, clinical interpretation is difficult due to large interpatient variability A monotonic increasing trend during emergence was found in SEF95 and BIS. SEMG increased only statistically at ROC without predictability

Conclusions: After propofol sedation, the BIS and SEF95 are useful to monitor and predict emergence

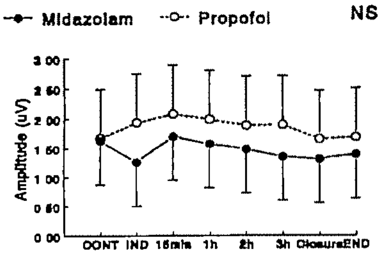
A.326 Effects of propofol-sufentanil *vs* midazolam-sufentanil on cortical somatosensory evoked potentials during major spine surgery

X. Paqueron, B Vivien, F Lille, D Heitz, O Langeron, B Riou, P Coriat *Department of Anaesthesiology, University Hospital of Pitié-Salpêtrière, Paris, France*

Background and Goal of Study: CSEPs enable neurologic monitoring during spine surgery, but they are depressed by most anaesthetic agents. Nevertheless, the combination of opioids and midazolam is recommended because of moderate effects on CSEPs. Thus, we undertook a prospective study to compare the effects of propofol with those of midazolam during major spine surgery

Patients and Methods: 20 patients were randomly allocated to a propofol (P) or midazolam (M) group. Anaesthesia was induced with either P (3 mg.kg^{-1}) or M (0.3 mg.kg^{-1}), associated with sufentanil (S) (1 μg.kg^{-1}) and vecuronium (0.1 mg kg^{-1}) in both groups; then anaesthesia was maintained with a continuous infusion of either P (10 mg.kg^{-1}h^{-1} for 1 h then 6 mg.kg^{-1}h^{-1}) or M (0.15 mg.kg^{-1}h^{-1}) with in both groups S (0.5 μg kg^{-1}h^{-1}) and oxygen in air (F_iO_2: 60%) We recorded the latencies (P40 and N50) and the amplitude of CSEPs in the awake state (control), and during surgery (induction, 15 min, 1 h, 2 h, 3 h and at the end of the procedure). Statistical analysis was performed by repeated-measure analysis of variance and Newman-Keul's test. Data are mean ± SEM

Results and Discussion: There were no significant differences between groups for age, sexe, duration of surgery and sufentanil doses. We did not observe any significant difference between groups concerning CSEPs latencies (P40, N50) and amplitude (figure). Nevertheless, a significant greater delay of the first voluntary postoperative motor response was observed in the M group as compared to the P group (112 ± 19 vs 44 ± 8 min, $P < 0.05$)



Conclusion: In our study, both anaesthesia regimens allowed a reliable CSEPs monitoring, but M significantly increased the delay of first voluntary postoperative motor response.

A.327 Effects of calculated plasma sufentanil concentration on the haemodynamic and the bispectral index responses to mayfield head holder application

P. Hans, B. Hubert, J.F Brichant, P.Y. Dewandre, G. Byttebier, E. Coussaert, F. Cantraine, M Lamy. *University Dpt of anesthesia and Intensive Care Medicine, CHR Citadelle, CHU Liège; Biometrics Unit, Zeneca N.V., Dept of Computer Science, Free University of Brussels, Belgium*

Introduction: The placement of cranial pins is an acute nociceptive stimulation during intracranial surgery The present study was designed to evaluate the effects of two calculated plasma sufentanil concentrations on the hemodynamic and the Bispectral index (BIS) changes induced by Mayfield head holder (MH) application in neurosurgical patients.

Methods: After Ethics committee approval and informed consent were obtained, 20 ASA I or II patients scheduled for intracranial surgery were studied. Premedication consisted of hydroxyzine, alprazolam and atropine given orally 1 h before surgery. Anesthesia was provided with propofol (PPF) and sufentanil (SUF) using a target-controlled infusion device Patients were randomly assigned to one of two groups according to calculated plasma concentrations: 3 μg ml^{-1} PPF and 0.5 ng ml^{-1} SUF in group I, 3 μg ml^{-1} PPF and 1 ng ml^{-1} SUF in group II. The MH was fixed 33 ± 6.6 min (mean + SD) after induction. Systolic (SAP), diastolic (DAP), mean arterial pressure (MAP), heart rate (HR) and BIS were recorded 1 min before pinning (baseline), 1 min (P1), 2 min (P2) and 3 min (P3) after pinning. Multivariate repeated-measured analyses of variance were applied to the baseline-subtracted measurements of hemodynamic and BIS values. The data were also compared between groups at the different times, using the Student's *t* test $P < 0.05$ was considered statistically significant.

Results: Patients characteristics as well as baseline hemodynamic and Bis values were similar in both groups. Significant overall time effect was observed for all variables but no significant overall SUF effect was detected Increases in SAP, MAP, DAP and HR did not differ significantly between groups. However at P1, the increase in BIS over baseline value was significantly higher in group I (15.0 ± 7.9) than in group II (6.7 ± 6.5).

Mean hemodynamic (mmHg, beats/min) and BIS values at the different times in both groups

Variable	P1		P2		P3		*P* value				
	G1	G2	G1	G2	G1	G2	G1	G2	Time	Drug	Interac
SAP	99.5	104.7	114.8	116.3	111.7	114.0	107.3	108.6	0.002	0.64	0.74
MAP	75.3	75.9	88.9	86.5	83.7	83.1	83.1	80.5	0.008	0.77	0.70
DAP	65.5	63.0	77.4	72.5	71.5	69.6	72.7	68.7	0.016	0.45	0.49
HR	64.9	57.2	71.4	62.7	69.3	61.1	67.0	59.9	0.008	0.17	0.80
BIS	41.4	45.8	56.4	52.1	46.5	46.1	41.6	45.2	0.0001	0.79	0.06

Discussion: Application of the Mayfield head holder was associated with a significant increase in hemodynamic variables whatever the calculated plasma SUF concentration (0.5 or 1 ng ml^{-1}). However, that increase did not exceed 20% of baseline value in both groups In contrast, the increase in BIS observed at pinning was significantly higher in patients with the lowest calculated plasma SUF concentration, suggesting a possible effect of the analgesic level on BIS during nociceptive stimulations.

A.328 The differences in somatosensory evoked potentials changes and neurological deficit according to the location of temporary clips of cerebral arteries

Jong-Hoon Kim, Yong-Taek Nam. *Department of Anesthesiology, Yonsei University, College of Medicine,*

Background and Goal of Study: Somatosensory Evoked Potentials (SSEP) have been frequently used to monitor cerebral ischemia during cerebral aneurysm surgery. SSEP changes and their relation to postoperative neurologic deficit have been studied many times[1, 2] but the differences according to the location of temporary clips have not yet been evaluated The aim of this study was to evaluate if there are any differences in SSEP changes and neurologic deficit according to the location of temporary clips (middle cerebral artery [MCA], internal carotid artery [ICA] and both anterior cerebral arteries [ACA]) and types of SSEP (median nerve SSEP [M-SSEP] and posterior tibial nerve SSEP [P-SSEP]).

Materials and Methods: We studied 80 patients undergoing anesthesia and cerebral aneurysm surgery. M-SSEP was monitored for MCA and ICA temporary clipping, and P-SSEP for both ACA temporary clipping. SSEP were recorded after induction of anesthesia and dural opening (control value), during temporary clipping, and after relieving temporary clips. A change in cortical amplitude of more than 50%, as compared with control was considered 'significant'. The records were graded as follows: Type I, no change; Type II, insignificant change; Type III, significant change with a complete return to baseline; Type IV, significant change with an incomplete return to baseline. The differences in temporary clip time according to the location of temporary clips, and presence of significant SSEP changes and neurologic deficit were analyzed using one-way ANOVA and unpaired Student's *t*-test

Results and Discussion: Some SSEP changes of MCA clipping reflected neurologic deficit but SSEP changes of ICA or both ACA clipping hardly reflected it.

Type of SSEP	Postoperative Neurologic Examination					
	Normal/Unchanged			Increased Deficit		
	MCA	ICA	ACA	MCA	ICA	ACA
I	18	12	12	1	0	0
II	5	7	7	0	0	1
III	5	7	4	1	0	0
IV	0	0	0	1	0	0

There was no difference in temporary clip time according to the location of temporary clips But temporary clip time was significantly prolonged if there were significant SSEP changes or neurologic deficit.

Conclusion: SSEP can be used to detect significant cerebral ischemia due to MCA clipping. But SSEP monitoring for ICA or both ACA clipping is not so useful in detecting ischemia.

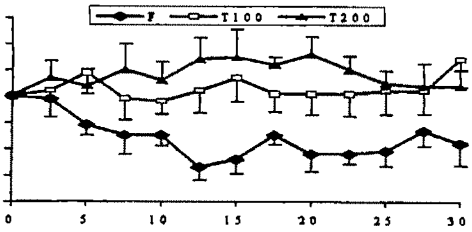
A.329 Effect of tramadol and fentanyl on somatosensory evoked potentials in sedated volunteers

S Hussain, G J. Hobbs, B.R. Baxendale. *University Department of Anaesthesia, Queen's Medical Centre, Nottingham, NG7 2UH, UK*

Background and Goal of Study: Tramadol, a centrally acting analgesic, inhibits noradrenaline and serotonin (5-HT) re-uptake, stimulates 5-HT release and has weak opioid μ-receptor activity [1]. Previous data demonstrated that tramadol can cause EEG activation during anaesthesia [2]. Its effect on spinal cord monitoring is unknown. Fentanyl (75 mcg.kg^{-1}), a pure opioid agonist, does not affect somatosensory evoked potentials (SSEP's) [3]. We compared the effect of tramadol and fentanyl on SSEP's during propofol sedation.

Materials and Methods: We studied 8 healthy volunteers aged 20–35 yr. During 3 sessions, each 2 weeks apart, volunteers were sedated with iv propofol to a target plasma concentration using a 'Diprifusor' for a 60 min period. Cortical SSEP's (tibial nerve stimulation) were recorded at 2.5 min intervals throughout each session using C_z-F_z scalp electrodes, and amplitudes A_1 (P1-N1) and A_2 (N1-P2) were measured. At 30 min the study drug [either iv fentanyl 100 mcg (F), tramadol 100 mg (T100) or tramadol 200 mg (T200)] was given over 3 min Venous blood for measurement of plasma propofol concentration was sampled at 30 and 60 min. ANOVA with repeated measures and the paired t-test were used to analyse data.

Results and Discussion: Baseline measurements at steady state sedation for each volunteer were recorded. A_1 decreased significantly after F compared with T100 ($P = 0.029$) and T200 ($P = 0.003$). A_2 showed a similar trend but this was not statistically significant. Plasma propofol concentrations were comparable. The graph shows the percentage change of A_1 from baseline against time (min) following administration of the study drugs



Conclusion: Fentanyl produced a significant decrease in P1-N1 amplitude during sedation with propofol when compared with either dose of tramadol.

A.330 Effects of propofol infusion on central conduction time during carotid endarterectomy

A Yoshino, S. Nagashima, K. Kataoka, M Uchiyama. *Department of Anaesthesiology, Nihon University School of Medicine, Japan*

Introduction: Cortical somatosensory evoked potentials (CSEP) allow monitoring of cerebral functions and central conduction time (CCT) It is especially used to detect ischemia during neurosurgical procedures. CCT, however, is affected by volatile anesthetics depending upon the concentration used[1]. The effects of propofol on CCT, however, has yet to be studied. We, therefore, recorded CSEP and measured CCT during CEA under TIVA using propofol to determine if there are any changes in CCT corresponding to the doses of propofol used

Methods: Nineteen adult patients aged 67.5 ± 8.4 scheduled to undergo CEA for carotid stenosis participated No premedication was used Anaesthesia was induced with 2 micro gram/kg fentanyl and 1–2 mg/kg propofol after which trachea was intubated following 0.1 mg/kg vecuronium. Anaesthesia was maintained with continuous infusion of propofol, intermittent fentanyl, and oxygen enriched air Mechanical ventilation was kept at ETCO2 at 35–40 mmHg. Blood pressure was maintained at 140–150 mmHg and the body temperature at 34°C or over. CSEP were recorded with transcutaneous electrodes located in the C7-Fz and C'3 (C'4)-Fz elicited by alternate median nerve stimulation. The time between N13 and N20 was regarded as CCT. CCTs were measured before induction, after induction but before the temporary clamping of carotid artery, and during the clamping. During the CCT measurements the rate of propofol was gradually increased from 2 to 10 mg/kg/h then reduced again to 2 mg/kg/h and measurements were made at every 2 mg/kg/h to observe if the changes in CCT depended upon the rate of propofol used. Comparisons were made among the concentrations and with the value of control.

Results and Discussion:

	2	4	6	8	10
Before clamping	6.75	6.78	6.80	6.82	6.86
After induction	6.71	6.79	6.76	6.80	6.83
During clamping	6.81	6.83	6.83	6.83	6.90

That there was no significant differences in CCT between each rates of infusion of propofol in different occasions suggests propofol does not affect CCT in any doses used, or at least not below 10 mg/kg/h. This means propofol allows us to obtain reliable CCT during CSEP monitoring for CEA.

Conclusion: Propofol is useful for CSEP monitoring during CEA as this drug enables us to adjust the rate of infusion as required to get adequate depth of anaesthesia regardless of the CCT measurements for detecting the cerebral ischemia during the surgical procedure

A.331 Dose-dependent suppression of motor evoked potentials by propofol

C. Thees, K.M. Scheufler[1], J Zentner, D Gordes, U Pechstein[1],
J. Nadstawek. *Departments of Anaesthesiology and Neurosurgery[1], Rheinische Friedrich-Wilhelms-Universität Bonn D-53105 Bonn, Germany*

Aim of the Study: Exact knowledge of the influences of anaesthesia on motor evoked potentials (MEP) is required for interpretation of MEP findings during intraoperative monitoring Since it is frequently used for total intravenous anaesthesia (TIVA) in neuroanaesthesia, propofol is of particular interest Therefore, we designed this study to investigate the effect of increasing doses of propofol on MEP.

Methods: Following local ethics committee approval and informed consent ten neurosurgical patients were included in the study. Transcranial magnetic stimulation of the motor cortex was performed with different numbers of pulses (single, double and quadruple) and interstimulus intervals (2, 5 and 10 ms), as well as increasing stimulus intensities (0.6 to 2 tesla). MEP were recorded from three muscle groups of the upper limb Using a target controlled infusion (TCI) pump, propofol infusion was gradually increased up to a target plasma concentration of 6 μg/ml in 1 μg/ml steps MEP were recorded on each target plasma level. Ventilation was assisted by mask as appropriate.

Results: Under stable and reproduceable conditions threshold intensities (single pulse) were established Increasing doses of propofol led to a dose-dependent suppression of MEP amplitudes The amplitudes of the evoked muscle responses were related to stimulus intensity, number of pulses and ISI. Even with supramaximal stimulus intensity (single pulse, threshold + 30%), muscle responses were abolished in 7 of 10 patients at target plasma levels of 2 μg/ml. However, with quadruple pulse stimulation and an ISI of 2 ms, MEP could be recorded in 5 of 10 patients at target plasma concentrations of 3 μg/ml, whereas MEP at the same stimulus intensity were lost with increasing ISI (10 ms).

Discussion: Our investigation shows a dose-dependent suppression of magnetic MEP by propofol. With propofol plasma concentrations of 3 μg/ml required for maintenance of a surgical anaesthetic level[1], reliable intraoperative monitoring of myogenic MEP seems not to be feasible. Even magnetic quadruple pulse stimulation with an ISI of 2 ms, which achieved best results during propofol anaesthesia, did not ensure reliable intraoperative recording of myogenic potentials.

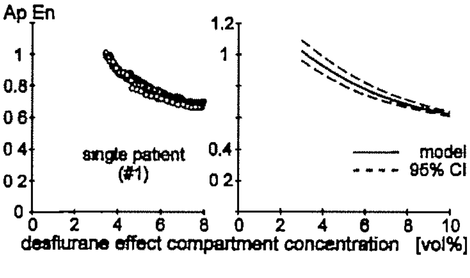
A.332 The "approximate entropy" as an EEG parameter of anaesthetic depth?

J. Bruhn, H. Ropcke, A. Hoeft. *Department of Anaesthesiology, University of Bonn, Germany*

Background and Goal of Study: We hypothesized that the EEG during deep anaesthesia will show more "order" and less "random" than at lower levels of anaesthesia. To quantify regularity we examined the concentration dependence of the approximate entropy[1] (ApEn) in a desflurane mono-anaesthesia during surgery.

Material and Methods: After having obtained institutional approval and informed consent, 12 female patients, age 33–65 yr, who underwent abdominal surgery, were included in the study. After induction of anaesthesia with propofol they received desflurane as the sole anaesthetic agent for maintenance. Between opening and closure of the peritoneum desflurane vapor settings were randomly varied between 0.5 and 1.6 MAC, as long as a clinically adequate depth of anaesthesia was maintained The endtidal concentrations (Capnomac™, Datex) of desflurane were measured. A 3-lead EEG was stored with 125 Hz, the ApEn was computed from 2^{10} data points (= 8.192 s) Median EEG frequency (median) and SEF 95 were calculated, additionally we determined the bispectral index (BIS) (Aspect A-1000). A sigmoid inhibitory E_{max} model was fitted to the concentration-EEG data.

Results and Discussion: The ApEn decreased continuously over the observed concentration range of desflurane (Fig) The Performance of ApEn as an indicator for desflurane concentrations is similar to median, SEF 95 and BIS: We calculated a prediction probability Pk of 0.86 ± 0.06



for ApEn, 0.78 ± 0.06 for median, 0.86 ± 0.06 for SEF 95 and 0.82 ± 0.06 for BIS (mean ± SD), (a value of 1 means indicator predicts anaesthetic concentration perfectly, a value of 0.5 means indicator predicts no better than a 50·50 chance) [2] The low computation time for ApEn allows an on-line analysis.

Conclusions: We believe, that the "approximate entropy" could be an alternative EEG parameter for the on-line analysis of anaesthetic depth.

A.333 Burst suppression or silent EEG for maximal cerebral metabolic suppression: evidence from flow-metabolism studies

P.W Doyle, A K Gupta, B M Matta. *Department of Anaesthesia, Addenbrooke's Hospital, Cambridge, UK*

Background and Goal: Reducing cerebral metabolism may increase the margin of safety in those patients with neurologic injury. This study was designed to investigate whether maximal level of EEG suppression was superior to burst suppression.

Materials and Methods: After obtaining local ethics committee approval and written informed consent, 7 patients (5 F, 2 M, Age 52 5 ± 14 5) undergoing general anaesthesia for resection of acoustic neuromas were recruited. Patients received a standard anaesthetic with routine monitoring (ECG, invasive arterial blood pressure, CVP, pulse oximetry, end-tidal capnography and jugular venous bulb catheter for jugular oximetry – SjO2) At the end of the operation, anaesthesia was maintained with propofol and remifentanil, and the lungs were ventilated in 50% oxygen and air to normocapnia (PaCO2 4 81 ± 0 3 Kpa). Blood pressure was maintained within 15% of baseline with phenylephrine infusions when necessary. EEG activity and burst suppression ratio (BSR) were measured using a bifronto-parietal montage (Aspect A-100, Natick, USA). The middle cerebral artery blood velocity (Vmca) was measured throughout the study with a 2 MHz transcranial Doppler probe (DWL, Sipplingen, Germany) During a period of stable haemodynamics, the EEG activity was varied by adjusting the depth of anaesthesia Vmca and SjO2 were measured at 0%, 50% and 100% BSR and the arterio-venous O2 difference (A-V DO2) was calculated The cerebral metabolic equivalent (CME) was calculated by multiplying the Vmca by the A-V DO2. The results were compared using ANOVA, with a p-value < 0 05 considered significant

Results: The main results are shown in table 1. There were no statistically significant differences in MAP, HR, or PaCO2 at the 3 levels of BSR.

BSR vs CME and % reduction in CME

BSR	0%	50%	100%
CME	254 ± 27	208 ± 20*	160 ± 15*
% reduction CME	0%	17% ± 4**	40% ± 2**

Values are mean ± SE, * p < 0 05, ** p < 0 01

Conclusions: EEG silence is associated with a lower CME than 50% BSR. This may increase the margin of safety in the neurologically injured The effect this has on outcome requires further evaluation

A.334 A study of adenosine treatment in experimental acute spinal cord injury: effect on arachidonic acid metabolites

E.A. Akpek, E Bulutçu, A Alanay, P. Korkusuz, Ü. Ors, E. Acaroğlu. *Başkent and Hacettepe University Medical School, Ankara, Turkey*

Background and Goal: Vascular mechanisms, production of eicosanoids, free radicals and lipid peroxidation are possible mechanisms of secondary injury after acute spinal cord trauma[1, 2]. In this study the effect of adenosine on arachidonic acid metabolites and lipid peroxidation was investigated in a prospective, randomized, blinded experimental design.

Methods: 37 adult, Wistar-Albino rats were laminectomized and studied in four groups. Group 1 underwent a sham operation. Group 2 received 100 μcg/kg/min IV infusion of adenosine. In group 3 spinal cord trauma was established with the "weight-drop" technique and group 4 received adenosine infusion following trauma. Spinal cord specimens for biochemical and histopathological examination were collected at 30 minutes in all groups. Data were analyzed with Kruskal-Wallis and Mann Whitney U tests.

Results and Discussion: Adenosine infusion after trauma limited the increases in lipid peroxidation but the difference was significant at p = 0.06. The structure of myelin was well preserved in adenosine treated trauma group. However the changes were irreversible in severely damaged areas.

	Group 1	Group 2	Group 3	Group 4
LTC_4 (ng/g)	0 89 ± 0 07	0 46 ± 0 10	1 58 ± 0 09*	1 00 ± 0 10
PGE_2 (ng/g)	2 37 ± 0 30	1 70 ± 0 20	2 30 ± 0 30	4 38 ± 0 40#
MDA (nmol/g)	65 0 ± 7 3	64 4 ± 6 1	78 3 ± 7 8	72 7 ± 7 3

*p < 0.01 compared to group 1, #p < 0 001 compared to other groups

Increased LTC_4 levels increased after trauma indicates the shift of cerebrovasculature response to the vasoconstrictor side. Adenosine infusion following trauma however, Increased PGE_2 levels suggesting that this shift in the balance to the vasodilation side could have beneficial effects on blood flow thus resulting in a possible protective effect in overall.

Conclusion: Following acute spinal cord trauma IV adenosine infusion of 100 μcg/kg/min could attenuate the progression leading to secondary injury but this effect was not effective alone yet.

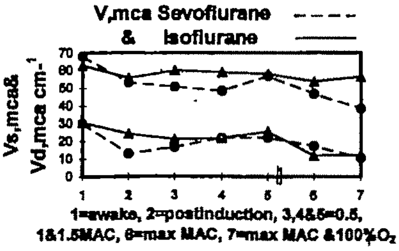
A.335 Comparison of sevoflurane and isoflurane on middle cerebral artery blood flow velocity

A C Quinn, J.M. Freeman, G. Parkin, E. Moss. *Academic Unit of Anaesthesia, Leeds General Infirmary, S1L 3EX, UK*

Background and Goal of Study: This study compared the effect of isoflurane and sevoflurane with 70% N_2O in O_2, or 100% O_2, on middle cerebral artery blood flow velocity (V, mca) using the transcranial doppler method. Volatile anaesthetic agents affect cerebral autoregulation. Cho et al[1] demonstrated a decrease in mean V, mca with 1 2 MAC sevoflurane in 100% O_2 which was reversed when N_2O was added.

Materials and Methods: After ethics committee approval, we prospectively randomised 20 ASA grade 1 or 2 patients aged 18–70 yrs to receive either agent. Baseline systolic and diastolic V, mca (Vs, mca, Vd, mca), pulsatility index (PI) and mean arterial pressure (MAP) and heart rate (HR) were measured. After a 20 mg temazepam premed, pre-O_2, and a 1L 0.9% NaCl, thiopentone 4 mg/kg, fentanyl 2 mcg/kg, dropendol 15 mcg/kg and vecuronium 0.1 mg/kg were used to facilitate induction and ventilation via a laryngeal mask airway. Maintenance was with 70% N_2O in O_2 at normocapnia. The volatile was commenced at 0.5 end-tidal MAC and increased by 0 5 MAC increments until MAP fell by 50%. A final measurement was taken at maximum MAC with 100% O_2. Differences between the groups at this endpoint were calculated using the t-test, with significance at p < 0.05.

Results and Discussion: 11 patients received isoflurane and 9 sevoflurane (1 exclusion as a poor doppler trace). Demographic details were comparable and mean trace quality, depth of insonation, HR, MAP and max MAC did not differ between the groups. There was little difference between mean (SD) Vs, mca at maxMAC, but a difference when N_2O was removed and 100% O_2 administered: 38 7 (13.2) v 58 6 (16) cms^{-1} p = 0 032, for sevoflurane and isoflurane respectively.



Conclusion: Our results indicate a similarity in the effects of isoflurane and sevoflurane with N_2O on V, mca The difference at maxMAC in 100% O_2 appears to be a paradoxical effect of sevoflurane on cerebral blood flow resistance in that vasodilatation is occurring under vasoconstricting influences

A.336 Dynamic cerebral autoregulation during sevoflurane anaesthesia. A comparison with isoflurane

A. Summors, B Matta, A Gupta. *Department of Anaesthesia, Addenbrooke's Hospital, Cambridge, CB2 2QQ, UK*

Background: Inhaled anaesthetics impair the ability to, and the rate of autoregulation in a dose dependant manner. This study examined the effect of 1 5 MAC sevoflurane on dynamic autoregulation.

Methods: After obtaining local ethics committee approval and written informed consent, 16 adults (ASA 1–2, age 54 ± 10 yr, weight 81 ± 11 kg) undergoing non-intracranial neurosurgical procedures were recruited. Patients were allocated to have dynamic cerebral autoregulation (dROR) tested during either sevoflurane or isoflurane anaesthesia With routine monitors in place (ECG, pulse oximetry, end tidal CO_2 and noninvasive blood pressure (Finapress, Ohmeda, U S A), patients received a standardised anaesthetic consisting of propofol 2 5 mg/kg, fentanyl 1 5 μg/kg, and vecuronium 0 1 mg/kg. The lungs were ventilated with 1 5 MAC volatile agent in 100% oxygen to normocapnoea (end tidal CO_2 5 2 ± 0 2 kPa) When necessary, blood pressure was maintained within 20% of baseline levels with an infusion of phenylephrine

Autoregulation Testing: Middle cerebral artery blood velocity (Vmca) was measured using a 2 Mhz transcranial Doppler probe (DWL, Sipplingen, Germany) The probe was fixed in position throughout the study period Vmca and mean arterial blood pressure (MABP) were displayed continuously. Large thigh cuffs were used to evoke a drop in blood pressure Cuffs were inflated to 100 mmHg above systolic pressure for 3 minutes Rapid deflation resulted in approximately 20 mmHg drop in MABP Using an algorithm previously validated, the Vmca response to the drop in MABP was fitted to a series of curves which were used to determine the rate of dROR dROR values were compared using ANOVA P value < 0.05 was considered significant

Results: The main findings of this study are shown In Table 1. There was no significant difference between the two groups in heart rate, MABP, drop in blood pressure, end tidal CO_2 or Vmca The rate of autoregulation awake was within normal limits

Dynamic Rates of Autoregulation

dROR (%/sec)	Sevoflurane	Isoflurane
Awake	29 ± 2	32 ± 2
1 5 MAC	24 ± 2*	4 6 ± 1**

Values are mean ± SE *significantly different from baseline, p < 0 01 **significantly different from baseline and sevoflurane, p < 0 01.

Conclusion: Dynamic autoregulation is better preserved during sevoflurane anaesthesia.

A.337 Blood flow velocity of middle cerebral artery during mask induction of anaesthesia with high concentrations of sevoflurane in adult patients

J L Hanouz[1], C Daubin[1], L Auvray-Lefrancois[1], P. Cabal[2], J M Derlon[2], J.P Houtteville[2], J L Gérard[1], H Bricard[1]. [1]*Dept of Anesthesiology, CHU Côte de nacre, Caen;* [2]*Dept of neurosurgery, CHU Côte de nacre, Caen, France*

Background & Goal of the Study: It has been shown that high concentration of sevoflurane may be used for induction of anesthesia in adults [1] However, effects of high concentration of sevoflurane on mean blood flow velocity of middle cerebral artery (Vmca) during mask induction of anesthesia remains unknown in adults

Materials & Methods: After approval of the local medical ethics committee and informed consent, 6 ASA 1 adult patients, without cerebral disorder, were included in this study Patients were breathing room air before induction of anesthesia and baseline value of Vmca was then measured using a transtemporal approach (DWL Multidop, Germany) The transcranial doppler probe was maintained at constant position by use of a suitable holder attached to the patient's head. Then, patients were allowed to breath spontaneously high concentration (8 vol%) of sevoflurane in oxygen Heart rate (HR), non invasive mean arterial blood pressure (MAP), inspired and end tidal concentrations of gases were continuously monitored Vmca was then measured continuously during 30 minutes Data are mean ± standard deviation

Results: After introduction of sevoflurane (8 vol%) Vmca rapidly increased reaching a peak value (161 ± 19% of baseline value) at 10 ± 3 minutes During this time, heart rate, mean arterial blood pressure, and end tidal CO_2 ($EtCO_2$) were not significantly modified

Parameters measured at baseline value and ten minutes after 8 vol% of sevoflurane

	Vmca (cm/sec)	$EtCO_2$ (mmHg)	HR (bpm)	MAP (mmHg)
Baseline	41 ± 5	36 ± 4	81 ± 11	103 ± 5
10 min	65 ± 2*	33 ± 7	82 ± 14	102 ± 7

* P < 0 05 vs baseline value

Conclusion: Mask induction of anesthesia using high concentrations of sevoflurane with the spontaneous ventilation technique induced a significant increase of Vmca suggesting a cerebrovascular dilation

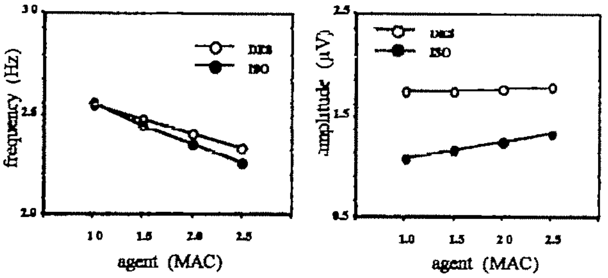
A.338 Effect of desflurane vs isoflurane on intraoperative EEG in elderly patients

M. Solca, M. Averu, E. Dellino, G Veschi, R Russo *Istituto di Anestesia e Rianimazione, Università degli Studi, Ospedale Maggiore, Milano, Italy*

Background: Halogenated inhalation anaesthetics reportedly effect reduction in frequency and increase in amplitude of cortical EEG We wish to present our initial experience on a small number of elderly patients anaesthetised with desflurane, a new potent halogenated agent, in whom intraoperative electrical cortical activity was monitored, as compared to similar patients receiving isoflurane

Methods: During a previously reported Investigation (1) on ASA II and III elderly patients (≥65 years of age), 18 patients (11 receiving desflurane/N_2O and 7 isoflurane/N_2O anaesthesia) were monitored, as a specific operating room clinical practice, with a Datex Cerebral Function Monitor (CFM), in addition to routine monitoring After standard premedication and induction, inspired anaesthetic was titrated to maintaining systemic blood pressure and heart rate within 20% of baseline value End-tidal agent concentration was continuously measured and recorded every 15 min Throughout the procedure (open urological surgery) the CFM measured and plotted every 3 min the average zero-crossing frequency and mean amplitude of cortical EEG. For each patient the CFM tracing, from induction to anaesthesia discontinuation, was divided in 6 equal epochs. The first one was discarded, as expression of initial anaesthetic equilibration, for each subsequent period, the modal EEG frequency and amplitude were taken as representative, and correlated with the correspondent anaesthetic end-tidal concentration (expressed as MAC) Slope and Intercept of 18 individual regressions were averaged, Student's t test was applied to compare regression parameters between the two agents

Results: The two patient groups were comparable in term of demographics, surgical duration and anaesthetic exposure (average MAC) Desflurane induced a MAC proportional decrease of frequency (Hz = 2.699 – 0 149 MAC) and increase of amplitude (μV = 1 691 + 0 038 MAC) on EEG, very similar (figure below) to modifications induced by isoflurane (Hz = 2 716 – 0.183 MAC and μV = 0 911 + 0 165 MAC, respectively) Slope and intercepts for both frequency and amplitude were not statistically different between anaesthetics.



Conclusion: In elderly patients desflurane appears to effect cortical EEG changes (frequency reduction and amplitude increase) very similar to Isoflurane

A.339 Fast-track supratentorial craniotomies. Experience of 100 patients

N. Sáiz-Sapena[1], V Vanaclocha[2], A. Sáez-Fernández[1], J M Sánchez[1], I Olavide[1], R Maña[1] *Departments of* [1]*Anaesthesiology and* [2]*Neurosurgery, University Clinic, School of Medicine, University of Navarra, Spain*

Background & Goal of Study: Prompt recovery is one of the standards of anaesthesia for brain tumours excision It is not that easy for the patient who has received large doses of opioids, Inhalational agents or others At this respect, short-acting both opioids and inhalational agents are very helpful, but still the patients show some residual effects that can interfere with neurological examination

Based on our experience on awake craniotomies (1), we started a program on minimal anaesthesia for the removal of supratentorial brain tumours with the aim of getting some fast-track brain surgery This program included head nerves block, minimal doses of opioids, under-MAC inhalational agents and immediate awakening after surgery

Patients & Methods: In the past two years we have performed a series of 100 fast-track craniotomies for resection of supratentorial gliomas, meningiomas or metastasis Patients were classified as ASA I–II, and aged 18–73 yrs Tumours affecting the cranial base were excluded

Induction of anaesthesia was obtained with propofol 2 mg/kg, fentanyl 1 μg/kg and atracurium 5 mg/kg Afterwards nitrous oxide 50–60% plus isoflurane 0 6% were used. A bolus of propofol 0 04 mg/kg was administered just before head nerves block, and if needed during surgery. To reduce the analgesic requirements, anaesthetic block was performed on those nerves which innervate the scalp and muscular area to be manipulated during surgery, selected among these: frontal (internal + external), zygomaticus-temporalis, temporo-mandibularis, superior auricularis, lower occipital and greater occipital. Each point was anesthetized with only 1–2 cc bupivacaine 0.5% with epinephrine 1:200.000. The incision line was also infiltrated, with a mixture of 10 cc bupivacaine 0.5% with epinephrine 1:200 000 + 10 cc lidocaine 2%. Dura was afterwards anesthetized with cottonoids soaken in lidocaine 2%. After closing the dura inhaled agents were discontinued and a propofol perfusion of 5 mg/kg/h started, and spontaneous ventilation allowed The perfusion was stopped 10 minutes before the end of surgery. The patients were extubated immediately after surgery, neurologically assessed, and transferred to the ICU.

This series of patients was compared with a previous one of traditional anesthesia without head nerve block, with greater doses of opioids, muscle relaxants and inhalational agents, and extubation in the ICU.

Results & Discussion: There were no significant differences between groups in background factors and those related to operation, as duration of surgery. Intraoperative hemodynamic stability was much better in the head nerves block group. Neurological assessment could be quickly and accurately performed in the same operating room or immediately on arrival to the ICU in all patients Patients were discharged from the ICU in 12 to 18 h Their analgesic requirements were also lower They received only one dose of metamizol 8-hrly either iv (2 g) or po (575 mg) The patients could be discharged from the hospital on the 3rd–4th postoperative day

Conclusions: Head trunk nerves block is a useful tool in supratentorial craniotomies to perform fast-track neurosurgery

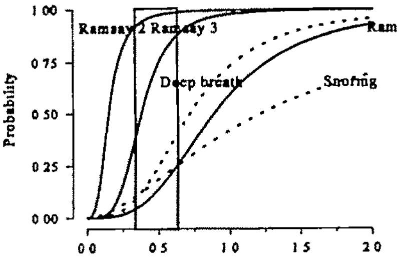
A.340 Propofol sedation using a target controlled infusion system in patients undergoing stereotactic pallidotomy

R Valero, P. Gambús[1], N. Fábregas, I F. Trocóniz[2], E. Carrero, C. Gomar. *Anesthesia Dpt, Hospital Clínic de Barcelona, [1]Anesthesia Dpt., Hospital de Viladecans Barcelona; [2]Pharmacy Dpt Universidad deNavarra, Pamplona, Spain*

Background and Goal of the Study: Stereotactic pallidotomy is a long lasting surgical procedure where the patient must be awaken, during microstimulation periods. Sedation with propofol allows fast recovery in the precise moment when surgeons need it. Our goal was to estimate the propofol predicted concentration (C_{pred}) ranges that permit adequate sedation to this patients, using a TCI system[1].

Materials and Methods: 3 adult consenting patients were enrolled in the study. All were premedicated with benzodiacepines in the ward Before starting surgery, a target C_{pred} was chosen and the pump started infusing. After allowing for equilibrium between plasma and effect site, sedation score (SS) (Ramsay sedation scale) and the degree of respiratory obstruction (RO) (1: no obstruction, 2: deep breath, 3: snoring, 4: severe obstruction), were measured and recorded At any change in the target level, a new measurement of SS and RO was performed. Logistic regression was used to relate the C_{pred} to the probability of being at (or deeper) level of sedation and respiratory obstruction



Results and Discussion: A total of 71 C_{pred}-effect measurements were done The mean duration of propofol infusion was 365 min. C50 were estimated for all SS and RO levels. The relation between C_{pred} and SS 2, 3 and 4 as well as RO scores 2 and 3, are shown in the graph. The rectangle highlights the levels of C_{pred} associated with adequate sedation without relevant respiratory obstruction.

Conclusion: A target C_{pred} of 0 5 mg/L will keep 75% of patients at sedation score 3 and only 14% at level 4. This concentration is associated with a probability of snoring of 0 12 It can be used as a safe starting point for sedation in this subpopulation of patients

A.341 Intraoperative complications during pallidotomy for Parkinson's disease. A review of 30 cases

E Carrero, R. Valero, N Fábregas, J. Rumià[1], F. Valldeonola[2]. *Dpt Anestesiology; [1]Neurosurgery, [2]Neurology, Hospital Clínic de Barcelona, Barcelona University, Spain*

Background & Goal of Study: Stereotactic pallidotomy is being used as a treatment for medically refractory Parkinson's disease. This neurosurgical intervention is not free of intraoperative complications Although, references on this subject are scarce in the literature.

Our aim has been to point out the frequency and importance of these complications, in order to prevent and treat them promptly.

Material & Method: 30 consecutive patients with Parkinson's disease, who underwent a stereotactic pallidotomy (23 cases) or implantation of a thalamic electrode (7 cases), were studied After the CT scan to localize the target, patients were transported to the operating room and monitored (ECG. pulsioximeter, continuous arterial pressure, $ETCO_2$, urine output) and sedated with propofol (discontinued perfusion) depending on the surgical step. Complications appearing during the procedure were registered. After operation patients overnight in the Postanesthetic recovery room

Results and Discussion: Patients (21 male, 7 female) were sedated with a mean dose of propofol 715 mg (SD.472) during pallidotomy Mean duration time of the procedure was 9.9 hours (SD: 2.6). Intraoperative complications were Mild arterial hypertension, registered in 15 patients, upper airway obstruction appeared in one patient (no tracheal intubation was needed); symptomatic air embolism without hemodynamic changes were noted in 2 patients; arrhythmia (2), anisocoria (1) and seizures (1) were also registered.

Every incident could be treated successfully and intervention could be finished without major complications.

Conclusions: Deep brain recording-guided pallidotomy can be performed with local anesthesia, but the procedures may take a long time, and, in our institution, we prefer to use "conscious sedation". With propofol "discontinuous" infusion the neural noise levels could be detected without interferences. A high rate of minor and potential major complications appeared in our series. Invasive monitoring and promptly detection and treatment of intraoperative complications is mandatory.

A.342 Brain mapping in assessment of the functional state of the brain

V. Chemiy *I Department of Intensive Care, Medical University, Donetsk, Ukraine*

Background & Goal of Study: Comparison of clinical neurological data to results of the EEG spectral analysis for deriving an integrated exponent of encephalopathy's degree

Materials & Methods: 116 patients with encephalopathies resulting from carbon oxide poisoning (36), postasistolic syndrome (16), brain trauma (30), acute renal failure (7), septic shock (3) and control group (14) were observed. All the patients were admitted in coma (9–21 points according to Glasgow-Pittsburgh Coma Scale).

Electroencephalography (brain mapping) was fulfilled by means of encephalograph "Medicor" in 8 monopolar channels. The estimation of EEG patterns by Zhirmunskaya method [1] was carried out. There were analyzed results of rapid transformation Furie of EEG after rhythmical photostimulation 2, 6, 10, 20 Hz and therapeutical prescriptions. We studied also the figures of absolute and relative power in such diapason: delta (1–4 Hz), theta (5–7 Hz), alpha (8–12 Hz), Beta1 (13–25 Hz), Beta2 (25 Hz and more).

Results: All EEG changes were divided into following types: I-organized (3, 4 groups) (group of control); IV-disorganized with prevalence of alpha-waves (12, 13, 14 groups); V-disorganized with prevalence of delta- and theta activity (16, 17, 18, 19, 20 groups) by Zhirmunskaya classification For quantitative evaluation of EEG-patterns' deterioration we've created coefficient (Delta + Theta + Beta1)/(Alpha + Beta2). Idea of which is based on the fact that Beta2-waves are obligatory component EEG, and Beta1-waves are not typical for the norm [1, 2]. Degree of EEG disorders are presented in table:

Type of EEG	Group of EEG	n	Coefficient	GPS	Degree of EEG disorders
I	3, 4	14	0 96–1.05	35	no disorders
IV	12–15	29	1 6–2 3	29-21	significant
V	17, 18	38	2 5–4.0	18-11	severe
V	19–20	35	4 2–5 5	9-7	extr severe

Is established that coefficient (D + T + B1)/(A + B2) reflects a degree of EEG deterioration, revealed as a result of EEG pattern processing by

Zhirmunskaya method; it was significant degree in 12–15 EEG groups, severe – 17–18, very severe – 19–20. In the EEG groups 3–4 with no EEG disorders coefficient was about 1 (no coma), in patients with extremely severe EEG disorders coefficient varied from 4.1 to 5.5 (coma III).

Conclusion: Coefficient (D + T + B1)/(A + B2) correlates with numerical evaluation of coma depth.

A.343 Activity of AST in the cerbrospinal fluid in patients with severe brain injury

D. Vujadinović, N. Gačić, V. Vujin, O. Potparić, T. Jovanović, M. Stošić
Department of neuroanaesthesia, Emergency Centre, Clinical Centre of Serbia, Belgrade, Yugoslavia

Background & Goal of Study: When the cerebral integrity is affected by cerebral trauma, pathological penetration of enzymes into the CSF takes place. This is correlated with degree of neural tissue damage. The aim of the study is to determine the depth of coma according to the CSF enzyme level in cases of cerebral trauma and to undertake prompt and aggressive treatment of these patients.

Material & Methods: The study included 40 patients at the neurosurgical emergency care of the Emergency Centar, Belgrade. AST levels were measured in comatose patients with CT evidence of contusion. On days 1, 3 and 5 after the injury, blood samples were obtained by venepuncture and CSF by lumbal puncture (L4–L5).

Results: AST enzyme activity in the serum five days after the injury remains within the normal values. AST activity in the CSF is highly correlated with GCS on the fifth day after the injury so that it is possible to precisely predict the outcome of treatment and prepare patients for cadaveric transplantation on time (AST 85 U/l, GCS 6).

Conclusions: In severe brain contusion aspartate aminotransferase (AST) was proved to be both clinically and prognostically significant.

A.344 Thromboelastographic assessment of coagulation during surgery for meningioma

A. Babinet-Berthier[1], B. Mebtouche[1], M.A. Pech-Amsellem[2], J. Philippon[3], J.J. Guillosson[2], M. Samama[1], P. Conat[1] *[1]Dept Anaesthesiology; [3]Neurosurgery; [2]Surgery Laboratory, Pitié Salpétrière Hospital, Paris, France*

Changes in haemostasis are often observed in patients undergoing intracranial surgery for meningioma. A concomitant increase in thromboembolic complications and in local fibrinolytic activity have been reported (1). Several mechanisms have been suggested out of which a tumoral release of factors able to alter the haemostatic balance (2). Thromboelastography (TEG) enables a global and dynamic assessment of haemostatic function in whole blood (3). Some TEG variables are analysed: *r* represents the rate of initial fibrin formation, related to the clotting factors and inhibitors, *k* is the clot formation time, mainly affected by the activity of clotting factors and, as well as *alpha angle* and *MA* maximum amplitude, by fibrinogen and platelets. We have measured the potential variations in TEG parameters and usual coagulation tests during meningioma surgery, with or without preoperative embolisation.

Patients and Methods: 22 patients scheduled for meningioma surgery were included. Blood samples were drawn at T0 (before surgery) and at T1 (during surgery after total tumor resection). Blood samples were tested immediately in a computerized TEG Coagulation Analyzer®. Usual clotting tests (PT, APTT, Thrombin time, platelets count, hematocrit, and fibrinogen) were performed at the same time.

Statistical Analysis: a Wilcoxon rank test was used (m ± SD).

Results and Discussion:

Variables (normal range)	Total n = 22		Embolisation n = 9		Non embol. n = 13	
	T0	T1	T0	T1	T0	T1
r (mm) (19–28)	9.3±2.9	9.8±4.4	9.7±2.6	9.4±3.3	9.1±3.2	10±4
k (mm) (8–13)	3.5±1	4.2±2.1	3.7±0.7	4±1	3.4±1.2	4.3±2.7
MA (mm) (48–60)	62.4±6	56.3±9.4*	59.6±5	57.2±6.2	64.3±7.5	55.7±11*
α (°) (29–43)	66.9±5.3	64.6±9.6	64.4±4.4	65.3±5	68.8±5.2	64.0±11

The preoperative profile (T0) of the 22 patients was hypercoagulable, as compared to normal values provided by the manufacturer. At T1 a trend in r and k lengthening and alpha angle decrease were observed while a significant decrease in MA is noted in the non-embolised group, suggesting an impairment in clot strength. No concomitant change in usual coagulation tests was documented.

Conclusion: TEG points out an hypercoagulable state undetected by usual coagulation tests and responsible for the high risk of thromboembolism related to meningioma. Surgery of non-embolised tumor seems to limit this hypercoagulable profile probably through a release in tumoral factors.

A.346 Effect of hypertonic saline solution on increased intracranial pressure secondary to traumatic brain injury

Ana Domínguez-Berrot, Juan Carlos Ballesteros, Elena Rodríguez, Silvia Gutiérrez, Javier Collado, Daniel Fontaneda. *Unidad de Cuidados Intensivos. Hospital de León. Altos de Nava. León, Spain*

Objective: To evaluate the effect of 7.5% NaCl on systemic and brain hemodynamics in acute traumatic brain injury (1, 2).

Materials and Methods: Eleven patients with traumatic brain injury (GCS less than 9), both with and without associated injuries elsewhere, and showing cardiovascular stability. Neurosurgical treatment was not necessary for any patient at that time. A Swan-Ganz catheter was placed in every patient to monitor systemic hemodynamics. Blood pressure, pulse rate and central temperature were continuously recorded. We also registered the hemoglobin level, as well as systemic ventilation and oxygenation. We monitored intracranial pressure (ICP) (intraparenchimal sensor, Camino V4209 monitor) and 02 saturation in the jugular vein (SjvO2) (Opticath Umbilical 4F Abbott).

Every apyretic patient whose ICP was 20 mm Hg or more after being sedated (midazolam and fentanyle), paralyzed (atracurium), slightly hyperventilated depending on their SjvO2, with no hemodynamic disturbance and no less than 10 gr/100 cc hemoglobin received a 1 ml/kg bolus of 7.5% NaCl. The above mentioned variables were measured before, and 5, 30 and 60 minutes after the administration of the hypertonic saline solution.

Statistical analysis: mean ± SD. $p < 0.05$

Results: ICP decreased significantly and cerebral perfusion pressure (CPP) increased significantly as well. The rest of the variables investigated did not change significantly (table).

	Basal	5 min	30 min	60 min
ICP	30.6 ± 7.44	21.2 ± 6.2*	20.7 ± 7.19*	19.8 ± 7.43*
CPP	66.62 ± 5.62	79.13 ± 0.4*	82.2 ± 1.08*	79.97 ± 0.82*
MAP	97.22 ± 13	100.33 ± 6.3	102.9 ± 8.27	99.77 ± 8.25

*p < 0.001

Conclusions: Hypertonic saline solution was effective in decreasing ICP and improving CPP with no change in any other systemic or cerebral hemodynamic variable.

A.347 Cerebral arteriovenous P_{CO_2} difference as a measure of cerebral ischaemia in severe head injury

E. Zavala, F.X. González, J. Ibañez, N. Fábregas, C. Balague, R. Adàlia, G. Martínez, L.A. Moreno. *Surgical ICU. Hospital Clínic. University of Barcelona, Spain*

Background and Goal of Study: In head trauma patients, oxygen cerebral metabolism and cerebral blood flow are impaired. During this period, ischemia patterns have been described elsewhere. In clinical practice, cerebral arteriojugular difference of oxygen content ($AjDO_2$) monitoring has been used to detect and prevent cerebral oxygenation imbalance (1). In this patients different index have been used to evaluate cerebral ischemia (2). The aim of this prospective study is to compare the arteriovenous PCO_2 difference ($AVDPCO_2$) with the other index of cerebral oxygen metabolism as a index of cerebral ischemia in patients with severe head injury.

Material & Methods: Sixty severe head trauma patients (GCS < 8), underwent multivariate physiologic studies involving cerebral perfusion pressure (CPP), oxygen jugular saturation (SjO_2), $AjDO_2$, arterio-jugular lactate difference (AVDL), and $AVDPCO_2$, by monitoring jugular bulb oxymetry immediately after their admission in our unit. According to the first determination of $AVDO_2$, patients were separated in three different groups Group I: patients with increased AVDO2 > 8 ml/dl hypoperfusion – ischemia, Group II. patients with $AVDO_2$ = 5–8 ml/dl: normal and Group III: patients with decreased $AVDO_2$ <5 ml/dl: hyperemia. These values were compared (ANOVA for repeated measurements) with the other index of cerebral oxygen metabolism

Results and Discussion: Eleven patients presented ischemic profile, twenty one patients had normal $AVDO_2$ and twenty six presented hyperemia after their admission in SICU. $AVDPCO_2$ was 14.6 ± 9 5, 8.7 ± 2 6 and 5 6 ± 4.1 in groups I, II and III respectively, ($p < 0.05$). AVDL was 1 9 ± 2 5 in Group I, 0.9 ± 1 2 in group II and 3.4 ± 5 in the third group (NS). CPP were 75.6 ± 11 3, 74 7 ± 17 1 and 77 ± 14.1 respectively (NS) and finally CEO_2 in the group I was 53.3 ± 4 7%, 37.8 ± 5 3% and 23.9 ± 8.7% in the group II and III respectively ($p < 0.05$) In the group I, all patients had increased CEO_2 and only 3 patients showed a $AVDO_2$ > 8 after 24 hours, with a wide $AVDPCO_2$, and S_jO_2 < 55%, in spite of the therapeutic maneuvers to improve oxygen cerebral supply. Two out of these 3 patients died (GOS = 1) and one was discharged with moderate disability (GOS = 4) In this study, during the early ischemic phase, $AVDPCO_2$ were greater than normal in group I, and could have been due to a reduction in CBF with oxygen supply dependency (ischemia) and anaerobic CO_2 production.

Conclusions: We can conclude that in head trauma patients, the arteriovenous PCO_2 difference can provide a good method, in the clinical practice, to confirm global cerebral ischemia and that increased CEO_2 may suggest relative cerebral hypoperfusion

Correlation of changes in jugular venous oxygen saturation with tissue oxygenation in head-injured patients undergoing hyperventilation therapy

A.K. Gupta[1,2], M. Swart[1], S Gupta[1], P. Al-Rawi[3], P. Hutchinson[3], P Kirkpatrick[3], B Matta[1,2], D K. Menon[1,2] [1]*Departments of Anaesthesia,* [2]*Neuro Critical Care; and* [3]*Neurosurgery, Addenbrooke's Hospital, Cambridge, UK*

Background: Monitoring cerebral oxygenation is of great importance in minimising secondary hypoxic and ischaemic brain injury in severely head injured patients. Jugular venous oximetry is the most established method of measuring global cerebral oxygenation and has been particularly useful in monitoring hyperventilation therapy in head injured patients. However, this method of monitoring is not sensitive to regional changes in oxygenation More recently tissue sensors have been used to continuously measure regional tissue oxygenation ($PTiO_2$)[1]. We have compared the changes in jugular bulb oxygen saturation (S_jO_2) and $PTiO_2$ in areas of focal pathology (eg contusion) and outside areas of focal pathology during hyperventilation therapy.

Method: After Local Ethics Committee approval and informed consent, ten patients presenting with severe head injury were studied. A multiparameter sensor (Paratrend 7, Diametrics Medical High Wycombe, UK) was inserted through a specially designed triple lumen bolt into brain tissue Subsequent CT scans confirmed the position of the sensor. A jugular venous catheter was inserted into the right jugular bulb Invasive haemodynamic pressures and ICP were also monitored. Patients were hyperventilated in a stepwise manner by increasing the minute ventilation to decrease the $PaCO_2$ by 0 5 kPa at each step down to a $PaCO_2$ of 3 0 kPa.

Results: Mean CPP, PaO_2 and temperature did not change significantly. Examination of the CT scans revealed the sensor placed inside an area of focal pathology in 4 patients and outside an area of focal pathology in 6 patients. The *change* in S_jO_2 against the *change* in tissue oxygenation showed a good correlation when the sensor was inserted outside an area of focal pathology ($r^2 = 0.68$, $p < 0\,0001$) but no correlation when the sensor was inserted into an area of focal pathology ($r^2 = 0.07$).

Conclusions: (1) S_jO_2 does not always reflect changes in regional oxygenation

(2) Targeted placement of sensors will enable detection of regional changes in brain tissue biochemistry which will not be reflected by jugular bulb oximetry

(3) Measurement of $PTiO_2$ may be a useful adjunct to S_jO_2 in monitoring global cerebral oxygenation

CSF *vs* jugular lactates to detect ischaemia during sustained hypocapnia in head injuries. Preliminary results

S Manrique[1], A Ausina[1], M A. Poca[2], M de Nadal[1], C. Godet[1], J Sahuquillo[2], A. Garnacho[3] [1]*Departments of Anesthesiology;* [2]*Neurosurgery; and* [3]*Neurotraumatology Intensive Care Unit Vall d'Hebron University Hospitals. Barcelona, Spain*

Background and Goal of Study: Jugular lactates have been found to be less accurate to detect ischemia during a sustained situation of low cerebral blood flow (CBF) than cerebral spinal fluid (CSF) lactates[1]

Our goal in this study was to compare both jugular and CSF lactates during sustained hyperventilation (HV) in head injuries.

Material and Methods: Eight adult patients with head injury and increased intracranial pressure (ICP) were included and prospective studied. CO_2-reactivity was tested according to previously reported methodology[2]. Within 72 hours after accident patients were hyperventilated for a period of 4 hours During this time pCO_2, jugular (S_jO_2) and arterial oxyhaemoglobin saturation (SaO_2) and ICP were recorded at 30 minutes, 1 hour, 2 hours and 4 hours. Arterial, jugular and CSF lactates were also measured before HV and at 30 minutes and 4 hours after induced hypocapnia Arterio-jugular differences of oxygen ($AVDO_2$) and lactates (AVDL) were then calculated. Results are expressed as mean ± SD or median (min/max) as appropriate.

Results: At the times described pCO_2 values were 35.2 ± 1.8; 31.2 ± 4.6; 27.4 ± 3.9; 26.1 ± 2 5 and 28 2 ± 5 1, and ICP values were 25 (8/68), 7 (1/33), 8 (2/27), 15 (10/44) and 20 (7/43) respectively. According to AVDL no patient developed anaerobic metabolism (AVDL > –0 42 μmol/ml), while CSF lactates were higher than normal values (2 mmol/L[1]) in 3 cases at basal point, 5 cases at 30 minutes of HV and in 7 cases at 4 hours of HV.

Conclusion: CSF lactate values were higher than jugular values during HV. Our results suggest that CSF lactates were more reliable than jugular lactates to detect anaerobic metabolism, although more cases are necessary to confirm this data.

Hormonal and haemodynamic consequences of moderate hypothermia in head injured patients

W. Meissner, H Fritz, B Dohm, C Krapp, K. Reinhart. *Clinic of Anesth. and Intensive Care, F.-Schiller-University, 07740 Jena, Germany*

Background: Moderate hypothermia improves neurologic outcome after severe head injury (1). However, mild accidental hypothermia activates parts of the sympathoadrenergical system (2), whereas more pronounced hypothermia depresses it (3). The aim of this randomised controlled investigation was to study the effect of intended moderate hypothermia on the cardiovascular and cortisol response in severe head trauma.

Methods: After IRB approval, 16 patients with severe blunt head injury were either treated with moderate hypothermia (32–33°C, n = 7) or with normothermia (36–37°C, n = 9). Hypothermia was induced within 8 h after trauma and maintained for 48 h Patients were analgosedated at least for three days Heart rate (HR), mean blood pressure (MAP) and plasma cortisol were measured five times during the hypothermia- or corresponding normothermia period and several times after rewarming Norepinephrine (NE) was used to keep cerebral perfusion pressure (CPP) > 65 mm Hg.

Results: Medians of heart rate and mean blood pressure were slightly lower during hypothermia compared to the corresponding normothermia period. Demand of NE for maintaining sufficient CPP was lower in the hypothermia group. Plasma cortisol concentrations did not differ (Tab). During rewarming, heart rate increased to 96 beats/min but blood pressure did not change. Cortisol concentrations increased 4 to 7 days after trauma in most patients of either group. Differences were not statistically significant.

Median HR, MAP, plasma cortisol concentrations and NE infusion in the hypothermia and normothermia group Perc 25%/75% percentile

	32°C	Perc.	37°C	Perc
HR (/min)	67	63/79	96	87/96
MAP (mm Hg)	86	79/90	91	85/91
Corts (nmol/l)	282	256/320	258	178/339
NE (μ/kg/min)	0 16	0 13/0 28	0 31	0 31/0 32

Conclusion: Moderate hypothermia for 48 h after head injury depresses HR and MAP without requiring higher catecholamine dosing. A stress reaction in terms of a cortisol increase was not observed. This findings may indicate that intended moderate hypothermia of 32°C in analgosedated patients neither activates nor depresses the sympathoadrenergic response to the same degree reported during mild or severe hypothermia.

A.351 Evaluation of carbon dioxide-reactivity and autoregulatory mechanisms in patients with severe head injury

M de Nadal[1], A. Ausina[1], F Munar[1], J. Sahuquillo[2], M. Báguena[3], A Garnacho[3], V A. Gancedo[1] *Departments of [1]Anesthesiology; [2]Neurosurgery; [3]Neurotraumathology Intensive Care Unit, Vall d'Hebron University Hospitals, Barcelona, Spain*

Background & goal of the study: The status of autoregulatory mechanisms after severe head injury has been a matter of considerable debate Maintaining CPPs above the threshold of 60–70 mmHg should be the main goal in the management of severe head injury, but in patients with impaired autoregulation this could led to an increase in brain volume and ICP. The purpose of this study was to elucidate the status of autoregulatory mechanisms and cerebrovascular CO2 reactivity in patients with severe head injury.

Material & Methods: A prospective study was carried out in 41 patients with severe head injury (Glasgow ≤ 8). Mean arterial blood pressure (MABP), intracranial pressure (ICP), cerebral perfusion pressure (CPP) and oxyhemoglobin saturation (SjO2) were continuously monitored. Cerebral blood flow (CBF) was estimated from AVDO2 and all values corrected for changes in pCO2. CO2 reactivity (CO2R%) was calculated as the percent increase or decrease of estimated CBF per mmHg change in pCO2 To classify autoregulation, we used Enevoldsen criteria (1) for patients in whom ICP changed ≤2 mmHg after increasing MABP. In those patients in whom ICP changed >2 mmHg we used different criteria previously described (2).

Results: Mean age was 30 4 ± 13 (mean ± STD) and GCS was 5.7 ± 1.6. According to corrected basal AVDO2 values, 28 (73.7%) patients were classified as hyperemic (AVDO2 < 1.74 μmol/ml). Cerebrovascular response to CO2 was preserved in all but 2 cases (CO2R% < 1%) In contrast, autoregulation was preserved in 17 (41.4%) and impaired/abolished in 24 (58.5%) At six months, 8 patients died, 1 was in a persistent vegetative state and 9 were severely disabled. Therefore, bad outcome was the final result in 44% of our series.

Conclusions: Although the majority of patients in our study preserved CO2 reactivity, most of them had an impaired/abolished autoregulation during the first 48 hours after injury.

A.352 Effect of propofol on lipid peroxidation and oedema in experimental brain injury

H. Madenoğlu, A Boyaci, R.K. Koç, I Karakuçük, M Erşepçiler, A Akın. *Department of Anaesthesiology, Neurosurgery and Biochemistry, Erciyes University, Faculty of Medicine, Kayseri, Turkey*

Introduction: Preventing and reducing secondary brain injury have bee the focus of recent researches on CNS trauma. Trauma-induced lipid peroxidation is one of the most important factors producing tissue damage in head injury (1). the purpose of this study was to evaluate the antioxidant neuroprotective effects of propofol on cerebral after moderate head injury in rats.

Material and Methods: After approval by the Corporate Animal Welfare Committee of Erciyes University, 24 adult, male, Swiss Albino rats, weighing 200–250 mg were divided randomly to control and propofol groups. Moderate diffuse head injury in rats was performed as described by Mamarou et al (2). A simple head injury device was designed to induce blunt trauma to the protected skull of the rat. A cylindrical column of brass weighing 450 gm was allowed to fall through a 2-m plexiglas tube onto a small rounded stainless-steel disc fixed to the central portion of the skull vault of the rat. The animals were anesthetized by a mixture of ketamine (60 mg/kg) and diazepam (6 mg/kg) injected i p and placed in the prone position n a foam bed with the disc centered immediately under the lower end of the tube of the trauma device Two belts were fastened around the trunk of the rat to prevent it form falling of the foam bed after trauma induction. The weight was allowed to drop freely from the 1-m height through the tube onto the disc The foam bed together with the rat was moved away from underneath the tube immediately after impact to a single hit. A catheter was placed in the right femoral vein for drug administration The propofol group rats received an I.v infusion of propofol (5 mg/kg) for 2 h. and the control group rats received i.v equal volumes of saline solution. Rats were breathing spontaneously throughout the experiment. After 2 h of the experiment, each rat was killed and the brains were rapidly removed. The left and right hemispheres were separated and weighed Malondialdehyde (MDA) was measured by the thiobarbituric acid test and brain water content was determined as the ratio of wet weight to dry weight

Results: The level of total MDA was lower in propofol group than the control group but there was not statistically significant differences between control and propofol groups (p > 0.05). There was no significant differences in brain water content between control and propofol groups (p > 0 05).

	Control	Propofol	p
LP (nmol MDA/g wet wt)	311 ± 39	277 ± 55	1 5
Water (%)	73 ± 8	70 ± 5	1 1

Conclusion: The results of the present study prove that the beneficial effect of propofol in the treatment of traumatic brain injury could be related to decreasing the peroxide lipid products produced as a result of the initial injury. However, further studies should be done in order to determine how long and which doses can be administered to produce significant beneficial effects

A.353 Oestradiol improves ischaemic neuronal damage in gerbil hippocampus

N. Adachi, J. Chen, K. Liu, K. Dote, T Arai. *Department of Anesthesiology and Resuscitology, Ehime University School of Medicine, Shigenobu, Ehime 791-02, Japan*

Background: The depolarization of the neuronal membrane in cerebral ischemia triggers the release of excitatory neurotransmitters, which is regarded as a crucial factor in the development of neuronal damage Because gonadal hormones influence the metabolism of various neurotransmitters in the mammalian brain, we examined the effects of estradiol and progesterone on the histologic outcome and the anoxic depolarization in ischemia

Methods: Experiment 1 (Histology)· Male Mongolian gerbils weighing 60–80 g were anesthetized with halothane, and the bilateral common carotid arteries were exposed. After the animal was placed in a stereotaxic apparatus in the prone position, estradiol (3, 10, or 30 μg), progesterone (30 μg), or saline (10 μL) was injected intracerebroventricularly. Transient forebrain ischemia was then induced for 3 min by occluding the bilateral common carotid arteries, while the brain and rectal temperatures were maintained at 37.5°C. The histologic outcome was evaluated 7 days after the ischemia by assessing the delayed neuronal death in the hippocampal CA1 pyramidal cells

Experiment 2 (Anoxic depolarization). After the preparation of transient forebrain ischemia, a glass micropipette with a tip diameter of 4 μm was implanted in the right hippocampal CA1 field. The potential shift was monitored between this electrode and the remote electrode. Transient forebrain ischemia was induced and changes in the potential shift were compared among animals pretreated with estradiol (3 μg), progesterone (30 μg), and saline. The data from the two experiments were evaluated by ANOVA with Bonferroni's adjustment.

Results: The number of preserved pyramidal cells was 25 ± 17/mm (mean ± SD, n = 5) in the control group. Estradiol increased the number of preserved neurons, the effect being significant at a dose of 30 μg (171 ± 70/mm, p < 0.01). Progesterone did not affect the histologic outcome. The forebrain ischemia produced a sudden and acute shift in the potential at an onset latency of 54 ± 11 s in the control group with a maximum amplitude of 22 ± 3 mV. Neither estrogen nor progesterone affected the anoxic depolarization.

Conclusion: The pretreatment of estradiol mitigates the ischemic neuronal damage without affecting the anoxic depolarization

A.354 Potassium channel blockers blunt hypoxic cerebral vasodilatation in the awake dog

G. Audibert[1], S. Ricco[2], A. Legris[3], D. Hartemann[2], J Lambert[2], C.S. Saunier[2], M.C Laxenaire[1]. *[1]Dépt. d'anesthésie-réanimation; [3]Service de Chirurgie générale, Hôpital Central; [2]U14 INSERM, Nancy, France*

Background: During hypoxia, the cerebral blood flow (CBF) increase may be mediated by activation of ATP sensitive potassium (K+) channels (1). The present study investigated the effect of glibenclamide and glipizide, on CBF during acute hypoxia in the awake dog

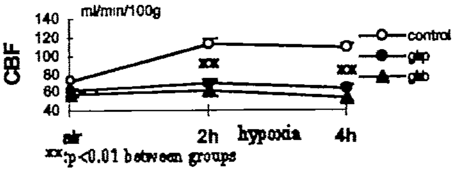
Methods: Sixteen Beagle dogs (mean weight 12 ± 2 kg) were studied. On the study day, the dogs were studied awake during three periods: in normoxia and after 2 and 4 h normocapnic hypoxia in a 45 m3 atmosphere controlled chamber (FIO2 = 10%, FICO2 = 3.5%, FIN2 = 86.5%) During both first stages, the animals were randomly allocated to receive glibenclamide (glib) 10 mg/kg (n = 6), glipizide (glip) 10 mg/kg (n = 6) or placebo Thirty minutes later, after hemodynamic measurements and arterial blood withdrawal for blood gases, glycemia and K+ measurements, radiolabelled microspheres (Ce^{141}, Ru^{103} ou Sc^{46}) were injected into a left atrial catheter for regional CBF measurements The brain was totally dissected in 38 samples.

Results: Mean PaO2 decreased from 84 ± 2 mmHg in air to 44 ± 2 mmHg in hypoxia without differences between groups. Biological results are shown in the table

		Air		Hypoxia	
		baseline	treatment	2 h	4 h
	control	4.4 ± 0.1	4.0 ± 0.1	3.9 ± 0.1	4.3 ± 0.2
K+	glib	4.0 ± 0.1	3.6 ± 0.1*	3.4 ± 0.1**	3.3 ± 0.1**°
	glip	4.1 ± 0.1	3.7 ± 0.1*	3.6 ± 0.1**	3.8 ± 0.1
	control	5.3 ± 0.1	7.6 ± 0.6*	6.9 ± 0.6	5.4 ± 0.1
Gly	glib	5.2 ± 0.2	7.3 ± 0.5**	4.2 ± 0.5	3.4 ± 0.3**°
	glip	5.5 ± 0.1	7.4 ± 0.5**	5.5 ± 0.4	3.8 ± 0.3**

Gly: glycemia (mmol/l) K+ potassium (mmol/l), * $p < 0.05$, ** $p < 0.01$ vs baseline, ° $p < 0.01$ vs control group

In the control group, CBF increased by 53% after 2 h and 46% after 4 h hypoxia This increase was blunted after glib and glip (figure) Regional CBF followed the same patterns in all areas



Conclusion: There were moderate glycemia changes induced by sulfonylureas, but hypoglycemia is known to enhance CBF (2). These results suggest that potassium channel activation plays a key role in cerebral regulation

A.355 Imipramine chronic treatment up-regulates 5-HT_{1A} receptor in rat hippocampus membranes

A Gomez[1], I. Bellido[2], F. Sanchez de la Cuesta[2] *[1]Department of Anaesthesia, Hospital Clínico Universitario de Málaga; [2]Department of Pharmacology and Clinical Therapeutics, School of Medicine, University of Málaga, Spain*

5-hydroxytriptamine receptor subtype 1A (5-HT_{1A}) in the rat hippocampus appears to be implicated in the psychopharmacological effects of the antidepressant imipramine (1). Our aim was to determine the possible changes in 5-HT_{1A} receptor characteristic in rat hippocampus in response to both acute and chronic imipramine administrations.

Materials and Methods: 28 male wistar rats were injected with saline or imipramine (10.9 mg/kg i.p.) acutely (three times/day × 1 day) and chronically (one time/day × 20 days). 5-HT_{1A} receptors were characterised with (^3H)-8-OH-DPAT saturation experiment according to the methods of Pazos et al (2) in membranes from hippocampus. Binding data were analysed using Ligand software Results were analysed by ANOVA test followed by Bonferroni post-test

Results: The affinity of (^3H)-8-OH-DPAT for 5-HT_{1A} receptors were in a similar range in all studied groups. Acute treatment with imipramine did not modified 5-HT_{1A} receptor density. Chronic treatment with imipramine significantly increased (38.18%) ($P < 0.01$) the density of 5-HT_{1A} receptors (427 ± 50 fmol/mg of protein and 309 ± 22 fmol/mg of protein, imipramine and control, respectively)

Conclusion: Chronic treatment with imipramine up regulated 5-HT_{1A} receptors in rat hippocampus membranes. This event could be related with its analgesic effect in chronic pain.

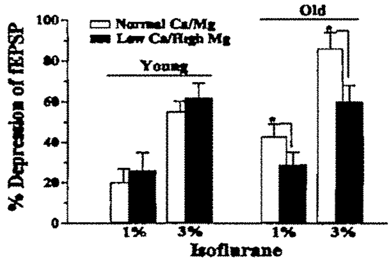
A.356 Low extracellular Ca^{++}/Mg^{++} ratio opposes anaesthetic actions on old hippocampal neurones

Hossam El-Beheiry[1], Aviv Ouanounou[2], Peter L Carlen[3]. *Playfair Neuroscience Unit, The Toronto Hospital Research Institute, Departments of [1]Anaesthesia; Medicine [3](Neurol.) and [2]Physiology, University of Toronto, The Toronto Hospital, Western Division, 399 Bathurst Street, Toronto, Ontario, Canada M5T 2S8*

Background and Goal of Study: Preliminary studies showed that ageing enhances anaesthetic-induced depression of the evoked dendritic field excitatory postsynaptic potentials (fEPSP) without any effect on the presynaptic volley in hippocampal slices[1] We hypothesized that a presumed ageing-induced increase in $[Ca^{2+}]_i$ may lead to the observed enhanced vulnerability of old hippocampal neurones to isoflurane actions To investigate this assumption, we recorded evoked fEPSPs in young and old hippocampal slices during perfusion with normal perfusate and low Ca^{2+}/high Mg^{2+} medium. The latter manoeuvre is known to reduce $[Ca^{2+}]_i$.

Materials and Methods: Hippocampal slices (400 μm thick) were prepared from Old (~24 months) and young (~3 months) Fisher 344 rats. fEPSP were evoked by stimulation of stratum radiatum and were recorded extracellularly at the dendritic field of the CA1 neurones. In a submerged recording chamber, slices were randomly incubated and perfused at 35°C with normal perfusate containing 2 mM Ca^{2+} and 2 mM Mg^{2+} or low Ca^{2+} (1 mM)/high Mg^{2+} (3 mM) medium before application of isoflurane.

Results and Discussion: In normal perfusate, the magnitude of isoflurane suppression of fEPSPs was greater in slices taken from old rats compared to those taken from young rats During perfusion with low Ca^{2+} high Mg^{2+} medium, subsequent application of isoflurane depressed the fEPSPs in young slices to the same extent as in aged slices (cf Figure; * indicates $p < 0.05$, Mann-Whitney U-test)



Conclusion: We conclude that decreasing $[Ca^{2+}]_o$ reverses the ageing-induced potentiation of isoflurane actions Therefore, the increased sensitivity of excitatory synapses of aged hippocampal neurones to anaesthetic actions might be due to a sustained rise of $[Ca^{2+}]_i$ associated with ageing

A.357 Markers of neuronal injury during liver transplantation: a preliminary report

S E Bakewell, B F Matta, J Klinck, K E. Gunning *Department of Anaesthesia, Addenbrooke's Hospital, Hills Road, Cambridge, CB2 2QQ, UK*

Background and Goal of study: Neurological complications contribute significantly to morbidity and mortality associated with liver transplantation [1]. S100 and neuron-specific enolase (NSE) are proteins which indicate neuronal injury after ischaemic stroke, intracerebral haemorrhage, minor head injury [2] and cardiopulmonary bypass [3] The serum concentrations of these proteins correlate with outcome We investigated these markers in 5 patients during liver transplantation.

Materials and Methods: With Local Ethics Committee approval, 5 patients (ASA IV–V, age 30–65) scheduled for liver transplantation were recruited. All patients received a standardised general anaesthetic. Blood samples were taken post-induction (A), at the beginning (B) and end (C) of the anhepatic phase, and at skin closure (D). The samples were immediately centrifuged and the plasma frozen at −60°C. Plasma concentrations of S100 and NSE were analysed using an immunoluminometric assay. Neurological status, liver and renal function were assessed preoperatively and postoperatively

Results and Discussion: Results are shown in Table 1. There was no significant change in NSE levels S100 levels increased significantly during liver transplantation.

Table 1

Patient	A	B	C	D
1	0 09	0 28	0 36	0 96
2	0 17	0 31	0 58	0 73
3	0 21	0 37	1 25	0 46
4*	6 15	3 19	4 16	2 75
5	0 22	0 94	0 67	0 64

S100 levels in mcg/l *Patient in hepatic encephalopathy

Conclusions: Plasma concentrations of S100 increase during liver transplantation The values are markedly elevated in encephalopathy The use of S100 as a marker of neuronal injury during liver transplantation warrants further investigation

LOCAL AND REGIONAL ANAESTHESIA

A.358 Lignocaine + clonidine *vs* lignocaine + bupivacaine: comparison in peribulbar anaesthesia

T Gillart, F Bevillard, J.M Constantin, I. Houtman[1], J.E. Bazin, P. Schoeffler *Departments of Anaesthesiology and [1]Ophtalmology University Hospital, 63003 Clermont Ferrand, France*

Introduction: The purpose of this study was to compare the effects of clonidine or bupivacaine on akinesia and haemodynamic status during peribulbar anaesthesia for cataract surgery

Methods: After informed consent and institutional approval, 100 patients, scheduled for ophtalmic surgery, were included. A two injection sites technique was used by the same experimenter followed by mechanical orbital compression for 10 min. The anaesthetic mixture was administered at constant speed with a pump (12 ml/min), at room temperature, without adjustment of pH. The patients were randomly divided into two groups which received 6 ml lidocaine 2% + 6 ml bypivacaine 0 5% in group **B** (n = 50), 11.5 ml lidocaine 1% + 75 g clonidine in group C (n = 50), each + 250 UI hyaluronidase Efficacy of the block was assessed 10 min after injection (ie after compression) by an independent observer, according to the degree of residual movement akinesia of extraocular muscle was scored good for less than 2 mm eye movement vertically or horizontally, akinesia of orbicular muscles was scored good for complete akinesia or slight movement in either or both eyelid margins. The need for reinjection or not was left to the surgeon to decide Arterial pressure, heart rate and capillary oxygen saturation were measured non invasively before the block, after injection and every 10 min during surgery The two groups (Gaussian distribution) were compared using chi-square test and Student t test A P value < 0.05 was considered significant.

Results: Groups B and C were comparable for the variables of sex, age, weight and axial length of the eye No significant difference was found concerning extraocular and orbicular muscle akinesia (Fig. 1) After preoperative reinjection of 6 to 8 ml when necessary all the operations took place under satisfactory condition In all cases analgesia was satisfying. The haemodynamic profiles measured were similar between the two groups but 7 patients in group B vs 0 in group C presented an episode of hypertension above 200 mmHg systolic value, requiring specific treatment No SpO2 lower than 94% was found

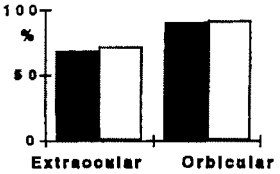

Fig 1 percentage of good akinesia

Conclusion: This randomized study shows that adding clonidine to lidocaine 1% is a good alternative to bupivacaine An equivalent quality motor block is obtained, combined with better haemodynamic stability.

A.359 Effect of volume and speed of injection of local anaesthetics on akinesia during peribulbar block

T. Gillart, G Gindre, F. Bevillard, I Houtman[1], J E. Bazin, P Schoeffler *Departments of anaesthesiology and [1]Ophtalmology University Hospital, 63003 Clermont Ferrand, France*

Introduction: The purpose of this study was to evaluate the effect of the volume and the speed of administration of local anaesthetics on akinesia after peribulbar anaesthesia for ophthalmic surgery

Methods: After informed consent and institutional approval, 100 patients (ASA I, II, III), scheduled for cataract surgery, were included in this study A two injection sites technique was used by the same experimenter followed by mechanical orbital compression for 10 min A mixture of 50% bupivacaine 0.5%, 50% lidocaine 2% and 250 UI hyaluronidase was administered at room temperature, via low compliance tubing, with a pump (Becton Dickinson). The patients were randomly divided into 4 groups (n = 25): group *A* received 3 ml at the upper site and 6 ml at the lower site at a speed of 5 ml min^{-1}; group *B* received the same volumes at a speed of 12 ml min^{-1}, group *C* received 4.5 ml at the upper site and 9 ml at the lower site at a speed of 5 ml min^{-1}; group *D* received the same volume as group C at a speed of 12 ml min^{-1} Efficacy of the block was assessed 10 min after injection (ie after compression) by an independent observer, according to the degree of residual movement akinesia of extraocular muscle was scored good for less than 2 mm eye movement vertically or horizontally, akinesia of orbicular muscle was scored good for complete akinesia or slight movement in either or both eyelid margins. Additionally, injection pain was assessed by questioning the patients and scored from 0 to 3 according to whether it was negligible (0), low (1), moderate (2), or required to stop the injection (3) The four groups (Gaussian distribution) were compared using chi-square test and ANOVA method. A *P* value < 0 05 was considered significant

Results: The 4 groups were comparable for the variables of sex, age, weight and axial length of the eye Concerning extraocular muscles a significant difference was found between group D, and groups A, B, C No statistical difference was noted concerning the pain scores obtained in each group. No patient suffered such pain that the protocole had to be discontinued No side effect was noted during the observation period

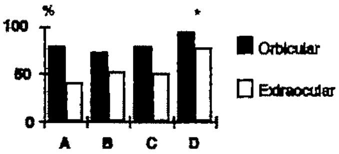

Figure 1 percentage of good akinesia

Conclusion: The quality of akinesia after peribulbar anaesthesia depends on both the volume and the speed of administration of local anesthetics. The best results are obtained with a large volume (13 5 ml) and the higher speed of administration (12 ml/min). These are well tolerated

A.360 Sub-Tenon's *vs* retrobulbar anaesthesia for cataract surgery

C.L.G Rutten, K F Tjia, M.J M. Gielen *Weezenlanden Hospital, Zwolle, The Netherlands*

Background and goal of the study: The effectiveness and safety of the sub-Tenon's anesthesia in ocular surgery has been described (1, 2) In this study sub-Tenon's and retrobulbar anesthesia for cataract surgery in outpatients are compared.

Materials and Methods: Sixty patients undergoing cataract surgery on both eyes, within six months of each other, were divided into two random groups. One group of thirty patients received sub-Tenon's anesthesia for the first procedure and retrobulbar for the second. The other group received first retrobulbar anesthesia and sub-Tenon's for the second procedure.

The local anesthetic consisted of a 4 ml injection of a 1·1 mixture with lidocaine 2%, bupivacaine 0 5% and hyaluronidase without epinephrine. After injection ocular pressure was applied for 20 min No premedication, van Lint block or i v. sedation were used.

Twenty minutes after the injection the anesthetist and the surgeon evaluated independently the effectiveness of the anesthesia Patients' satisfaction with the anesthesia and operation was evaluated by using a standard oral questionnaire

Results and discussion: There was no statistical difference between the groups in respect to age, sex, and time between the two operations. Both techniques had similar anesthetic properties There were no anesthetic or surgical complications recorded

In the patients' view the retrobulbar injection caused more pain and discomfort in comparison with the sub-Tenon's injection. After the patients had experienced both of the anesthetic techniques 36 out of 60 preferred sub-Tenon's and only 11 retrobulbar anaesthesia

Conclusions: Sub-Tenon's anesthesia technique is safe and effective for patients undergoing cataract surgery It has proved to be significant less painful procedure compared to retrobulbar anesthesia. The questionnaires confirm that patients feel more comfortable with sub-Tenon's anesthesia

A.361 Haematoma frequency in peribulbar anaesthesia

H. Kallio, M Paloheimo, E.-L. Maunuksela *Helsinki University Central Hospital Eye Hospital, Helsinki, Finland*

Introduction: The patient population coming for intraocular surgery commonly uses aspirin to inhibit platelet aggregation or nonsteroidal anti-inflammatory drugs (NSAID) or needs warfarin for anticoagulation Retrobulbar high pressure haematoma postpones the planned eye operation and may cause compression of the circulation and ocular nerve and lead to permanent blindness of the eye. Because of this it is important to avoid peribulbar haematomas as far as possible. Patients are advised not to take warfarin for two days and aspirin for three days before surgery. Anyhow, many patients disobey these orders.

Methods: 1150 consecutive patients coming for eye surgery requiring peribulbar block, were interviewed about their use of aspirin, NSAID and warfarin. Diabetes mellitus, use of systemic cortisone and doctors estimate for the relation between orbita and bulbus (1–3) was registered. The appearance and the size of the possible haematoma was evaluated as. 1 = spot haematoma, 2 = half or less around the eye, 3 = all round the eye, but no pressure, 4 = retrobulbar haematoma with pressure Fisher exact test was used to evaluate the significance of the results.

Results: Warfarin was used by 6.1%, aspirin by 35.7% and NSAID by 20.2% of the patients Warfarin, aspirin and NSAIDs did not predispose to haematomas The frequency of haematomas was 4.1% and 55.3% of these were minor spot haematomas. No high-pressure retrobulbar haematomas were induced. There were no statistical difference between staff anaesthesiologists and doctors in training in the haematoma frequency (3 7% vs. 5.6%). 33.8% of the patients reported to have haematoma tendency, but this did not affect the incidence. The anatomical distance between orbita and bulbus, diabetes mellitus or cortisone-treatment did not increase haematoma frequency.

Conclusion: In the practice of our department there is no indication to limit the patients use of aspirin or NSAIDs. It is recommended to make sure that the warfarin anticoagulation is not over the therapeutic level.

A.362 A retrospective review of 7235 consecutive regional anaesthetics for cataract surgery

M Granell, M.R. Tommasi, Y Perez, R García-Aguado, G Muñoz, T. Sánchez, A. Rodriguez, F. Grau. *Hospital General Universitario, Hospital de Valencia al Mar, Valencia, Spain*

Background & Goal of Study: The basic goals for successful anaesthesia in ophthalmic surgery include anaesthesia of the eye, akinesia of the external eye muscles, and low intraocular pressure. Use of regional and local anaesthesia for cataract surgery provide excellent anaesthesia and operating conditions, and may be safe in elderly outpatients, who frequently exhibit several coexisting diseases We report a retrospective study of 7235 consecutive regional anaesthetics for cataract surgery performed between September 1995 and September 1997

Material & Methods: In the last two years 7235 patients underwent ambulatory elective cataract extraction and intraocular lens implantation. All blocks were performed using local anaesthetic mixture (0.75% bupivacaine and 2% lidocaine with 1:100.000 adrenaline) and 150 IU hyaluronidase. The total volume of the local anaesthetic was 10 ml. For peribulbar anaesthesia, modified technique described by Fry and Henderson was used, and the depth of the injection was 20–25 mm, avoiding the muscle cone For retrobulbar block, 4 ml was injected into the muscle cone through the inferolateral lower lid entry. Local anaesthesia was too performed with topic application of lidocaine. In all patients, a mechanical orbital compression device (pressure, 40 mmHg) was then applied for 15 minutes to reduce intraocular pressure.

Results: Peribulbar anaesthesia was performed in 40.1% of patients, retrobulbar block in 54.9% and topic anaesthesia in 4.8%. As complication of our casuistic, we registered in 19 patients retrobulbar haemorrhages (in 5 cases surgery was suspended), in three patients occurred globe perforation (two of them with retrobulbar needle); acute pulmonary oedema was found in 2 patients (they were admitted in intensive care unit). The oculocardiac reflex was found in six patients. In 3 cases we had apnea following retrobulbar block, and one patient presented intraoperative seizures, with the need of tracheal intubation The mean time of observation in the recovery room was 120 minutes, and thereafter all patients could be discharged.

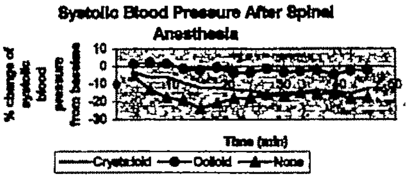
Conclusions: Satisfactory akinesia and analgesia for cataract surgery can be produced using regional block, with fewer serious complications and it is relatively easy to perform for anaesthesiologists well experienced with regional methods.

A.363 Prevention of hypotension after spinal anaesthesia for elderly patients: a comparison of intravascular administration of crystalloid, colloids and no prehydration

S Esin Lekili, Yasemin Karcioğlu, Işıl Eren *SSK Tepecik Educational Hospital, Anesthesiology and Reanimation Department, Izmir, Turkey*

Background and Goal of Study: Hypotension after spinal anesthesia for elderly patients remains a common and potentially serious complication. A growing number of clinical studies have shown that there was no realistic policy in preventing spinal anaesthesia-induced hypotension although prehydration may reduce the incidence of hypotension (1, 2) The present study aimed to investigate the influence of volume loading with crystalloids, colloids versus no prehydration on the spinal anaesthesia-induced haemodynamic changes in patients undergoing orthopaedic surgery

Materials and Methods: The study was conducted on 45 patients (mean age 54, ASA I–II) after local ethic committee approval was obtained In the supine position a baseline systolic blood pressure (SBP), heart rate (HR) and central venous pressure (CVP) were recorded. Patients randomly allocated into 3 groups. Group 1 (n = 15) received 500 cc normal saline 0.9%, group 2 (n = 15) received 500 cc 6% hydroxyethyl starch over a 10 minute-period before the spinal anaesthetics. Group 3 (n = 15) received no significant prehydration. Spinal anaesthesia was performed in the lateral decubitus position at the L_3–L_4 interspace with a 22G needle using 3 ml of bupivacaine 0.5%. All the patients were given a crystalloid infusion at 100–150 ml/h during the surgery. SBP, HR and CVP were measured at 3-minute intervals for 45 minutes. When SBP decreased to less than 75% of the baseline value, 3 mg of ephedrine was administered.



Results and Discussion: After spinal anaesthesia, the average of SBP decreased 11% in crystalloid group, 2% in colloid group and 16% in nonprehydrated group ($p < 0.001$). The patients requiring ephedrine 20% in group 2, 29% in group 1, 66% in group 3. Incidence and frequency of ephedrine use and mean doses were lower in the group 1 and group 2 than group 3 ($p < 0.05$). CVP decreased 2% in group 1, 7% in group 3 and increased 3% in group 2 ($p < 0.001$). There was no difference between group 1 and group 2 ($p > 0.05$), but group 3 was significantly lower than the other groups ($p < 0.05$) HR values were similar.

Conclusion: We concluded that prehydration with crystalloid or colloid are warranted for spinal anaesthesia-induced hypotension.

A.364 Cardiovascular effects of crystalloid and colloid solutions during spinal anaesthesia

P. Marhofer, B. Faryniak, C Oismuller, S Kapral, N. Mayer. *Department of Anesthesiology and General Intensive Care Medicine, University of Vienna, A-1090 Vienna, Austria*

The ideal fluid regimes for patients scheduled for spinal anesthesia is discussed controversial. Particular in elderly, multimorbid patients the advantages and disadvantages of crystalloid and colloid solutions have to be weighed carefully. Also the cardiovascular effects during spinal anesthesia are researched in healthy young volunteers or in animals The present study was designed to comparatively analyze crystalloid and colloid fluid regimes in terms of hemodynamic responses by using invasive hemodynamic monitoring

Methods: After institutional ethic committee approval and informed consent 24 ASA II–IV patients undergoing hip surgery following trauma were enrolled for the study Hemodynamics were recorded with a pulmonary artery catheter, an ECG and an arterial line. Group A received 500 mL hetastarch 6% and group B 1500 mL lactated Ringer's solution Following fluid administration spinal anesthesia was conducted with 3 mL bupivacaine 0.5%. Hemodynamics were recorded prior to fluid administration, before spinal puncture and 10, 20 and 30 min following spinal puncture Hypotension was defined as a decrease of mean arterial pressure to less than 70% of baseline value Intraoperative blood loss was measured exactly. Statistical analysis were performed by paired and unpaired Student t-test and by ANOVA for repeated measures with Bonferroni correction A p < 0 05 was considered significant.

Results: We found no significant differences in demographic datas, analgesia level and intraoperative blood loss between the study groups. We observed hypotension in one patient in group B Heart rate, cardiac index and right ventricular end-diastolic volume index remained stable during the study period. Systemic vessel resistance index decreased significantly in group B (−18 ± 7% and −20 ± 12% from baseline 20 and 30 min after spinal puncture). The almost identical increase of wedge pressure following fluid administration demonstrates the employment of equieffective fluid regimes in this study (Figure)

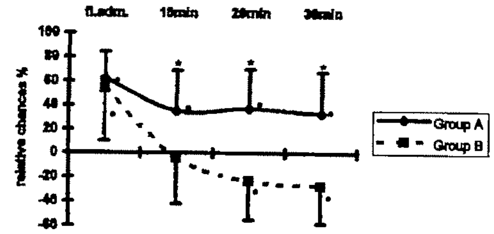

Table. Relative changes in wedge pressure after fluid administration, 10, 20 and 30 min after spinal puncture. *p < 0 01 between and °p < 0 05 insider the study groups

Conclusion: A single Infusion of hetastarch 6% (8.3 ml/kg in our study) prior to spinal puncture compensates hemodynamic effects during spinal anesthesia. Cardiovascular reactions after spinal anesthesia are only caused by a decrease of peripheral resistance and not by cardiac output.

A.365 Effects of preloading with NaCl 0.9%, HES (450/0.7) 6% and NaCl 3% on haemodynamic changes and serum osmolality in patients undergoing TURP under spinal anaesthesia

I Karabeyoğlu, N Goğüş, T. Gumüş, H. Gumuş, S Deren, O Cuvaş, C Aksu *Department of Anaesthesiology and Reanimation, Numune Hospital, Ankara, Turkey*

Introduction: Fluid preloading is a commonly used method to prevent the hypotension during spinal anaesthesia In this study, we compared the effects of 0 9%NaCl, 6%HES and 3% NaCl given as a preload in maintaining haemodynamic stability in patients undergoing transurethral resection of the prostate (TURP) under spinal anaesthesia

Methods: After obtaining local hospital Ethics Committee's approval and informed consent, 36 male patients (ASA I–III) were randomly allocated to three groups Patients in each group were given 0.9%NaCl (2 meq/kg), 6% HES (7 ml/kg) and 3% NaCl (2 meq/kg) as preloading fluid before spinal anaesthesia, respectively Heart rate (HR), Mean arterial pressure (MAP) were measured by datascope and central venous pressure (CVP), cardiac index (CI), end-diastolic index (EDI) and systemic vascular resistance index (SVRI) were measured noninvasively by transthoracic electrical bioimpedance (TEB), and measurements were recorded before preloading (control), and 1, 5, 10, 15, 20, 25, 30, 45 and 60 minutes after preloading

Osmolality was calculated using the Na^+, K^+, blood glucose and BUN values measured before preloading and 1, 30 and 60 minutes after preloading. Statistical significance was determined by Student's t test

Results: There was no significant difference between three groups regarding HR, CI and SVRI values. CVP, MAP and EDI were higher in the 6% HES and the 3% NaCl groups compared with the 0 9% NaCl group (p < 0.05) While serum Na^+ and osmolality decreased at 30 and 60 minutes in the 0 9% NaCl group and at 60 minutes in the HES group, there was no decrease in the 3%NaCl group

Conclusions: We conclude that HES and 3% NaCl can be used as a safe preloading agents in patients undergoing spinal anaesthesia in maintaining cardiovascular stability. 3% NaCl can also decrease the risk of dilutional hyponatremia seen in TURP procedures

A.366 Puncture technique and postural post-dural puncture headache

H. Flaatten[1], T Thorsen[1], B. Askeland[1], M. Finne[1], J. Rosland[2], K. Rønhovde[3], T. Wisborg[3]. [1]*Dep. of Anaesthesiology, University Hospital of Bergen;* [2]*Vest Agder Central Hospital and* [3]*Hammerfest Hospital, Norway*

Background: The study was conducted in order to investigate the effect of the orientation of the bevel during dural puncture on the occurrence of PPDPH using a 0 42 mm (27 g) Quincke needle

Materials and Methods: 199 patients, aged 18–50 years, scheduled to non-obstetric infraumbilical surgery using spinal anaesthesia (SA) were included in the study The study was approved by the regional ethical committee, and informed consent from each patients was obtained in advance Patients were block randomized into two groups· A *parallel* group (with orientation of the bevel during dural puncture parallell to the longitudinal dural fibers) and a *perpendicular* group (orientation 90° angle to the fibers) Dural puncture were performed using a midline approach, with the patients usually in the lateral semiflexed position In all patients a 0.42 mm (27 g) Quincke needle (Braun or BD) was used. Anaesthetic agent was selected according to the anticipated length of surgery, using either hyper- or isobaric lidocaine or bupivacaine

Patients were blinded to the puncture technique, and so was an anaesthesiologist performing a telephone interview 5–7 days postoperatively. Using a semi structured interview the patients were asked about postoperative complaints in general, and headache and backache in particular PPDPH was defined as headache occurring postoperatively, usually after mobilization, relieved by lying down and aggravated when sitting or standing. Intensity of PPDPH and non-PPDPH was measured using a numeric rating scale from 1–10 (1 being no pain and 10 the worst pain imaginable)

Results: 194 patients were fully evaluable The reason for exclusion from the study are· Unable to contact postoperatively n = 2, no CSF found during dural puncture (patient given general anaesthesia) n = 1, one patients denied participation after randomization and one SA given by a trainee.

Mean age of the patients was 35 2 years. The two groups were comparable regarding age, sex, operating procedures performed, operating time and use of local anaesthetics PPDPH occurred in 4/97 (4 1%) in longitudinal group compared to 22/97 (22 6%) in the perpendicular group (p = 0.0007 Chi Square test) The 95% confidence interval of difference in PPDPH (18 6%) between the groups are 9 3–27 8%

Non-PPDPH occurred in 8 and 7 patients and backache in 28 and 18 patients (longitudinal compared to perpendicular group, NS)

Conclusions: When using Quincke needles orientation of the bevel is an important risk factor for the development of PPDPH even with small diameter needles. When using such needles care must be given to assure that the orientation of the bevel is parallell to the longitudinal dural fibers during dural penetration.

A.367 Unilateral spinal anaesthesia. Effects of needle design

A Casati, G Fanelli, G Aldeghen, G.L Cappellen, M Berti, G. Torri *University of Milan, Dept of Anaesthesiology IRCCS H San Raffaele, via Olgettina 60, 20132 Milan, Italy*

Background: In a search of an asymmetrical spinal block between surgical and non-surgical sides, we evaluated in a double-blind fashion the influence of needle tip on lateral distribution of hyperbaric bupivacaine in 30 patients scheduled for one leg surgery.

Methods: Patients were placed in the lateral position with the operated side dependent; then they were randomly allocated to receive 8 mg of 0 5% hyperbaric bupivacaine injected over 30 sec through a 25-gauge Whitacre (Whitacre, n = 15) or Quincke (Quincke, n = 15) spinal needle (Becton-Dickinson, New Jersey, USA) Before injecting the local anaesthetic solution, the needle bevel was turned toward dependent side of spinal canal Lateral position was maintained for 15 min. A blind observer recorded the progression of sensory and motor blocks on both sides The presence of an adequate sensory and motor block on surgical side, without one or both blocks on non-surgical one was considered as unilateral spinal anesthesia. Mann-Whitney test and Fisher exact test were used as indicated A value of P < 0 05 was considered as significant.

Results: Only one patient in Quincke group required general anesthesia due to inadequate spinal block (P > 0.05). Main results are presented in the table

	Whitacre (n = 15)	*Quincke* (n = 15)
Unilateral sensory block	10 (66%)	2 (13%)[$]
Unilateral motor block	11 (73%)	6 (40%)

[$] P < 0 01 vs Whitacre

Sensory block was 20% longer on operated side in 11 and in 8 patients respectively in Whitacre and Quincke groups (P > 0.05), while motor block was 20% longer on operated side in 13 and in 12 patients respectively in Whitacre and Quincke groups (P > 0 05),

Conclusion: When low dose of 0 5% hyperbaric bupivacaine and low speed of intrathecal injection are used in patients lying lateral for 15 min, Whitacre spinal needle allows a more marked differential block of sensory nerve roots between surgical and non-surgical sides as compared to Quincke needle

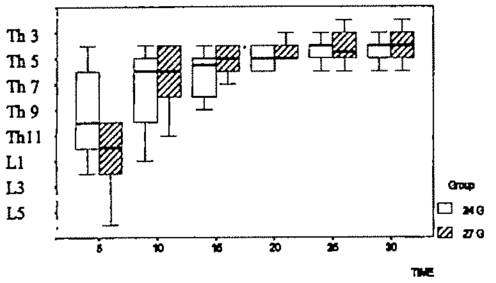
A.368 Spinal local anaesthetics distribution with two different pencil-point needles

N Vervloesem, C. Mardirosoff, L. Dumont, M. Wolfs. *Brugmann University Hospital, Brussels, Belgium*

Background and Goal: Small gauge spinal pencil-point needles may lead to local anaesthetics maldistribution if injection is made in the caudal direction and if the injection speed is too slow (1). The purpose of this study was to evaluate the clinical distribution of local anaesthetics when injection was performed at a high rate and in a caudal direction through two different gauge pencil-point needles

Materials and Methods: After ethic committee approval and verbal patient consent, 20 ASA I or II patients scheduled for orthopaedic surgery of the lower limbs were randomised in two groups The two groups received a standard infusion line with Ringer-lactate solution. All patients were monitored using a single lead ECG, SpO_2 and NIBP during the procedure Spinals were performed in a sitting position at the L2–L3 interspace We injected 3 ml (15 mg) hyperbaric bupivacaine in a caudal direction in 10 seconds in both groups. We used a $27G3^{1/2}$ Whitacre needle for one group and a 24 G Sprotte needle for the second group. Patients in both groups were placed supine four minutes after spinal injection Sensory block levels were measured with ether in the midline at 5, 10, 15, 20, 25 and 30 minutes after spinal injection Hypotension, as defined by a 20% decrease from baseline or by a systolic blood pressure below 100 mmHg, was treated with ephedrine, atropine or phenylephrine according to the heart rate.

Results: The two groups were demographically comparable. Median sensory block levels at 30 minutes were at Th 4 in both groups (see figure)



Conclusions: Our study shows that spinal local anaesthetics distribution at a fast injection rate and in a caudal direction is uniform with a 27 G Whitacre needle compared to a 24 G Sprotte needle

A.369 Advantage of multiple nerve stimulation in the axillary brachial plexus block

J Pascal, C. Michard, R Allary, S. Molliex, C. Auboyer *D.A.R. Hopital Bellevue, CHU St Etienne, 42055 St Etienne cedex2, France*

Background & Goal of Study: The axillary approach to brachial plexus is the most popular for hand and forearm surgery The use of multiple stimulation approach improve the successful rate of axillary brachial plexus block (ABPB). However this technique has been principally evaluated by experienced anaesthetists working in hand surgery units (1). The aim of this study was to assess the success rate of ABPB according to the number of nerve stimulation and to the physician experience in a non hand surgery specialized center.

Materials & Methods: 287 brachial plexus blocks, between dec 94 and dec 96, were retrospectively studied. 209 ABPB were performed for hand and forearm surgery by experienced physician and by resident. Neural block was realised using a 22G insulated 50 mm bevelled needle and a peripheral nerve stimulator (Stimuplex, B Braun Medical). By axillary approach, one, two or three nerves (median, ulnar, radial, musculocutaneous) were located and blocked. The musculocutaneous nerve was never blocked alone. All patients received, in one or more injections, a total of 30 ml to 50 ml of lidocaine 1.5% with epinephrine 1:200 000 for the block. For each nerve, the stimulation eliciting muscle contraction was equal or less than 0.5 mAmp ABPB was considered unsuccessful if general anaesthesia or supplemental peripheral nerve block were required. Statistical analysis consisted of the χ^2 test and bilateral Fisher's exact test for qualitative variables. A p value < 0.05 was considered significant.

Results & Discussion: There were no differences in demographics data between groups No complications were noted The overall successful rate was 64.6% (135/209) and increased regarding the number of nerve stimulation (table). When physician experience was taken into account, the number of stimulation remained an important factor of success as show in table.

Nerve blocked	Success	Resident	Physician
One	48 3% (28/58)	41 9% (13/31)	55 6% (15/27)
Two	67% (61/91)	51% (24/47)	84% (37/44)
Three	76 7% (46/60)	70 4% (19/27)	81.9% (27/33)

Conclusion: Our study demonstrate that the success rate of ABPB increase with the number of stimulation independently of physician experience This approach of ABPB should be develop particularly in teaching hospital.

A.370 Effects of surgical position on pulmonary function in patients with diaphragmatic paresis due to interscalene brachial plexus block

X Sala-Blanch, L Edo, M. Vargas, R Masià,. J. Correa. *Department of Anesthesia, Hospital de Sant Boi, Sant Boi del Llobregat, Spain*

Background and Goal of the Study: Surgical procedures of shoulder may be performed in different surgical positions We studied the effects of position on ventilatory function in patients with diaphragmatic paresis due to interescalene brachial plexus block (IBPB)

Materials and Methods: After informed consent, 6 ASA I patients scheduled for upper extremity procedures The patients were not premedicated and IBPB was performed after localization with an electrical nerve stimulator Forty ml mepivacaine 1.5% was injected. All patients were studied in 3 different positions, the order of each position was randomised, (sitting – Si, supine – Su, and lateral – La). Spirometry was performed before (T0) and 10 minutes after the block (T1), in two subsequent efforts in each position We measured forced vital capacity (FVC) and forced expiratory volume in first second (FEV1). Respiratory rate (RR) and SpO2 were also recorded. The parameters were compared using the Wilcoxon signed rank test

Results: The mean age, height and weight were 38 ± 11 years, 168 ± 5 cm and 74 ± 7 kg respectively. The table shows the mean ± S.D. values of FVC, FEV1, RR and SpO2.

		FVC (ml)	FEV1 (ml)	RR (b/min)	SpO2 (%)
Si	T0	2762 ± 219	2188 ± 153	15 ± 2	97 ± 1
	T1	$1883 \pm 427^{*}$	$1730 \pm 426^{*}$	19 ± 5	95 ± 1
Su	T0	2523 ± 252	2105 ± 151	14 ± 2	97 ± 1
	T1	$1323 \pm 406^{*+}$	$1088 \pm 259^{*+}$	18 ± 6	$95 \pm 1^{*}$
La	T0	2543 ± 253	2077 ± 148	15 ± 2	97 ± 1
	T1	$1518 \pm 606^{*+}$	$1203 \pm 407^{*+}$	$19 \pm 2^{*}$	96 ± 2

* $p < 0.05$ with respect T0, $^{+}$ $p < 0.05$ with respect Si.

The table shows that mean values for FVC and FEV1 were significantly higher in the sitting position on T1 compared with the supine and lateral positions.

Conclusion: This suggest that sitting position may be the best surgical position during shoulder procedures under interscalene brachial plexus block.

A.371 Superficial microcirculatory effects of interscalene plexus block

S Lehtipalo[1], L.-O D. Koskinen[2], J. Kolmodin[1], G. Johansson[1], B Biber[1]. *Departments of Anesthesiology and [1]Intensive Care and [2]Neurosurgery, Umeå University Hospital, Umeå, Sweden*

Background and Goal of the Study: The excellent motor and sensory block by interscalene brachial plexus block is well described, but few data are available on the associated sympathetic blockade. The purpose was to analyze micro-circulatory events attributable to changes in sympathetic vasoconstrictor tone.

Materials and Methods: Eight patients (age 38–65; ASA I–II; seven male and one female) scheduled for acromioplasty under standardized anesthesia were studied. A unilateral interscalene plexus catheter was inserted preop. into the perivascular sheath, using the technique described by Winnie At the end of anesthesia, all patients received bupivacain as a bolus (1.25 mg/kg) followed by a continuous infusion (0 25 mg/kg/h) for postoperative analgesia. Three descriptors were used for the evaluation of sensory (sharp, blunt and dull) and motor block (normal movements, partial block and total block). Superficial blood flow (BF) was assessed by noninvasive laser Doppler (Periflux PF4001, Perimed, Sweden) and a probe (PF 408, Perimed, Sweden), placed at the skin on the index fingers of both arms Blood flow responses to apnea (APN, at end-inspiration after a deep breath), local index finger heat provocation (HP, probe heater PF 206, Perimed, Sweden) and skin temperatures were determined.

Statistics: 2-way ANOVA and Tukeys HSD test were used for comparisons between the arms.

Results and Discussion: Interscalene brachial plexus block showed an almost complete sensory and motor block In the following respects did observations in the *blocked arm* significantly differ from those in the un-blocked arm (data shown for 0, 2 and 4 hours respectively) a) baseline BF was higher (by 350%, 265% and 165% resp), b) the increase in BF by HP was reduced (by 166%, 145%, 175% resp), c) APN induced a less pronounced decrease in BF (by 32%, 32% and 41% resp.) and, d) skin temperature was higher (by 5 7 ± 0 4, 6 7 ± 0 7° and 5 0 ± 0.7°C resp.).

Conclusions: Interscalene brachial block, besides producing sensory and motor block, increase superficial blood flow, skin temperature and reduce the regional circulatory effects to apnea after a deep breath and to heat provocation. We suggest, that this reflects a reduced neurogenic vascular tone and, as regards the latter observation, a reduced local vasodilatory reserve on the blocked side The laser Doppler flowmetry technique appears to be a useful tool for studying the sympathetic blockade following regional anesthesia

A.372 Does a distal infection of the upper limb interfere with the success rate of axillary block?

O Schneuwly, M Peter, A Forster *Division of Anesthesiology, University Hospital of Geneva, Switzerland*

Background and Goal of Study: It has already been demonstrated that tissue acidosis associated with infection modifies the local anesthetic dissociation, leading to incomplete anesthesia[1] Whether the presence of a distal infection of the upper arm may influence the success rate of axillary block is unknown To examine this hypothesis, we compared the quality of anesthesia for surgery under axillary block in the presence or in the absence of a distal infection

Material and Methods: To evaluate the failure rate of regional anesthesia, the need for supplementary blockade of peripheral nerves, sedation, or general anesthesia was investigated in 25 patients with a distal infection (group A) and in 30 patients with no infection (group B) This study was retrospective and performed during a two-years period (1996–97). The radial, median, and musculo-cutaneous nerves were localized with a nerve stimulator. A mixture of 0.5% bupivacaine and 1% lidocaine (1:1) with 1 ml clonidine (0.150 mg) was injected at each localisation, with a total dose of 41 ml

Results and Discussion: There were no statistically differences between the two groups of patients, according to age (mean age = 44 in group A, 49 in group B), sex and ASA scores The results of our study are showed in the following table:

Group	Number of patients	nb (%) of patients requiring		
		additional nerve blockade	sedation	general anesthesia
Infection (A)	25	2 (8%)	1 (4%)	2 (8%)
No infection (B)	30	1 (3%)	1 (3%)	2 (7%)

Conclusion: The success rate of axillary block was identical in the two groups (80% in the groups with infection, 87% in the group without infection). The presence of a distal infection did not interfere with the quality of anesthesia in our study. These preliminary results and the rate of local complications (particularly axillary abscess) should now be confirmed by a prospective and randomized study.

A.373 Cervical plexus block for carotid endarterectomy: influence of locoregional technique

J C. Merle, K Abhay, G. Dhonneur, J X Mazoit, S Rezaiguia, P. Duvaldestin *S.A.R., Hôpital Henri Mondor, Créteil, France*

Background: Cervical plexus block (CPB) is an effective technique in carotid endarterectomy (CE). However, local anesthetic injection in this highly vascular area may be responsible for important systemic resorption and/or accidental intravascular injection We compared two local anesthetic techniques for CE: Interscalene Block (ISB) performed with only one injection and the classical CPB.

Methods: 23 ASA II–III patients undergoing CE were randomized to received either ISB (n = 12) or CPB (n = 11). The deep CPB was performed with 20 ml 0.5% of plain Bupivacaine (B) and was assisted by a complementary superficial CPB with 20 ml of 2% plain Lidocaine (L). ISB was performed under nerve stimulation control with a single injection of 20 ml of 0 5% B combined with 20 ml of 2% L Duration of injection to achieve ISB or CPB were standardized to two min. Evaluation of pain (VAS 0–100) was performed during anesthetic and surgical procedure. Additional requirement of analgesic and sedative agents were recorded Arterial blood samples were collected, before and 3, 5, 8, 10, 15, 25, 40 and 60 min. after the beginning of the block in the two group. Plasma concentration of L and B were measured by high performance liquid chromatography Pharmacokinetic parameters included peak plasma concentration (CMax) and the time to reach the peak (TMax) calculated on individual observed data Values (Mean ± SD) were compared using the Mann and Whitney U test

Results: Demographic parameters were comparable in the two groups Satisfactory pain relief was obtained in all patients No serious adverse events were noted The plasma concentrations of L and B are summarized in the table. CMax of B is significantly decreased in ISB group No significant difference was found in CMax of L between the 2 groups TMax of B and L increased in ISB group

Discussion: In our study, the AL systemic resorption of CPB is no different from results found in previous studies [1] Since systemic toxicity of LA depends of C Max but also of the speed with C Max is reached, the results or of studies suggest that ISB is probably a safe procedure

L et B plasma concentrations (Mean ± SD)

	L		B	
	CPB	ISB	CPB	ISB
C Max (μg/ml)	5 65 ± 1 86	4 84 ± 2 12	1 64 ± 0 70	1 06 ± 0 47*

A.374 Cervical plexus block with ropivacaine for carotid endarterectomy

B Loreggian, D Ruffa, P. Greco, G Crespi, M.D Centemen, S Greco, G Servadio *Dpt Anesthesiology, Intensive Care and Pain Therapy, A.S L n° 3 Busto Arsizio (Varese), Italy*

Background and Goal of Study: The use of regional anesthesia for carotid endarterectomy was first suggested to check the patient's neurologic status during carotid cross clamping Since 1984 to 1994 we had employed the technique described by Moore(1) for carotid surgery in every patient Since 1994 we have been applying a new technique, consisting of the use of an electroneurostimulating device to detect the cervical nerves(2) Recently we have employed Ropivacaine, a new anesthetic solution available in different concentrations (2–7.5–10%), presenting a duration of action as long as bupivacaine, a lower cardiotoxicity and an earlier onset of action(3) We employed 7.5% Ropivacaine for carotid surgery to assess its pharmacologic efficacy, duration of action and complications

Material and Methods: Over a 6-month period, 50 ASA I–III patients (38 males and 12 females) undergoing carotid endarterectomy were prospectively studied Average age was 69. The anesthetic block was performed upon the C_3 transverse process, injecting up to 12–15 ml of 7 5% Ropivacaine (90–112.5 mg) Paresthesias and/or muscle contractions over the C_3 nervous area, in the nape and lateral region of the neck, were searched before injection Moreover, the superficial cervical plexus block was performed using 10–12 ml of 1% mepivacaine, according to Moore's technique The intervention began 10–15 minutes after the end of the block Analgesia was evaluated by a visual analogous scale.

Results: No patient complained of trouble from elettroneurostimulation and none underwent general anesthesia for incomplete analgesia During the surgery, sedation was provided with fentanyl (0.05–0 1 mg) in 22 patients (44%), to make them more tolerant but preserving their cooperation. Analgesia lasted enough to perform the intervention even when it sometimes lasted more than 120 minutes 40 (80%) patients valued analgesia as excellent or good, 10 (20%) as sufficient, whereas anesthesia was supplemented with local infiltration in the carotid sheat with mepivacaine in 6 patients (12%). No complication due to ropivacaine itself was shown intraoperatively, 8 patients (16%) presented hypertension Other patients developed transient hypotension (8%) and bradycardia (8%), these signs were caused by surgical stimuli of carotid glomus, as they promptly disappeared after the suspension of the surgical stimulus and the administration of vagolitic and/or vasoactive drugs 5 patients (10%) developed transient dysphonia, due to the anesthetic block of the recurrent laryngeal nerve

Conclusion: 7.5% Ropivacaine has been shown to be as effective as Bupivacaine for carotid surgery, as regards duration of action and efficacy The low toxicity suggests the use of Ropivacaine instead of Bupivacaine.

A.375 Are muscle relaxants to be used in regional intravenous anaesthesia?

N. Unal, S Poçan, I. Iltar, E. Ozgencil, Y. Keçık *Ankara University, Faculty of Medicine, Department of Anaesthesia and Reanimation, Ankara, Turkey*

Introduction: This research was planned to determine and compare the effects of addition of different muscle relaxants into local anaesthetic solutions that are used in Regional Intravenous Anaesthesia (RIVA)

Method: Fifty-one patients who had undergone hand and forearm surgery were included to this research with the approval of the ethic committee. Patients were divided into 3 groups of random after motor activity was measured with a manometer at the extremity of interest Classical RIVA was performed by using 3 mg/kg 0 5% lidocaine (LA, n = 16) in group 1, 3 mg/kg 0.5% lidocaine + 50 μg/kg atracurium (LAT, n = 16) in group 2 and 3 mg/kg 0 5% lidocaine + 7 μ/kg vecuronium (LAV, n = 20) in group 3. Heart rate, blood pressure, motor activity and sensorial blockage measurements were evaluated at the 1st, 5th, 10th and 15th minutes. Touching and pain senses were scored as blockage (+) = 0 and blockage (–) = 1 at 5 different sites and the mean values were calculated. After the blood pressure and heart rate were recorded at the end of the operation, the tourniquet cuff was release. Additionally, anaesthesia quality and muscle relaxations were evaluated and scored by the surgeon The results were analyzed with ANOVA, Mann-Whitney-U, Wilcoxon, chi-square tests, $p < 0.05$ was accepted as significant

Results: There was no difference in demographic properties, initial motor activity, tourniquet pressure, tourniquet and operation duration between the groups, 1, 5, and 10 minutes after the local anaesthetic administration, there happened a significant difference in motor activity between the groups. Motor blockage was placed at the 1st minute in group LAV at the 5th minute in group LAT, at the 10th minute in group LA. No difference was determined between the groups by means of sensorial blockage The median value for touching sense in all groups became zero at the 15th minute of local anaesthesic injection. The median value for pain sense in group LA and LAT was zero at the 5th minute and in group LAV, it was zero at the 10th minute. In the surgeons' scoring, there was no difference between the groups by means of anaesthesia quality and muscle relaxtions.

Conclusion: Our result indicated that combination of muscle relaxants accelerate the motor blockage, but even in the group LA, complete motor blockage was placed while waiting for the sensorial blockage. On the other hand, combination of muscle relaxants did not provide additional comfort for the surgeon For the reasons, combination of muscle relaxants to lidocaine solution is not considered to be useful application in RIVA.

A.376 Clonidine and lidocaine *vs* lidocaine for intravenous regional anaesthesia

M. Gentili, J.-M. Bernard[1], F. Bonnet[2]. *Departments of Anaesthesia, CMC Saint-Vincent, 35760 Saint-Grégoire; [1]Polyclinique Jean-Villar, 33520 Bruges; [2]Hopital Tenon, 75020 Paris, France*

Background and Goal of the Study: As clonidine can enhance the effects of lidocaine on C-fiber action potential (1), this double-blind, randomised, study was designed to examine the effects of the addition of clonidine 150 μg to 40 mL lidocaine 0.5% for IVRA.

Materials and Methods: After informed consent and institutional approval, 24 ASA-1 patients, scheduled for minor hand surgery, were studied during an IVRA performed with a double-cuffed tourniquet. Proximal cuff was inflated first (7 cm wide; 250 mmHg) and switched to the distal cuff (7 cm wide, 250 mmHg) if the patient complained of tourniquet pain. The test drugs, i.e. either saline (n = 12) or clonidine (n = 12) at random, were injected with lidocaine in the arm after its exsanguination using an Esmarch bandage. Duration of pain tolerance, defined by the time elapsed between inflation and deflation of the proximal cuff, was measured, as well as tourniquet and forearm pains using a visual analog scale, blood pressure, heart rate and sedation, before and 15, 30 and 45 min after injections. Statistics were Mann-Whitney tests and ANOVA *P* was set at 0.05.

Results and Discussion: Duration of pain tolerance was greater in the Clonidine group (27 ± 15 *vs* 14 ± 6 min, $p < 0.01$). Tourniquet and forearm pain scores and systolic arterial pressure were greater in the saline group (Table). Systolic and diastolic arterial pressure increased only in this group ($p < 0\ 01$) There were no changes and no differences between groups for sedation and heart rate

	Before	15 min	30 min	45 min
Tourniquet pain score (0–100) *median; range*				
Saline	0, 0–0	40, 10–70	40, 20–60	50, 30–70
Clonidine	0, 0–0	20, 10–50*	25; 20–30	30, 20–40*
Forearm pain score (0–100) *median, range*				
Saline	0, 0–0	25, 0–50	30, 10–40	35; 20–50
Clonidine	0; 0–0	15, 0–20	15, 0–30*	20, 0–30*
Systolic arterial pressure (mmHg) *m ± SD*				
Saline	132 ± 6	140 ± 4	140 ± 5	141 ± 6
Clonidine	133 ± 8	135 ± 5*	137 ± 5	136 ± 6

* $p \leq 0\ 05$ comparisons between groups

Conclusion: Clonidine may improve IVRA with 0.5% lidocaine, both in terms of controlling intraoperative pains and by blunting hypertensive response to tourniquet

A.377 Is ropivacaine 0.2% an alternative to lidocaine 0.5% for intravenous regional anaesthesia?

P.G. Atanassoff, M.W.B Hartmannsgruber. *Department of Anesthesiology, Yale University School of Medicine, New Haven CT, USA*

Introduction: Intravenous regional anaesthesia (IVRA) may be used to anaesthetize the upper limb for a variety of surgical procedures Lidocaine 0.5% is most frequently used for this purpose. Recently ropivacaine was introduced and was shown to produce only minor side effects following intravenous injection (1). We investigated if ropivacaine would produce equal efficient surgical anaesthesia as lidocaine when used for IVRA.

Methods: Following IRB approval, ten healthy, unpremedicated volunteers participated in this randomized, double-blind, cross-over study receiving 40 ml of either plain lidocaine 0 5% or plain ropivacaine 0.2% for IVRA, at least four days apart Pain assessments were made using a verbal numeric scale (VNS), from 0 = no pain to 10 = worst imaginable pain in response to a 50 Hz tetanic stimulus of 60 mA. This has been shown to be an equivalent stimulus to surgical incision (2). Loss of sensation was evaluated by pinprick. Motor function was evaluated using a blood pressure cuff that was inflated to 40 mmHg and which the volunteer was asked to squeeze maximally Following exsanguination, the proximal portion of a double-cuff tourniquet was inflated to a pressure of 250 mmHg When the proximal tourniquet pressure became unbearable and was rated 10 on the VNS, the distal cuff was inflated followed by release of the proximal tourniquet The distal tourniquet remained inflated until a VNS score of 10 was reached again. Measurements were performed prior to, and every 5 min during tourniquet inflation as well as 3, 10, and 30 min (table) after release of the distal tourniquet. Following deflation of the distal tourniquet, the volunteers were questioned about CNS side effects and asked to rate them on a VNS between 0–10. Simultaneously, ECG changes from baseline were recorded. Data are expressed as mean ± SD and were analyzed using Wilcoxon rank and paired t-tests for non-parametric and parametric data, respectively; $p < 0.05$ was considered statistically significant

Results: There were no significant differences between the two local anaesthetics with respect to tourniquet tolerance and onset time of surgical anaesthesia Motor bock set in earlier and recovered faster with lidocaine than ropivacaine after release of the distal tourniquet ($p < 0.05$, table). Recovery of sensation to pinprick took longer with ropivacaine than with lidocaine ($p < 0.05$) CNS side effects were more prominent after lidocaine than after ropivacaine ($p < 0\ 05$).

Discussion: Ropivacaine 0 2% has similar features as lidocaine 0.5% with respect to surgical anaesthesia and tourniquet tolerance. As a long acting local anaesthetic it generated a better analgesia and longer motor blockade after tourniquet release than lidocaine. Most importantly, side effects were substantially less pronounced than with lidocaine, making ropivacaine a potential alternative for use in IVRA.

Recovery of sensory and motor function (% of baseline)

	Sens3	Sens10	Sens30	Mot3	Mot 10	Mot 30
Lido	71 ± 31	89 ± 15	94 ± 12	65 ± 21	79 ± 18	87 ± 16
Ropi	52 ± 35	65 ± 31	78 ± 28	45 ± 13	60 ± 23	65 ± 25

A.378 Total knee replacement: a comparison of ropivacaine and bupivacaine in combined femoral and sciatic block

D. McNamee, P. Convery, K. Milligan. *Department of Anaesthetics, Musgrave Park Hospital, Belfast, N Ireland*

Background & Goal of Study: This study was designed to compare post-operative analgesia provided by femoral and sciatic nerve block following total knee replacement using either bupivacaine or ropivacaine. A control group received no blockade.

Materials & Methods: Following Ethical Committee approval, informed consent was obtained from 60 ASA 1–3 patients scheduled for elective unilateral primary total knee replacement. Oral diazepam 10 mg was administered 1 hr pre-op. Spinal anaesthesia was administered with 2.0–3.0 ml 0.5% heavy bupivacaine + 0.75 mg diamorphine with the operative side down. Patients were then randomised into one of three groups. Group A received no further intervention. Group B received 2 mg/kg 0 75% bupivacaine divided equally between the femoral and sciatic nerves. Group C received 2 mg/kg 0 75% ropivacaine divided equally between the femoral and sciatic nerves. All nerve blocks were carried out by an anaesthetist blinded to the grouping using a Braun Stimuplex with a 22G insulated needle. Time to first morphine, morphine consumption and VAS pain scores were assessed at 4 hrly intervals by nursing staff blinded to group allocation.

Results: Time to first morphine consumption was significantly longer in groups B and C than group A. Morphine consumption was significantly reduced at all times in group B compared with group A Morphine consumption was significantly reduced for the first 28 hours in group C compared with group A There were no significant differences in morphine consumption between groups B & C. There was no significant difference in pain scores between the two groups. (ANOVA analysis, $p < 0\ 05$ as significant).

Conclusions: Additional femoral and sciatic nerve blockade with either bupivacaine or ropivacaine following spinal anaesthesia provided prolonged analgesia when compared spinal anaesthesia alone. Bupivacaine provided a greater reduction in morphine consumption than ropivacaine.

A.379 Anterior approach to sciatic nerve block: a new landmark

I Pagani, I. Pellicioli, E. Viola[1], P Colazzo *II Dept. of Anaesthesiology;* [1] *Orthopaedic Clinic, University of Pavia, IRCCS Policlinico S Matteo 27100 Pavia, Italy*

The anterior approach to the sciatic nerve block offers several advantages. 1) it requires no change in the patient's position to perform other blocks of the lower limb, 2) it causes no discomfort or hazard to the traumatized patient However, this technique is considered difficult and at risk of damaging major blood vessels (1). Here we describe a new anterior approach to the sciatic nerve With the patient laying supine and the lower extremity in neutral position, the great trochanter was identified and marked (G) From this point, a straight line (GX) of 10 cm, parallel to the femoral shaft, was drawn, and the end point marked (X). Afterwards, the medial edge of the patient's rectus femur muscle was identified by muscular contraction and lined. The intersection between this line and the line perpendicular to GX segment, meeting point X, was the point of injection. The sciatic nerve was identified by a peripheral nerve stimulator-aided technique. A 20–21 G short bevel, 15 cm long, insulated needle was used in all cases. When the tip of the needle met the anterior medial surface of the femur, the needle was withdrawn to the subcutaneous tissue and redirected perpendicularly until a muscular activity was evoked in the tibial and peroneal nerve supply (usually at a depth of 9–12 cm). Then, 30 ml of mepivacaine 1% plus adrenaline 1/400.000, alkalinized 1/10 with sodium bicarbonate 8 4% were injected First we performed the block of the femoral, lateral femoral cutaneous and obturator nerves with 30 ml of the same anesthetic solution, then the block of the sciatic nerve, in order to minimize the patient's discomfort (the thigh is already anaesthetized). The block was used, after informed consent, on 114 patients (70 males, 44 females) undergoing orthopaedic surgery of the lower limb (arthroscopy = 90, tibial osteotomy and osteosynthesis = 11, tendon repair = 8, others = 5). The block was complete (no discomfort during surgery) in 89 5% of the patients, and fair (supplementation with sedatives and/or narcotics or peripheral local anaesthesia) in 7%. In 4 cases (3.5%) the block failed, and a posterior approach was necessary. Therefore sciatic nerve was identified on the first attempt in 18 cases, on the second in 43, on the third in 32, on the fourth in 17 cases The mean dose of mepivacaine injected was 8 10 mg^*kg^{-1} (range 5.3–12) The time of onset was 7 1 ± 3.4 min (range 4–20), the latency of complete block was 11 9 ± 4.5 min (range 6–25). The duration of anaesthesia was 272 ± 73 min, while that of analgesia was 290 ± 72 min. The degree of anaesthesia was always adequate for applying a tourniquet without pain. Our modified technique had high acceptance by the patients (91.2% very satisfied, 8 8% enough satisfied), especially in subjects with lower extremity fractures. During the study, neither clinically relevant side effects nor sequelae were observed. In conclusion, our technique of anterior sciatic nerve block proved to be reliable, easy and safe for lower limb surgery (except for femur).

A.380 Continuous popliteal sciatic nerve block catheter: incidence of complications

P. Cuvillon, P. Bruelle, E Touabtia, V. Piffaut, J.J. Eledjam. *DAR, CHU Nîmes, 5 rue Hoche, 30 029 Nîmes cedex, France*

Background and Goal of Study: CPSNBC is an efficient and reliable postoperative analgesia technique after major elective foot orthopedic surgery (FOS). The aims of the study were to identify the incidence of complications with this technique.

Materials and Methods: After informed consent, patients (P) were prospectively studied Before spinal anesthesia and surgery, catheter (C) (Contiplex°, France) was inserted (ventral position) (VP) in the popliteal fossa (1) using a neurostimulation technique (2) An initial bolus was injected, followed by a constant infusion of bupivacaine 0 125%, 10 ml/h We noted: time (T) to inserted C (T between the operator begin to wash his hands to the end of the procedure), immediates complications, complications over 48 h, and 3 weeks later

Results and Discussion: 21 P (8 males, 13 females, 69 ± 13 kg, 169 ± 10 cm; 45 ± 20 years).

(1) Technique of insertion· No P refused to stay in VP Mean T· 16 mn (SD: ± 7.5 mn) Mean stimulation· 0 3 mA (always <0 5 mA).

(2) Immediate complication No vascular ponction, no failure (included reaseach of sciatic nerve), no difficulty to injected, no paresthesia were observed. No difficulty to inserted the C in the popliteal fossa up to 5 to 10 cm in the perinervous space.

(3) Complications after 48 hours· 1 motor block (stopped at the end of perfusion), 3 C culture + without any incidence, mean morphine consumption: day one: 2.4 mg (SD· ± 3 5); 0 mg for 15 patient (EVA < 30) Day 2· 2.6 mg (SD. ± 6 1); 0 mg for 13 P. No accidental withdrawal C.

(4) No nervous complication after 3 and 6 weeks

For next surgery, all patients will accepted CPSNBC

Conclusion: The efficient and very low rate of complications with CPSNBC might be an interesting challenge for major FOS surgery.

A.381 Continuous analgesia with a femoral catheter: plexus or trunk blockade?

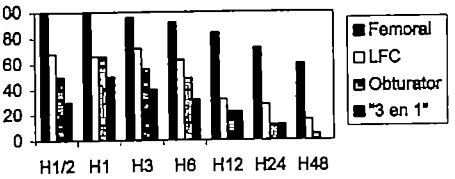
Y. Barthelet, X. Capdevila, E. André, N. Vialles, P Biboulet, F d'Athis
Department of Anesthesiology and Intensive Care "A" Montpellier, France

Background & Goal of Study: Commonly, physicians using a femoral catheter for postoperative analgesia after hip or knee surgery consider that they produce a continuous lumbar plexus blockade [1, 2]. Nevertheless, none of them perform a neurologic testing to prove it The aim of this study was to evaluate the extent of sensory blockade produced by a continuous infusion in a femoral catheter throughout a 48 H period

Materials & Methods: After informed consent, 20 patients scheduled for major knee surgery were prospectively included Following a standardized general anesthesia, a femoral catheter was introduced and advanced 12–15 cm cephalad in the femoral nerve sheath, using a nerve stimulator. In the recovery room, a 30 mL bolus of 2% lidocaine with 1/200 000 epinephrine was given, followed by a 48 hours continuous infusion of 1% lidocaine + 0.03 mg/ml morphine + 2 μ/ml clonidine (rate. 0 1 ml/kg/hour)

The sensory blockade was assessed at H$\frac{1}{2}$, H1, H3, H6, H12, H24 and 48 H using the pinprick method in the femoral, lateral femoral cutaneous (LFC) and obturator nerves territories The quality of analgesia was assessed by using a visual analogic scale ranging from 0 (no pain) to 100 mm (worst possible pain) at the same times

Results & Discussion: The block produced by the 30 mL induction bolus was not constantly a "3-in-1" blockade (50% of cases in our study). While maintaining analgesia by a continuous infusion, sensory blockade affects the three main nerves of the lumbar plexus in less than 20% of patients after 6 hours Sensory blockade was limited to the femoral nerve in 44 to 52% of patients after 12 hours [figure 1] However, this sensory blockade provide effective pain relief and the median VAS values were lesser than 40 mm at any times in the study



Conclusion: Our findings contradict the commonly "continuous lumbar plexus block" appellation used in previous studies An isolated femoral nerve sensory blockade appears after several hours, sometimes associated with lateral femoral cutaneous and/or obturator nerves blockade. "Continuous femoral block" should be more appropriate to describe the prolonged use of a femoral catheter for postoperative analgesia

A.382 Analgesia for total hip arthroplasty with posterior lumbar plexus block

R. Stevens, E. Van Gessel, N. Flory, Z. Gamulin. *Division of Anaesthesiology, University Hospital, 1211 Geneva 14, Switzerland*

Background: Sensory afferents from the hip involve mainly the lumbar plexus (LP). Uncontrolled studies have shown that pain related to hip surgery can be effectively managed with LP blockade (1) However, the anterior "3-in-1" approach does not predictably block all major trunks of the LP, and the usefulness of this technique was questioned in a recent study (2) In this randomised controlled double blind trial, we evaluate the analgesic effect of LP blockade using a posterior approach.

Methods: After institutional approval and informed consent, 41 patients ASA I-III undergoing total hip arthroplasty were allocated general anaesthesia with (n = 21) or without (n = 20) posterior LP block. Block was performed after induction using a nerve stimulator (≤0.4 mA) and following Winnie's description (3), and 0.4 ml/kg bupivacaine 0 5% with epinephrine was injected. Intraoperatively, increments of fentanyl were administered as needed by a physician blinded to treatment allocation Postoperative pain (VAS) and PCA morphine consumption were assessed for 48 hours. Inadequate analgesia was supplemented in the PACU by boluses of i.v "rescue" morphine Means are given ± SD and groups compared using the unpaired Student's *t*-test or the chi-squared test as required

Results: Baseline variables in both groups were similar. Intraoperatively, the number of patients requiring additional fentanyl was >3 times higher in the group without the block (17/20 vs 5/21, $p = 0.02$). Upon arrival in the PACU, a fivefold reduction in mean pain scores was observed in patients receiving the block (VAS 1.1 ± 2.1 vs 5.7 ± 2 9, $p < 0.00001$) Rescue morphine was needed by 14/20 in the untreated group, against 1/21 in the group with the block ($p < 0.0001$). In the latter group, cumulative morphine consumption remained lower until 12 hours after administration of the block (13.1 ± 9.7 vs 19.7 ± 10.8 mg, $p = 0.04$) Epidural-like distribution was noted in 3/21 patients (14%) without adverse consequences.

Conclusions: LP blockade using the posterior approach offers effective pain relief after hip surgery. Our results also suggest a block-related intraoperative opioid-sparing effect The technique is safe but incidence of epidural-type spread is not negligible.

A.383 Regional anaesthesia for femoral neck fracture surgery: comparison of lumbar plexus block and spinal anaesthesia

L. Eyrolle[1], P. Zetlaoui[2], A Belbachir[1], N. Rosencher[1], Ch. Conseiller[1].
[1] *CochinPort-Royal University Hospital Paris;* [2] *Bicêtre University Hospital Kremlin-Bicêtre, France*

Background & Goal: Regional Anesthesia does not significantly improve outcome of patients after femoral neck fracture surgery (1). A posterior LBP affords more theoretical benefits on commonly practiced Spinal Anesthesia. The aim of this study is to evaluate efficacy and safety of LBP in comparison with SA in patients undergoing femoral neck osteosynthesis.

Patients & Methods: Both techniques were prospectively evaluated in 50 patients randomized in two groups after Ethical Committee approval: 1) SA with single shot Bupivacaine 0 5%. 2) Posterior LPB as described by Winnie (2), with nerve stimulator, and mixture of equal volumes lidocaine 2% + bupivacaine 0.5% with 1:200,000 epinephrine A light sedation by propofol IV was associated in case of discomfort during surgery Results are presented as mean ± SD Statistical analysis used non-parametric tests.

Results: The two groups were similar with regard to age (82 ± 12 y), weight, ASA status, and duration of surgery No significant complications were observed.

	LPB n = 25	SA n = 25	p
Insertion difficulties	3	10	<0 05
Propofol > 1 mg/kg/h	19	5	<0 01
Mean Art BP > 20%	3	18	<0 01
Ephédrine (mg)	1 2 ± 2 7	7 0 ± 2 6	<0 001
VAS H + 3 (mm)	14 ± 16	20 ± 24	NS
VAS H + 8 (mm)	26 ± 18	38 ± 24	NS
Adverse effects	1*	6**	<0 01

*1 AL Tox **1 PPDH 5 urin ret

Discussion: This study confirms the easiness and safety of LBP as compared with SA. Though by itself insufficient to provide good anesthesia for hip fractures surgery, LBP appears to be more suitable than SA with regard to hemodynamic changes and adverse effects. Surgery could be performed under light sedation with propofol in spontaneously breathing patients Lack of difference in postoperative analgesia may be related to the small size of the population. It is concluded that LBP must be reevaluated in association with sciatic or high paravertebral block for surgery of femoral neck fractures.

A.384 Clinical comparison between ropivacaine and bupivacaine for lower limb peripheral nerve block

P Beccaria[1], G. Fanelli[1], A Casati[1], G. Aldegheri[1], A. Leoni[1], E. Moizo[1], B. Borghi[2]. *Dept of Anaesthesiology;* [1] *IRCCS H. San Raffaele and* [2] *IRCCS H. Rizzoli, Bologna, Italy*

Background: The purpose of this prospective, randomized, double-blind study was to compare ropivacaine and bupivacaine during combined sciatico-femoral nerve block.

Methods: With Ethical Committee approval and patients' consent, 30 patients, ASA Physical status 1–2, scheduled for elective hallux valgus repair with thigh tourniquet were randomized to receive combined sciatico-femoral block by 0.75% ropivacaine (ROPI, n = 15) or 0 5% bupivacaine (BUPI, n = 15). For the femoral block 10 ml of anaesthetic solution were employed, while for the sciatic block 15 ml of the same solution were used. In order to obtain a correct localization of the block needle a nerve stimulator (Plexival, Medival, Italy) with insulated needles (Locoplex, Vygon, France) were used. A stimulation frequency of 2 Hz and a current ranging between 0.5 and 1 mA were used. Time required for onset of sensory and motor block and for resolution of motor block at operated foot, as well as onset of postsurgical pain and analgesics requirement were recorded. Mann-Whitney test and Fisher exact test were used as indicated A value of $P < 0.05$ was considered as significant

Results: The two groups were similar with respect to anthropometric parameters, duration of surgery and measured VAS pain scores. Main results are presented in the table

	ROPI (n = 15)	BUPI (n = 15)
Onset sens block (min)	14 ± 17	37 ± 27$
Onset mot block (min)	16 ± 10	51 ± 32$
Duration Analgesia (min)	670 ± 227	880 ± 312
Postop. Analgesics	7 (46%)	6 (40%)

$P < 0 001 vs RCPI

conclusion: This study demonstrated that 0 75% ropivacaine allows a latency of sciatico-femoral nerve block shorter than 0.5% bupivacaine with a prolonged postoperative pain relief

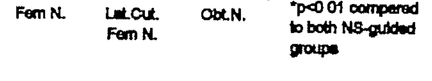
A.385 Ultrasonographic guidance reduces the amount of local anaesthetic for 3-in-1 blocks

P. Marhofer, C. Schrogendorfer, T. Wallner, S. Kapral, N. Mayer. *Dept of Anesthesiology an Gen. Intensive Care, University of Vienna, A-1090 Vienna, Austria*

Background: Recently it has been demonstrated that the use of ultrasound (US) improves the sensory blockade and the onset time of 3-in-1 blocks as compared to conventional nerve stimulator (NS) guided techniques (1). This study was designed to evaluate if US guidance reduces the amount of local anesthetic.

Methods: After institutional approval and informed consent 45 patients undergoing hip surgery following trauma were randomly assigned and double blinded to three groups. In the US group the 3-in-1 block was performed under US guidance with 20 mL bupivacaine 0.5%. In the NS guided groups the 3-in-1 block was performed under the guidance of a NS with 20 mL and 30 mL bupivacaine 0.5%. The quality and onset time of the sensory block was assessed by pinprick test in the central sensory region of each of the three nerves and compared to the same stimulation on the contralateral leg every 10 min for 60 min. The rating was undertaken using a scale from 100% (uncompromised sensibility) to 0% (no sensory sensation). All results were expressed an mean ± SED. Statistical analysis was performed by ANOVA and Student's t-test A $p < 0$ 01 was considered significant.

Results: US guidance reduces significantly the amount of local anesthetic to achieve satisfactory levels of anesthesia. Onset time for 3-in-1



*p<0 01 compared to both NS-guided groups block in the US group was significant shorter as in both NS groups (US 13 ± 7 min, NS 20 mL 27 ± 14 min, $p < 0.01$ and NS 30 mL 26 ± 16 min; $p < 0.01$ to group US) The quality of sensory block was also significant better in the US group as compared to both NS groups (Figure).

Conclusions: The new US guided technique for 3-in-1 blocks has a better onset time and quality of sensory blockade as compared to the NS guided 3-in-1 when the same amount of local anesthetic were administered The increase of local anesthetic of 50% has no benefit for NS guided 3-in-1 blocks Therefore, US guidance reduces the amount of local anesthetic

A.386 Comparison of the "3 in 1" and "fascia iliaca compartment" blocks in adults: clinical and radiographical analysis

Xavier Capdevila, Philippe Biboulet, Yves Barthelet, Yves Ryckwaert, Françoise d'Athis *Department of Anesthesiology, Lapeyronie University Hospital, 34295 Montpellier, France*

Background and Goal of Study: In children, the fascia iliaca compartment block was reported to provide respectively 100%, 92% and 88% of sensory blockade of the femoral (F), obturator (O) and lateral femoral cutaneous (LFC) nerves In adults the '3 in 1' block was shown to be inconsistent in producing blockade of both the LFC and O nerves. The present study was designed to compare these two approaches in adults

Patients and Methods: After institutional approval, 100 patients scheduled to undergo either hip, femoral shaft or knee surgery were randomly assigned, for the postoperative pain relief, to '3 in 1' (group 1) or fascia iliaca compartment (group 2) blocks After general anesthesia, once the patients were awakened and extubated, the '3 in 1' block was realised using an insulated needle and a nerve stimulator and the fascia iliaca compartment block following Dalens et al (1) technique. The local anesthetic solution used for all patients was 30 ml of an equal volume mixture of 2% lidocaine with epinephrine and 0.5% bupivacaine to witch 5 ml of contrast media was added Sensory blockade was evaluated in the three nerve territories using cold and pinprick tests at ten min intervals over the 30 min period following injection. At 30 min, motor blockade of the F and O nerves was assessed and a frontal pelvic region's radiograph was taken

Results: Two block failures were noted in group 2. Complete lumbar plexus block was achieved in 38% group 1 and 34% group 2 patients. Sensory blockade of the F nerve was obtained in 90% and 88%; of the O nerve in 52% and 38% and of the LFC nerve in 62% and 90% ($p < 0.05$) respectively in groups 1 and 2 Sensory LFC nerve blockade was obtained more rapidly in group 2 ($p < 0.05$) A motor blockade of F and O nerves was effective in 76% and 32% group 1 and 80% and 20% group 2 patients. The anesthetic solution reached the lumbar plexus in only 5 radiographs A concurrent internal and external spread, under the fascia iliaca, was noted in 62 of the 92 radiographs analysed. Isolated external spread, under the fascia iliaca and over the iliacus muscle, were noted in 10% and 36% of the patients in group 1 and 2 ($p < 0.05$) The O was never blocked in the external spreads.

Discussion and Conclusion: The fascia iliaca compartment block is more effective than the '3 in 1' block in producing simultaneous blockade of the LFC and F nerves in adults. Following both procedures, blockade was obtained primarily by the spread of local anesthetic under the fascia iliaca and only rarely by contact to the lumbar plexus.

A.388 Improved regional blockade prolongation method from mixture of local anaesthetics

Jeong Ok Lim, Woon Yi Baek[1] *Medical Research Institute, Dept. of Anesthesiology[1] School of Medicine, Kyungpook National University, Taegu, 700–721, Korea*

Background & Objectives: Previous efforts to prolong the duration of local anesthetics by means of lipid carrier, liposphere, pellets, microspheres have concentrated on employing single local anesthetic[1–3]. Each local anesthetic has its own property. Lidocaine is pharmacologically safe and fast in onset time but has short action duration, while bupivacaine is a highly potent local anesthetic having comparatively slow onset time and higher side effect than lidocaine In this paper mixture of lidocaine and bupivacaine is formulated into pellet with a biodegradable polymer for improving the prolongation of nerve block by taking advantages of each constituent local anesthetic The formulated pellet was evaluated for its efficacy and safety

Materials and Methods: Pellet was prepared by a modified melting molding process[2] with 30 wt % poly (dl-lactide-co-glycolide), 35 wt % lidocaine and 35 wt % bupivacaine. In vitro release kinetic study was carried out by incubation of the pellet in phosphate buffered saline Released drug was assayed by high performance liquid chromatography Rat sciatic nerve model[3] was used for in vivo evaluation of the pellet using an analgesiometer. Local anesthetic dosage used was 70 mg/kg for lidocaine and bupivacaine, respectively One month after implantation, histological examination of the nerve tissue adjacent to the pellet was performed Sensory block data were analyzed by paired t-test using SAS 6.03

Results and Discussion: In vitro release profile demonstrated that both anesthetics released in controlled manner and lidocaine released in fast rate while bupivacaine relatively in slow rate. Approximately 80% of the total local anesthetics was released within 3 ~ 4 days Five male Sprague-Dawley weighing 250–300 g produced prolonged sciatic nerve blockade for periods lasting 3 days Previous study[2] using single bupivacaine with dose of 150 mg/kg resulted in prolonging the duration to 3–5 days This finding demonstrated that the mixture system is a improved method by reducing the dosage to half and obtaining almost equivalent effect All of the animals appeared to recover in 4 days Histology examination showed no evidence of nerve tissue damage

Conclusion: The results indicated that the mixture system showed a promising approach to improve the prolongation of local anesthetics

A.389 Peroperative analgesic effects of clonidine and fentanyl administered by systemic and/or epidural routes

E. Barrera, E. Samsó, J. Vallés, M.M. Puig *Department of Anaesthesiology, Hospital Universitario del Mar, Barcelona, Spain*

Background & Goal: Opioids and α_2 agonists provide effective analgesia in different animal models and in humans Animal studies show that when administered simultaneously by the spinal route, a synergistic interaction occurs; however this interaction has not been demonstrated in humans The aim of the study was to evaluate a possible interaction between fentanyl (FN) and clonidine (CL), administered by the intramuscular (i.m.) and the epidural (e.p.) routes, in patients undergoing total hip replacement (THR).

Material & Methods: After institutional approval and informed consent, fifty ASA I–II patients scheduled for THR where randomly distributed into five groups that received 150 μg of FN and CL or saline (SS) by the following routes:

Group	I	II	III	IV	V
e p	SS	FN	CL	FN + CL	SS
i m	FN + CL	CL	FN	SS	SS

Study drugs were administered double blind before induction. Surgical anaesthesia was maintained with 60% N_2O in O_2, and Isoflurane (ISO) given at the required concentrations to maintain MAP and HR within 20% of baseline. We assessed: intraoperative ISO requirements (%, AUC), pain intensity (VAS) and sedation (Ramsay, SED) evaluated on arrival to recovery (VAS-RR) and at the time of analgesia request (VAS-TAR). Results were analyzed by ANOVA

Results & Discussion: All groups were comparable regarding demographic data, baseline MAP/HR, duration of surgery and degree of sedation Results are expressed as mean values (SD not shown)

GR	% ISO	ISO (AUC)	VAS-RR	TAR (min)	VAS-TAR
I	0.28	36	7.3	7	8.5
II	0.24	39	4.8	30	6.8
III	0.20	40	3.8	33	7.3
IV	0.14	24	1.3*	68*	7.3
V	0.92*	137*	4.8	23	8.1

ISO requirements were reduced in all groups (*$P < 0.05$) in relation to saline. Lowest ISO concentrations were required when FN and CL were given epidurally (Group IV), in the same group, VAS-RR was significantly lower (*$P < 0.05$) and the TAR prolonged (*$P < 0.05$) when compared to the rest of the groups

Conclusions: The simultaneous administration of 150 μg epidural FE and CL induces a reduction in ISO requirements and post-operative analgesia. The effects of the drugs seem to be additive (no interaction)

Partially Supported by FIS 94/1380.

A.390 Effects of clonidine on conductances active during post-tetanic hyperpolarization in peripheral nerve: studies of local anaesthetic action of clonidine

C Dalle, C. Bretton, M Schneider[1], F Clergue, P Jirounek *Dept. APSIC, CMU, 1211 Genève4, Suisse and [1]Dept. Anesthésie, Hôpital Univ, 4301 Bâle, Suisse, France*

Background: Coadministration of local anesthetics and Clonidine (Clo), an α2 adrenoceptor agonist, enhances the duration and intensity of peripheral nerve block (1). Clinical observations and in vitro studies suggest that the local anesthetic effect of Clo may be due to direct action on the C fibers (small, unmyelinated fibers responsible for pain transmission) In recent experiments, we showed that Clo increases and prolongs post-tetanic hyperpolarization (PTH), following a train of action potentials in peripheral nerve. This effect is reversible and dose-dependent at tested concentrations (EC50 = 20 μM) and could be mediated through α2-adrenoceptors (2). Such a prolongation of hyperpolarization limits the frequency of discharge by increasing the firing threshold and thus might contribute to the modulation of sensory input The present study was undertaken to determine the mechanisms by which Clo enhances PTH and thus affects peripheral impulse conduction

Methods: The effects of Clo on post-tetanic membrane potential were examined in the desheathed rabbit vagus nerve by the sucrose-gap method. The C-fiber monophasic compound action potentials were elicited by supramaximal stimulation and PTH was recorded after a train of action potentials (10 s, 15 Hz). Test solutions were applied for 20 min All experiments were carried out at room temperature

Results: Pharmacological studies show that Clo increases and prolongs PTH in a similar manner to potassium conductances blockers (Barium, Césium, TEA). These conductances are hyperpolarization-activated inward currents which short-circuit the major part of the hyperpolarization due to the hyperactivity of the Na+/K+ pump following tetanic stimulation (3)

Discussion and Conclusion: On the basis of these results, the hypothesis is that Clo may inhibit inwardly rectifying potassium channels. To characterize and study the effects of Clo on potassium conductances, the patch-clamp technique will be used on rat nodose ganglion and dorsal root ganglion neuron cell bodies. A better understanding of mechanisms by wich Clo interrupts impulse conduction in peripheral nerve may facilitate search for more specific pharmacological substances and may determine optimum drug combinations reproducing powerful analgesia with less side effects

A.391 Effects and plasma concentrations of clonidine added to local anaesthetics for axillary plexus blocks

J.-M. Bernard, R Delpech, D. Le Roux, P. Mouton *Department of Anaesthesia, Polyclinique Jean-Villar, 33520 Bruges, France*

Background and Goal of the Study: Clonidine (C) has been shown to enhance peripheral neural blockade when added to local anaesthetics, owing to a local action (1). However, a central analgesic effect due to blood absorption cannot be definitely excluded in the absence of pharmacokinetic study. This double-blind randomised study compared clinical effects and plasma concentrations of C added to local anaesthetics for axillary nerve block and those of C intramuscularly injected

Materials and Methods: After informed consent and institutional approval, 20 ASA-1 patients, scheduled for carpal tunnel repair, were studied. All axillary nerve blocks were performed by injection of lidocaine (200 mg) and bupivacaine (150 mg) after identifying the median nerve by a stimulator. C (150 mg) was given at random either with local anaesthetics (Group With; n = 10) or intramuscularly (Group IM; n = 10) To ensure that the study was double-blind, saline was injected intramuscularly in Group With. Sensory blocks using pinprick test in both ipsi- and controlateral upper limbs, blood pressure, heart rate, and sedation (from 0 = alert to 4 = comatose) were measured before and 20, 40, 60 and 120 min after injections. At these times, plasma C concentrations were measured by radioimmunoassay method (Bioscienta). Data were analysed by contingency table and ANOVA *P* was set at 0 05

Results and Discussion: Patients were sedated similarly in both groups. Haemodynamics were unchanged. C concentrations as well as sensory block intensity expressed as the ratio of ipsi- and controlateral pinprick scores were greater in Group With (Table).

Conclusion: Increased blood absorption of C may partly account for enhancement of the sensory block when C is added to local anaesthetics

A.392 Addition of nalbuphine to peribulbar anaesthesia: clinical usefulness?

A. Saaifan, C Cornet, J. Borgo, N Belut, M. Labrude[1], J.P. Berrod[2], G. Audibert, M.C Laxenaire. *Dépt d'anesthésie-réanimation; [1]Pharmacie centrale; [2]Service d'Ophtalmologie, Hôpital Central Nancy, France*

Background: The aim of this study was to compare analgesic effects, side effects and requirements for supplemental analgesic therapy after retinal detachment surgery performed under peribulbar anaesthesia, in patients given peribulbar (PB) or subcutaneous (SC) nalbuphine.

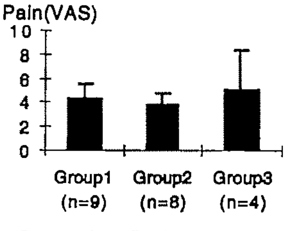
Methods: After institutional approval, in a randomized, double blind controlled trial, 98 patients each received two solutions with PB anaesthesia (2% lidocaine-0 5% bupivacaine) one PB and the other SC. Group 1 (n = 34) received 1 ml PB plus 1 ml SC of normal saline. Group 2 (n = 30) received 1 ml nalbuphine (10 mg) PB plus 1 ml SC of normal saline Group 3 (n = 34) received 1 ml PB of normal saline plus 1 ml SC of nalbuphine Pain was evaluated at the end of the surgery and 1, 2, 3, 4, 8, 12 and 24 h afterwards, using a linear visual analogue scale (VAS) from 0 (no pain) to 10 (the worst imaginable pain). Patients whose pain exceeded 3/10 received iv propacetamol 2 g every 6 h. IV ketoprofen was added every 8 hours if pain still exceeded 3/10. Side effects were recorded at each pain evaluation.

Results: The 3 groups were comparable in age, sex ratio, weight, surgical duration and type of procedure (scleral buckling and transscleral cryo) VAS pain rating were low in all groups. Only 22% patients had pain scores at 3/10 or above (figure) Duration of adequate analgesia did not differ between groups (table). All groups were comparable in analgesic requirements.

Duration of adequate analgesia (minutes)

	Group 1	Group 2	Group 3
Mean	189 ± 106	164 ± 93	251 ± 197
Range	50–337	63–276	85–537

mean ± SD, NS



Conclusion: Peribulbar anaesthesia provided adequate postoperative pain relief after retinal detachment surgery. The results of this study suggest that addition of nalbuphine to local anaesthesia does not improve postoperative analgesia.

A.393 Does systemic verapamil potentiate spinal anaesthesia?

E. Tomatır, S. Serin, H Atalay, H. Erbay, L Kaplan, M Gönullü
Pamukkale University, Medical Faculty, Dept. of Anaesth. and Int. Care, Denizli, Turkey

Background & Goal of Study: It has been experimentally shown that intrathecal administration of calcium channel blocker and local anaesthetic combination produces more potent sensory and motor blockade (1) However, the effects of systemically administered calcium channel blockers on spinal anaesthesia are unknown. We aimed to assess whether systemic administration of verapamil potentiates spinal anaesthesia

Materials & Methods: In order to avoid possible deep hypotension, only patients who would have been planned saddle blockade were selected. 20 ASA class I or II adult patients, were randomly divided into two equal groups Verapamil of 5 mg or saline (C) of 1 ml as control was given intravenously 30 minutes before the blockade, and then spinal saddle blockade was performed using 2 ml bupivacaine of 0.5%. Sensory blockade was assessed with Pin-prick test, and voluntary control of anal sphincter was used to assess motor blockade. The times (T) from the intrathecal administration of bupivacaine to the beginning (B), completion (C) and resolution (R) of sensory (S) and motor (M) blockade were measured. Arterial blood pressures and heart rates were monitored. Student's t and Chi-square tests were used for statistical analysis Data are expressed as mean ± standard error $P < 0\ 05$ was considered significant

Results & Discussion: Both groups were comparable for demographic data. There were no statistically significant differences between the two groups for the times about blockade shown in table. Arterial blood pressure was lower in verapamil group when compared with control group at 30th min ($P < 0.05$)

	T-BS (sec)	T-BM (sec)	T-CS (sec)	T-CM (sec)	T-RS (min)	T-RM (min)
V	78 ± 19	126 ± 32	169 ± 70	204 ± 53	216 ± 25	229 ± 52
C	46 ± 12	61 ± 14	113 ± 55	158 ± 81	180 ± 18	263 ± 35

No potentialization of spinal anaesthesia in our study may be explained with the assumption the dose of verapamil can not produce enough concentrations required for interaction with local anaesthetic in spinal cord

Conclusion: We concluded that the systemic administration of 5 mg verapamil does not potentiate spinal anaesthesia.

A.394 A comparison between subarachnoid administration of bupivacaine 0.5%, mepivacaine 2% and prilocaine 5% based on a pharmacodynamic model

A Faura, P. Gambús, I.F Trocóniz[1], E Izquierdo, L Parra, D. Pelegrí.
Anesthesia Dpt., Hospital de Viladecans Barcelona, [1]Pharmacy Dpt, Univ. de Navarra, Pamplona, Spain

Background and Goal of the Study: A mathematical model for the analgesic effect of subarachnoidally administered 0 5% Bupivacaine (BPV), has been recently described[1]. Using the same structural model, we wanted to estimate the parameters for 2% Mepivacaine (MPV) and 5% Prilocaine (PRL), and compare it to BPV

Materials and Methods: 37 adult consenting patients were enrolled in the study and assigned to receive either MPV (28) or PRL (9) The anesthetic was injected via a Withacre 25G spinal needle at L3–L4 level in the sitting position Doses ranged from 70 to 92 mg (MPV) and 65 to 90 mg (PRL) The level of blockade was measured periodically (pinprick) until analgesia dissipated enough as to enable complete movement of both legs Nonlinear mixed effects modeling (NONMEM) was used to estimate the parameters of the model and the variability (inter and intra individual) for MPV and PRL Based on this predictions, onset time (time to reach T10), duration (time above T10) and offset time (time from Emax to L1) were calculated and compared to BPV[1].

Results: The graph shows the time course of effect for BPV (12 mg dose), MPV (80 mg), PRL (80 mg), according to the model predictions. Relevant end points based on typical values are reported on the table

	BPV	MPV	PRL
Onset (min)	1	4	7
Duration (min)	272	112	58
Offset (min)	294	114	78

Conclusion: Based on model predictions, PRL had a significantly shorter duration and a faster offset. Estimates of interindividual variability around the parameters of the model were important in the case of PRL, probably due to the small number of individuals Further studies should be needed to corroborate these results.

A.395 A pharmacodynamic model for the effect of subarachnoid injection of bupivacaine 0.5%: prospective validation

P. Gambús, I F Trocóniz[1], A Faura, M J Linares, A Abad, D Pelegrí
Anesthesia Dpt., Hospital de Viladecans Barcelona, [1]Pharmacy Dpt, Univ de Navarra, Pamplona, Spain

Background and Goal of the Study: The use of mathematical models to describe the relations between drug administration and effect, enables us to elaborate predictions of expected effect, in slightly different clinical scenarios. After a model is constructed, it is convenient to validate it prospectively in a different population Our goal was to validate the following model by Schnider et al[1]

$$L_p = E_m \times \frac{\text{Dose} \times (e^{-\alpha_1 t} - e^{-\alpha_2 t})}{F + \text{Dose} \times (e^{-\alpha_1 t} - e^{-\alpha_2 t})}$$

where L_p stands for the level predicted, E_m for the maximal level, α_1 and α_2 are the rate constants for onset and offset of effect and F is a scaling factor, to characterize the relation between subarachnoidally injected 0 5% plain Bupivacaine (BPV) and the effect considered as the level of blockade achieved.

Materials and Methods: 12 adult consenting patients were enrolled in the study. 0 5% BPV was injected subarachnoidally via a Withacre 25G spinal needle at L_3–L_4 level in the sitting position The dose ranged from 10 to 15 mg The level of blockade was measured periodically (pinprick) until analgesia dissipated enough as to enable complete movement of both legs. Nonlinear mixed effects modeling (with NONMEM) was used to estimate the robustness of the model in describing our observations

Results and Discussion: The parameters that we estimated based on our data are reported in the table and compared to the originally described by Schnider et al[1]

	α1 (min^{-1})	α2 (min^{-1})	F	Emax
Gambús	0 015 (18)	0 053 (23)	0 86 (43)	T4 (0 4)
Schnider	0 012 (8)	0 0608 (16)	0 22 (23)	T4 (2 1)

reported as values (%CV) An empirical bayesian estimation with the model and parameters from Schnider et al[1], was able to predict our observations adequately

Conclusions: An estimated median absolute prediction error (MDAPE) of 5 2% demonstrates good accuracy of the model in describing our observations Differences were detected around the scaling factor F, perhaps due to the small number of individuals in our population (12) compared to the original description of the model (96). This model can be used to predict analgesic effect after spinal administration of 0 5% BPV

A.396 Unilateral spinal anaesthesia: effects of speed of intrathecal injection

A. Casati, G. Aldeghen, G L Cappelleri, A. Leoni, M Berti, G Fanelli
University of Milan, Dept. of Anaesthesiology IRCCS H San Raffaele, via Olgettina 60, 20132 Milan, Italy

Background: It is currently believed that rapid injection of the local anaesthetic solution during unilateral spinal anaesthesia causes turbulence that could modify its distribution into the spinal canal The aim of this randomized, double-blind study was to evaluate whether the speed of intrathecal injection affects lateral distribution of spinal block

Methods: With Ethic Committee approval and patient consent, spinal anaesthesia was performed by 8 mg of 0 5% hyperbaric bupivacaine in 30 patients scheduled for unilateral leg surgery Dural puncture was performed by 25-gauge Whitacre spinal needle (Becton-Dickinson, N J , USA). After free flow of cerebrospinal fluid was observed, the needle bevel was turned toward dependent side of spinal canal, then patients were randomized to receive anaesthetic solution injected over 80 sec (SLOW, n = 15) or 6 sec (FAST, n = 15) Lateral position was maintained for 15 min with the side to be operated upon dependent The presence of an adequate sensory (above L_1) and motor (3°) blocks on surgical side, without one or both modalities on non-surgical side, or sensory and motor blocks lasting 20% longer on operated than non-operated side was defined as successful unilateral spinal anaesthesia Mann-Whitney test and Fisher exact test were used as indicated A value of $P < 0.05$ was considered as significant

Results: The two groups were comparable concerning anthropometric data and haemodynamic changes. Main results are presented in the table

	Slow (n = 15)	Fast (n = 15)
Unilateral sensory block	13 (86%)	8 (53)
Unilateral motor block	13 (86%)	10 (66%)

No significant differences in lateral distribution of spinal block were observed between the two groups. No differences in the number of patients showing sensory and motor blocks 20% longer on operated than on non-operated side were observed between the two groups.

Conclusion: Our results demonstrated that speed of intrathecal injection does not affect preferential distribution of 8 mg of 0.5% hyperbaric bupivacaine towards the operated side when a Whitacre spinal needle is used.

A.397 Continuous spinal anaesthesia with catheter over the needle: preliminary report

M. Wolfs, C. Mardirosoff, L. Dumont. *Brugmann University Hospital, Brussels, Belgium*

Background and Aims: Continuous spinal anaesthesia (CSA) using small gauge catheters is still a matter of debate, cauda equina syndrome being the most feared complication This study was designed to evaluate a new 24G spinal catheter threaded over a 27G Quincke spinal needle (Spinocath® B. Braun Medical Division)

Methods: After IRB approval and written patient consent, 14 ASA 1 or 2 patients scheduled for elective surgery of lower limbs or low abdominal region were studied. Catheter insertions were all made in a sitting position using a median approach at L2–L3 level. After epidural placement of the introducer, the 27G Quincke spinal with the "over the needle" 24G spinal catheter was introduced until the dural click was felt and free flow of CSF in the catheter was obtained. The wired 27G spinal needle was then removed and the 24G spinal catheter was threaded 3 cm into the subarachnoid space. 7.5 mg isobaric 0.375% bupivacaine was injected as initial dose and 3.75 mg increments were used in order to achieve a Th 10 sensory block level with a maximum of 15 mg We studied ease of insertion (dural click sensation, flow of CSF through the spinal catheter) We recorded frequency of catheter induced paraesthesia and we measured the efficiency of the first initial dose as well as the need of additional ones in order to achieve a sensory block level at Th10. We recorded presence of PDPH and neurological exams were performed the day after surgery

Results: Mean age was 64 years, mean weight was 81 Kg and mean height was 170 cm. Dural click was felt in 12 patients. CSF flow was obtained in 12 patients at first attempt within 5 seconds and, in 1 patient, three attempts were needed to thread the catheter up. Subarachnoid placement of the catheter was impossible in 2 patients. We recorded 80% catheter induced paraesthesia. Initial dose was efficient in 7 patients and a median sensory block level of Th4 was obtained. 2 patients required 1 top up in order to achieve a sensory block level above Th 10; median sensory block levels before top up were at L1 and at Th3 after. 2 patients needed 2 top ups (maximum dose); median sensory block levels before first top up were at L3, at L2 before the second and at Th7 after the second top up. 1 patient, despite maximum dose, kept to a level of Th12 No PDPH were recorded and neurological exams remained normal

Conclusions: Initial dose, when efficient, gave too high sensory block levels. The need of top ups is probably related to malposition of the spinal catheters. The catheter used is not predictable enough in the way it has been utilised in our study.

A.398 Continuous spinal anaesthesia: is there a risk of infection?

M Santamaria, M. Mollmann, T. Röttger, U A der Landwehr *Abteilung fur Anästhesie und operative Intensivmedizin St Franziskus-Hospital, D-48145 Münster, Germany*

Background and Goal of Study: The major benefit of continuous spinal anaesthesia (CSA) compared to single-shot spinal anaesthesia is that it allows subsequent injection of local anaesthetics. Moreover, it enables postoperative pain therapy. Potential risks of this method are lesions of nerves and/or vessels as well as infection. This study will contribute to research on the risk of infection.

Materials and Methods: In 144 patients (51 m/93 f) undergoing lower limb surgery, and who successfully underwent CSA, cerebrospinal fluid (CSF) was sampled both immediately after positioning and before removing the catheter. Leukocytes, proteins and glucose concentration were determined Meningism and infection parameters such as leukocytes in blood, CRP, ESR, temperature, skin lesions at the insertion site, were compared preoperatively and by removal. The catheter was removed under rigorous aseptic conditions. The tip was cut and washed with saline. CSF, tip and saline were cultured to establish whether there was microbiological contamination.

Results and Discussion: In 126 (87.5%) patients, all parameters could be determined. Leukocytes, proteins and glucose concentration in CSF did not change significantly. In five cases (3.9%), bacteria were found in CSF. The catheter tip was contaminated in eight cases (9.4%), and saline in one (0.8%) Staphylococcus epidermidis was the most frequently cultured microorganism. There is a statistically significant positive correlation (= 0.25) with the indwelling catheter time. Signs of local inflammation (erythema) at the insertion site appeared in three out of 24 cases (12.5%) with CSA lasting longer than 90 h Therefore, the catheter had to be removed. However, no patient showed evidence of local or systemic infection with CSA for up to 195.5 h.

Conclusions: CSA is a safe method in respect of infection risk, if it is used for up to 200 h An absolutely meticulous technique of insertion and handling the catheter is mandatory, as well as a daily inspection of local inflammation at the site of insertion

A.399 Respiratory muscle strength after spinal anaesthesia

J. Filby, J.S. Collins, P. Claydon, G.H. Mills *Department of Surgical & Anaesthetic Sciences, Royal Hallamshire and Northern General Hospitals, Sheffield, UK*

Background & Goal of Study: Spinal anaesthesia can produce motor block of the thoracic nerve roots and may therefore reduce both inspiratory and expiratory muscle strength. Measurements of peak inspiratory and expiratory flow have implied that weakness of these muscle groups occurs, however this has not been quantified by respiratory muscle assessment We therefore aimed to determine the relative reductions in both inspiratory and expiratory muscle strength following spinal anaesthesia.

Materials & Methods: 13 consecutive patients undergoing lower limb or urological surgery consented to take part in the study. Maximal inspiratory and expiratory mouth pressures (MIP, MEP) were measured preoperatively and at intervals during and after surgery using a PK Morgan Pmax monitor These tests rely on patient effort. To gauge the consistency of effort we asked patients to perform maximum hand grip manoeuvres with the nondominant hand, using a Jamar hand-grip dynamometer. A reduction in grip strength coinciding with a block level below T1 would suggest a reduction in volitional patient effort and suggest that corresponding respiratory efforts were also submaximal, allowing their exclusion. Patients received 2.5–3.0 mls 0.5% heavy bupivacaine and all measurements were made supine To reduce the effect of learning all measurements were recorded a minimum of 8 times before surgery. Data is presented as a percentage of the average of the 3 best preoperative measurements

Results & Discussion:

Time mins	Mean MIP	SD	Mean MEP	SD	Mean Grip	SD	Mean block level	SD
Pre	100		100		100		nil	
10	96	14	71	31	95	8	T7	2
30	92	15	66	27	95	10	T5	2
60	87	15	69	28	93	12	T6	2
90	89	14	73	26	96	9	T7	3
120	94	14	77	25	98	11	T9	3
150	93	12	81	26	97	14	T11	3
180	97	9	87	27	100	10	T12	2

We found that inspiratory muscle strength was only mildly affected however expiratory muscle strength was reduced to a maximum of 66% of preoperative values and had not fully recovered 3 hours after the commencement of the block.

Conclusion: We conclude that inspiratory muscle strength is little affected following spinal anaesthesia, however expiratory muscle strength is reduced and this is likely to reduce the patients ability to cough

A.400 A comparative efficacy study of hyperbaric lidocaine 1.5% and mepivacaine 2% for spinal anaesthesia

J.R Markey, R. Montiague, D.O Bird, E.R Pedicini, A P Winnie.
Department of Anesthesiology & Pain Management, Cook County Hospital, Chicago, Illinois, USA

Background: Recently, the safety of lidocaine as a spinal anesthetic has been questioned(1). Some have advocated using lower concentrations of lidocaine for spinal anesthesia(2).

Mepivicaine has been used in the past as a spinal anesthetic, but its popularity waned because of its longer duration of action especially at higher concentration(3). This study compares hyperbaric 2% mepivicaine with 1.5% lidocaine with regard to the onset, duration and quality of the subsequent motor and sensory block.

Methods: After obtaining IRB approval and informed consent, 35 ASA class 1–2 adult male/female patients about to undergo lower extremity, lower abdominal or genitourinary surgery were placed into one of two groups based on the anesthetic solution received. group 1 patients received 75 mg of a 2% mepivicaine in dextrose 3 3% in water (3.75 ml) and group 2 received 1.5% lidocaine in dextrose 7 5% in water (5 ml). Before placing the spinal solution all patients were prehydrated with 500 ml lactated Ringers solution and had standard monitors placed. The spinal solution was injected at a rate of 5 ml/sec while the patients were in the sitting position Following injection of the spinal anesthetic, patients were placed in the supine position and all measurements were taken by an anesthesiologist that was blinded to the anesthetic agent used. The onset degree and duration of sensory block was assessed by the patients response to pinprick and a modified bromage scale was used to assess the onset, degree and duration of motor blockade Results are expressed as the mean + SEM.

Results:

	1 5% lidocaine n = 19	2% mepivicaine n = 16
Time to maximum sensory level (min)	10 ± 1	10 ± 1
* Highest Dermatomal level (Thoracic) plus range	4 (6–2)	5 (8–2)
* Complete sensory recovery (min)	172 ± 22	242 ± 39
Time to maximum motor block (min)	7 ± 4	7 ± 3
* Complete motor recovery (min)	126 ± 23	203 ± 44

* Denotes $p < 0\ 05$

No patients experienced transient radiuclar irradiation.

Conclusion: From the initial results, hyperbaric 2% mepivicaine appears as clinically efficacious as lidocaine 1.5% for spinal anesthesia With regard to recovery from sensory and motor blockade, mepivicaine 2% requires significantly more time for complete recovery than does lidocaine

A.401 Influence of spread of hyperbaric spinal anaesthesia on quality and duration of spinal block

N Kooger Infante, Z Gamulin, E. Van Gessel, A Forster *Division d'anesthésiologie, University Hospital of Geneva, Switzerland*

Background and Goal of Study: According to Greene (1) local anesthetics (LA) are eliminated from the subarachnoid space by vascular absorption and diffusion across arachnoid and dura membranes. Theoretically, with a larger surface of diffusion and absorption, elimination of LA should be faster. Thus, if significantly different anesthetic levels are obtained with same dose of LA, elimination of LA in patients with higher levels should be accelerated. This phenomenon might be clinically evidenced by faster regression and shorter duration of spinal anesthesia. The present study was designed to evaluate this hypothesis

Methods: After institutional approval and individual informed consent, 40 ASA I-II patients scheduled for lower limb surgery under spinal anesthesia, were studied 3 ml (15 mg) of hyperbaric bupivacaine 0 5% were injected intrathecally with the patient in sitting position. After LA injection, in order to obtain significantly different anesthetic levels, the patients were randomly placed either in a horizontal or in a 30° elevated torso position, and remained in these positions until the end of the study period Sensory level and motor block were evaluated by patient's perception of cold (ether) and the Bromage scale every 15 min. until regression to L4 and/or total motor recovery. Appearance of pain at operative site was noted Results are expressed as mean ± SD or median (ranges) and were analysed using Mann-Whitney or unpaired Student-t test as required

Results: The main data are summarized on the following table.

	Horizontal (n = 20)	30° elevated torso (n = 20)
Max sensory level	T 3 5 (T1–T9)	T10 (T6–L1)**
Regr of 2 segm (min)	110 ± 30	159 ± 49**
Regr. to L4 (min)	269 ± 53	336 ± 58**
Max. motor block	4	4 (2–4) NS
Total mot recovery (min)	173 ± 34	233 ± 56**
Pain at op site (min)	220 ± 68	270 ± 56*

*$p < 0\ 05$ **$p < 0\ 005$

Conclusion: These results support our hypothesis: with identical doses of LA, duration of anesthesia was significantly longer in patients presenting lower anesthetic levels (smaller surface of LA elimination) indicating slower absorption and diffusion of LA from subarachnoid space.

A.402 Combined spinal/epidural anaesthesia. A prospective clinical comparison between the needle-through-needle and the double-segment techniques

P. De Negri[1], A Casati[2], A D'Ambrosio[1], V. Taganello[3], G Fanelli[2], F Tarantino[2]. [1]*H. Sollievo della Sofferenza, S G Rotondo,* [2]*H S Raffaele, Milano;* [3]*C.T.O. Roma, Italy*

Background: We conducted a prospective, randomized, blind study in order to compare the double-segment and the needle-through-needle techniques for combined spinal/epidural anesthesia (CSE)

Methods: With ethical committee approval and patient's consent, 90 patients receiving CSE for elective orthopedic and urologic surgery were randomized to receive CSE using the needle-through-needle techniques (SST, n = 45) by means of the "adjustable Durasafe®" spinal needle (Becton Dickinson, N J., USA), or the double-segment technique (DST, n = 45) All patients received intrathecal injection of 15 mg of 0 5% plain bupivacaine Impossible location of intrathecal space was recorded An observer blinded to CSE technique measured the time required from skin disinfection to achieving a sensory block up to T_{10} (pinprick) and the need for epidural top-up before surgery. The day after surgery patients were checked for neurologic complications, while acceptance of anaesthetic procedure was evaluated on a 2 point scale 1) good, I can repeat it if necessary, 2) bad, I would prefer a different technique if necessary Unpaired t-test and chi-square test were used as indicated A value of $P < 0.05$ was considered as significant

Results: Anthropometric data were similar in the two groups No neurologic complications were observed in both groups The tip-to-tip distance between spinal and Tuohy needle measured in the SST group at the end of anaesthetic procedure was 7.0 (range 2 1–15.0) mm Main results are shown in the table

	SST	DST
Anest Procedure (min)	23 5 ± 11	29 8 ± 8 9$
Failed dural penetration	3 (6 6%)	1 (2 2%)
Epidural top-up	5 (11%)	4 (8 8%)
Acceptance Good/Bad	40/5	29/16$

$$P < 0\ 01$ vs SST

Conclusions: The present study demonstrated that the needle-through-needle CSE allows a similar rate of successful spinal block, but is faster and better accepted by patients when compared to the sequential puncture. Spinal needle employed in SST group was fixed to the hub of Tuohy needle and protruded up to 15 mm beyond the tip of Tuohy needle: this may explain the low failure of dural puncture as compared to previous studies (1, 2).

A.403 Epidural anaesthesia reduces haemodynamic response to carbon dioxide insufflation during laparoscopic cholecystectomy

S.C. Alexa, I Acalovschi *Department of Anaesthesia and Intensive Care, University of Medicine and Pharmacy Cluj-Napoca, Romania*

Background and Goal of the Study: Peritoneal insufflation of CO_2 during laparoscopic cholecystectomy induces major hemodynamic changes characterized by an increase in mean arterial pressure and a decrease of cardiac index (1)

We investigated the effects of thoracic epidural anaesthesia compared to general anaesthesia on haemodynamic alterations during laparoscopic cholecystectomy

Materials and Methods: Twenty ASA I-II patients scheduled for laparoscopic cholecystectomy were randomised to receive general anaesthesia with controlled ventilation followed by IM pethidine administration 50–100 mg for postoperative analgesia (G group) or thoracic epidural 2% lignocaine with Adrenaline 1/200000 and Fentanyl 1 μg/kg intraoperatively with spontaneous ventilation (block T4-L2) supplemented with Midazolam and Fentanyl iv followed by continuous epidural 1% lignocaine with Fentanyl 2 μg/ml 5 ml/h with PCA of 2 ml boluses at 15 min interval 24 h postoperatively (E group) We monitored for both groups mean arterial pressure (MAP), heart rate (HR), $ETCO_2$ and SaO_2 before the induction of anaesthesia (1), after induction of anaesthesia (2), 2 min after anti-Trendelenburg 30° (3), 5 (4), 10 (%), 15 (6) min after peritoneal insufflation and 2 min after CO2 exsufflation (7). Statistical analysis was performed using Mann-Whitney U test and Wilcoxon signed ranks test

Results: Patient characteristics and duration of surgery did not differ between groups. MAP decreased significantly in group G after the induction of anaesthesia and decreased further after tilting to head-up position ($p < 0\ 01$) followed by a significant increase after peritoneal insufflation (p <

0.01). Heart rate decreased significantly only in the E group after induction and tilting into head-up position being significantly lower compared to the preinduction value ($p < 0.05$).

Conclusion: Thoracic epidural anaesthesia prevents MAP increase after peritoneal insufflation with CO_2 during laparoscopic cholecystectomy

A.404 Epidural pneumocephalus after epidural lumbar technique

E Mateo, M D. López, E. Calabuig, S Moliner, J De Andrés, F Grau. *Department of Anesthesia, General Hospital, València, Spain*

Background and Goal of Study: We describe and discuss the physiopathology about an epidural pnemocephalus (PN) after the "loss-of-resistance" technique using an air filled syringe for identification of the epidural space.

Materials and Methods: A male patient, 76 years old, scheduled for prostatical adenomectomy Puncture and placement of an epidural catheter by loss-of-resistance with gassy plunger (Penfix 421 Braun, Germany) with the patient in sitting position. After locating the epidural space the patient felt something unpleasant like "something that ran up all over the back till the head" and pulsation pain on the temple. The Brain Tomography (BT) showed ectopical air placed in pretemporal and prefrontal spaces.

Results and discussion: The epidural space has been classically described like a space which finished at its top side at the level of the foramen magnum The critical point from the air cross from its situation in cervical epidural level to cranium epidural space, is at level of odontoid process level. The BT from this patient showed up the air passing between the duramater and the odontoid ligament. The individual variations in the composition of the epidural space could explain this particular crossing of air.

Conclusion: The epidural location from a PN after making a lumbar epidural technique is a new complication that has not been described until now. It will be necessary to do a prospective study to confirm these datum from the anatomical hypothesis about the etiopathogeny, and verify the real rate of this complication.

A.405 Jet injector compared with needle and syringe for administration of local anaesthetic

R.J. Atwater, F.K. Enneking, B.D. Bertolet *Depts of Anesthesiology and Medicine, Univ of Fla Coll of Med, Gainesville, Fla 32610, USA*

Background and Goal of Study: Jet injector systems (JIS), which use a high velocity jet of liquid to pierce the skin, were initially developed in the 1930s Little data exists comparing the efficacy of JISs with a conventional needle and syringe (NS) in delivering local anesthetic agents. This study compared the local anesthetic requirement and serum anesthetic levels of lidocaine using a JIS and a conventional NS

Materials and Methods: Following IRB approval, 30 consenting adults scheduled for elective cardiac catheterization were randomized to either the NS group (control) or JIS group. The NS group (n = 15) received 2% plain lidocaine, and the JIS group (n = 15) received a single injection (Medi-Ject Corp, Medi-Jector II) of 1 ml of 1% plain lidocaine prior to femoral cannula placement Both groups received additional 2% lidocaine from a NS, as needed for break-through pain during cannula placement. The serum lidocaine level of each patient was measured at baseline, after cannula placement, and 15 and 30 min after injection A visual analogue scale (VAS) score of the discomfort was obtained from each subject in the JIS group immediately following the injection.

Results and Discussion: The JIS subjects received significantly less lidocaine than the NS subjects (57 ± 65 mg vs 341 ± 71 mg, respectively [mean ± SD, unpaired t-test, $p < 0.001$]). The JIS did not cause significant discomfort (1.6 ± 1.7 VAS, range 0 to 5), and was reported as painless by 40% of subjects Serum lidocaine levels (μg/ml) are reported at times after injection in table

	At cannula placement	At 15 minutes	At 30 minutes
NS (n = 15)	5.4 ± 2.4	4.3 ± 1.6	5.3 ± 1.9
JIS (n = 13)	1.2 ± 0.7†	0.6 ± 0.2†	0.8 ± 0.2†

Therapeutic serum lidocaine levels are from 1–5 with >7 considered toxic. † Compared to mean NS at same time, $p < 0.05$ Data expressed as mean ± SEM for number of patients

Group means compared with one-way analysis of variance followed by Dunn's pairwise testing

Conclusion: The JIS compared to NS decreased the amount of lidocaine required for patient comfort during femoral cannula placement and resulted in lower serum lidocaine levels

This study was supported by a grant from the Baxter Healthcare Corporation.

A.406 The usefulness of colour Doppler ultrasound guided infraclavicular brachial plexus block

S. Honjo. *Department of Anesthesiology, Kyounn University School of Medicine, Tokyo, Japan*

Back ground & Goal of Study: The ultrasonography-guided nerve block has made possible to visualize the major anatomical structures (1)–(2) The aim of this clinical study was to estimate the usefulness of the color Doppler ultrasonography (CDUS)-guided modified infraclavicular brachial plexus block (m-IcBPB) (3).

Methods: After informed consent, 7 patients with persistent upper extremity pain participated in this study of the 37 CDUS-guided m-IcBPBs. The patient was placed in supine position and the arms were placed at the side Ultrasonographic examinations of the infraclavicular vessels and coracoid process were done using the linear probe (PLF-805 ST, PLF-703 ST/NT, 7.5 MHz. ECCOCEECX-SSA-340 ATM; TOSIBA, Japan) The scanning head was positioned inferior to the clavicle. The anatomic situation of the high axilla was recorded on a color printer (Tosiba TCP7700 TM; TOSIBA, Japan) After visualization of the anatomy, with the index finger palpating the coracoid process, the needle (23G–25 mm) syringe assembly was introduced medial to the coracoid process & advanced posteriorly, slightly cranially until the decreased resistance with penetration of the fascia clavipectoralis was felt on the plunger. After the thermic stimulation induced paresthesia in forearm was elicited (3), 1% mepivacaine (0.2–0.3 ml/kg) was injected Cutaneous current perception thresholds (CPT) were measured on the 2nd finger tip with neurometer (Neurometer-CPT Neurotron) before and after the m-IcBPBs.

Results: None of the patients showed hematoma, clinical symptoms of pneumothorax or needle induced neurological sequelae after the blocks. Two of the 7 patients had complete resolution of the persistent pain (CRPS) and 3/7 patients had a VAS of 5–3/10 following a series of m-IcBPBs. The mean CPTs with 5-Hz and 250-Hz stimulation were increased to greater than baseline 15 min after the m-IcBPB

Conclusion: Although further investigation is required, this clinical study suggests that the CDUS-guided m-IcBPB is easier than the method using B-mode ultrasonography, and prevents the complications and could increase the success rate of the blocks in obese patients.

A.407 Flow cytometric analysis of *in vitro* effect of bupivacaine on platelet activation

S.A. Bew, A E Bryant, G.M. Hall *St. George's Hospital Medical School, London, Italy*

Background & Goal: Extradural anaesthesia with bupivacaine reduces post-operative venous and arterial thrombosis. In addition to haemodilution, increasec lower limb blood flow and changes in fibrinolysis, the membrane stabilising and anti-leukocyte adherence effects of amide local anaesthetics which reduce platelet activation may also be important. Platelet aggregation studies show bupivacaine reduces aggregation but only at toxic doses. (1) Peak plasma concentrations 15–30 min after extradural anaesthesia are 1–2 μg/ml, toxic values are 4 μg/ml. Aggregation studies require the preparation of platelet rich plasma, but flow cytometry may be a more sensitive measure of early changes in activation. A whole blood method has been described in which fluorescent antibodies are used to label platelet membrane proteins. (2) Early activation is marked by a conformational change in the GPIIb-IIIa surface protein complex and can be measured using a polyclonal anti-fibrinogen antibody which binds to fibrinogen on the receptor surface After degranulation proteins from the alpha and lysosomal granules are expressed on the platelet surface and can be measured using CD62 and CD63 antibodies respectively.

Materials and Methods: Blood from 8 fit medication free volunteers was drawn without stasis into 1/10 volume 3.8% trisodium citrate and either labelled and analysed at once for a baseline value, or incubated at 37°C for 1 h with saline, 0.4, 2 or 10 μg/ml bupivacaine before labelling and analysis. The number of activated platelets out of a count of 5,000 was measured.

Results and Conclusions: Results were analysed using the Wilcoxon signed rank test. Samples labelled with the anti-fibrinogen antibody showed a significant increase in activation when incubated with saline compared with baseline (p = 0.01) Incubation with 0.4 μg/ml bupivacaine elicited a non significant decrease in activation, but incubation with 2 and 10 μg/ml resulted in significantly reduced activation, (p = 0.05). There was no significant change in activation under any of the study conditions using the CD62 and CD63 antibodies Bupivacaine at concentrations found after extradural anaesthesia decreases early platelet activation, but does not alter degranulation

A.408 The electroencephalographic effects of spinal anaesthesia

A.P. Morley, T.G. Short. *Dept Anaesthesia and Intensive Care, Chinese University of Hong Kong, Hong Kong, China*

Background and Goal of Study: During surgery, the electroencephalographic (EEG) features of combined regional (RA)/general (GA) anaesthesia differ from those of GA alone [1] To investigate the independent effects of sensory blockade, we compared EEG variables and sedation scores from patients having spinal anaesthesia (SA) with those occurring over time in a control group.

Materials and Methods: 17 patients, aged 18-65, undergoing elective surgery were studied preoperatively An SA group (n = 8) was compared with a control group (n = 9). Median frequency (MF), 95% spectral edge frequency (SEF), bispectral index (BIS) and relative percentage power in EEG frequency bands (delta 0–3.75, theta: 4 0–7.75, alpha· 8.0–13.5, beta: >13 75 Hz) were recorded continuously from frontotemporal electrodes with an Aspect A-1000 EEG monitor. Data were downloaded to a computer for later analysis Sedation scores[2] were recorded every 5 minutes. Data were collected for 30 min (S1). SA patients then received 3 ml intrathecal bupivacaine 0.5%. Hypotension was treated with fluid. 30 min after the end of S1, data collection was recommenced for 30 min (S2) Median sedation scores and mean EEG values were calculated in each patient for S1 and S2 Median group sedation scores were compared by Wilcoxon rank-sum or signed-ranks tests, mean group EEG data by t tests, paired and unpaired.

Results and Discussion: Sedation scores did not change with time or SA EEG data is shown below (mean (SD)).

	Control group (n = 9)		SA group (n = 8)	
	S1	S2	S1	S2
SEF Hz	17 6 (5 6)	17 5 (4 9)	18 1 (5 5)	23 4 (2.9)*†
MF Hz	4.0 (2 1)	3 9 (1 7)	3 9 (1.6)	6 3 (3 6)*†
BIS	92 6 (4.1)	92 7 (3 5)	92 6 (3 5)	96 2 (1 3)*†
alpha%	13 4 (8 6)	14 2 (8 4)	14 2 (9 3)	15 1 (8 2)
beta%	12 3 (8 0)	11 7 (6.2)	12 2 (6 4)	24 5 (13 9)*†
theta%	16 8 (4 4)	15 3 (4.2)*	16 0 (3 0)	13 9 (3 9)
delta%	57 5 (15 8)	58 9 (14 7)	57 7 (14 9)	46 5 (14 3)*†

Significant differences at $p < 0$ 05· * within group between S1 and S2, †· between groups for S2

Conclusion(s): SA does not affect sedation scores. EEG changes differ from those occurring over time. Their contribution to EEG effects of combined RA/GA is unclear.

A.409 Thoracic epidural anaesthesia and GUT mucosal perfusion assessed by gastric tonometry and laser Doppler flowmetry in coronary artery surgery

D J. Turfrey, M J. Hodson, N.P. Sutcliffe. *Glasgow University & HCI Medical Centre, UK*

Objectives: To assess the effect of thoracic epidural anaesthesia in patients undergoing coronary artery surgery on gastric intramucosal pHi during surgery and in the first 8 hours postoperatively and to see how this varies in comparison to blood flow measured using laser doppler flowmetry techniques.

Methods: 30 patients undergoing routine surgery were randomised prospectively to either receive thoracic epidural anaesthesia with bupivacaine and clonidine in conjunction with GA or GA alone. pHi was measured continuously using the Tonocap (Tonometrics, Finland) and recorded at 9 time points. Serum lactate was measured at 4 time points during the study period Laser Doppler flux was measured continuously (Moor Instruments, UK)

Results: The groups were well matched in terms of demographic and operative data. There was no significant difference between the two groups in pHi during the study period. However, pHi fell during bypass compared to prebypass levels and mean values of less than 7 3 were recorded in both groups Serum lactate was significantly raised in the non-epidural group 8 hrs post admission to ITU (p = 0.047). CO2 gap was significantly worse in the epidural group at 8 hrs post ITU. We found no significant difference between standard pHi and pH gap between the two groups. There were no deaths or major complications in either group. Laser doppler flux measurements initially fell at the start of bypass in both groups but then increased during rewarming and into the postoperative period indicating increased mucosal blood flow.

Discussion: TEA does not appear to alter the gastric mucosal perfusion as measured by tonometry or laser doppler flowmetry in this group of patients However, the number of patients studied were small and trends between the two groups may become significant if larger numbers of patients were studied pHi worsened in both groups to levels which have been previously described as critical, during and after the bypass period pHi is an indirect measure of gut blood flow and the changes in mucosal blood flow seen with the Laser Doppler Flowmetry technique suggest an increase in perfusion during rewarming and in the postoperative period This was not associated with improved pHi and may be due to either 1) an inappropriate redistribution of blood at the mucosal level 2) the development of an oxygen debt during the period of hypothermia on bypass which remains in the postoperative period despite the increase in mucosal blood flow

A.410 Comparison of two anaesthetic procedures for removal of angioplasty introducers

A Rodríguez, O. Campaña, J C. Diz, J M Rodríguez, J. Cortiñas, P. Otero, J. Alvarez. *Hospital Xeral of Galicia, Clinico Universitario, Santiago of Compostela, Spain*

Background: Removal of femoral introducers used in PTCA (Percutaneus Transluminal Coronary Angioplasty) is seldom accompanied by bradyarrhythmias (that require atropine administration), important nuisances in the compression area and even angina We want to investigate if there are differences in hemodynamics, occurrence of arrhythmias, use of antiarrhythmic drugs and patient's comfort during introducers removal using two different anaesthetic procedures· femoral nerve blockade and local infiltration of the area

Material & methods: Following Ethics Committee approval 29 consenting patients submitted to scheduled PTCA were randomly enrolled and divided into two groups The femoral nerve blockade was the anaesthetic technique employed in 17 patients. This is a common procedure for knee arthroscopy (1) or surgery of fractured shaft of femur (2). The nerve was located with a peripheral nerve stimulator using a standard intensity of 2 5 mA. After the localization 25 ml of 1% lidocaine solution were injected, and introducers were removed 30 minutes later In the local infiltration group, 15 ml of 1% lidocaine were injected subcutaneously around the introducers. We studied distribution and quality of the blockade, occurrence of arrhythmias, necessity of antiarrhythmics, ischemic events, blood pressure (BP) and heart rate (HR) (basal and every minute after the removal) and degree of the patient's comfort. Statistical tests included t Student, Chi square and U Mann-Whitney

Results: Both groups were similar in age and sex distribution. Only four patients had arrhythmias (two in each group): three bradyarrhythmias (two of them requiring atropine) and the other premature ventricular contraction. No patient had angor. There were not statistically significant differences between both groups in any of the variables analyzed.

Discussion: Based on these results, both procedures can be chosen indistinctly, although the simplicity and brevity of the local infiltration probably makes it the elective anaesthetic technique for removal of PTCA introducers.

A.411 Subarachnoid block and computerized sedation: haemodynamic profile

M. Sánchez-Castilla, J. López-Martínez, M S A de Lis, P. Rodriguez-Tato. *Hospital "Severo Ochoa" Madrid, Spain*

Goal: To assess whether a computerized infusion with propofol achieves reliable sedation with stable hemodynamics.

Patients and Methods: Forty premedicated patients undergoing scheduled surgery under a subarachnoid block were randomly ascribed to two groups no sedation and target controlled infusion (TCI-Diprifusor®). Both groups matched for age (41 ± 16), height (169 ± 9), weight (72 ± 13) bupivacaine dosage (13 ± 2), and ASA. (Median ± standard deviation) No inotropics were required Heart rate, noninvasive blood pressure, S_pO_2 and ET CO_2 were recorded at baseline, after the block, at incision and at the end. Informed consent was obtained. Statistics: t-test Linear regression

Results: An observer's assessment of alertness/sedation[2] not higher than 3 was achieved with predicted plasma propofol median concentrations 1 4 μg/ml with a range of 0.6–2.9[1] in TCI group with a median of 3.2 changes/patient. No statistical differences in blood pressure were found between baseline values and throughout the procedure, nor between groups but heart rate was lower whilst on propofol. Blood pressure at the incision correlated closely with the final measurement in non-sedated patients (r = 0.84) and in the TCI group whenever the length of the procedure was over 60′ (r = 0.94)

	Baseline	Block	Incision	End
TCISBP	148 ± 25	128 ± 23	119 ± 20	128 ± 14
TCIDBP	85 ± 11	77 ± 12	66 ± 15	68 ± 13
TCIHR	83 ± 20	77 ± 12	70 ± 13	73 ± 20
NSSBP	141 ± 31	129 ± 20	130 ± 16	127 ± 10
NSDBP	82 ± 13	71 ± 9	74 ± 28	68 ± 13
NSHR	79 ± 21	105 ± 15	96 ± 12**	97 ± 10*

**p < 0 01, *p < 0 05

Conclusions: A TCI of propofol provides easy control of sedation and does not alter blood pressure in SA block

A.412 Sedation during regional anaesthesia for orthopaedic surgery: propofol *vs* remifentanil

F. Consiglio, L. Sero, E. De Luca, F Golia, P. Piccinillo, A Grella. *II Università degli Studi di Napoli-Facoltà di Medicina e Chirurgia. Istituto di Anestesia, Analgesia, Rianimazione e Terapia Intensiva "N Cocchia". Dir. Prof. A. Grella, Italy*

The use of sedation during R. A. can provide enhanced patient comfort while optimazing intraoperative conditions (1). The aim of this study is to compare the sedative effects of Propofol and Remifentanil (2) in 40 patients undergoing elective orthopaedic surgery.

Methods: Patients, ASA I–II, 37 years mean age, were randomized in 2 groups of 20 each. ECG, B.P., H.R., R.R. and SpO_2 were monitored throughout the procedure. The R A techniques, biblock and brachial plexus block, were comparable in both groups. After Intravenous Atropine, group A received Propofol (1.5 $mg{\cdot}Kg^{-1}{\cdot}h^{-1}$), while group B Remifentanil (0.1–0.2 $mcg{\cdot}Kg^{-1}{\cdot}min^{-1}$), with a continuous infusion pump, to maintain sedation all over the procedure, with a constant rate of Propofol infusion, while Remifentanil's rate was subsequently titrated due to the respiratory and haemodinamic effects (bradycardia and hypotension), for the better patient comfort. Sedation's level was rated before the block, at 15 m′ of intervals and at the end of the procedures, on a five point sedation scale (from 1 = fully awake, to 5 = unrousable to mild physical stimulation) (3).

Results: Sedation vanished in 1–2 m′ after the infusion stopped Nobody among the 2 groups had respiratory or haemodinamic complications Similar sedative effects were demonstrated, even if Remifentanil was a better analgesic adjuvant when the blocks were uncomplete; sedation's level was conditioned by patients' age and O.R.'s noisy: no one has been fully awake or unrousable to mild physical stimulation; 15 pts (75%) in group A and 17 (82%) in group B were lightly sedated and rousable to spoken commands; only 5 (25%) in group A and 3 (18%) in the other one were rousable to mild physical stimulation (earlobe tug). All the pts left the O.R. completely awake and no PONV occurred; fluids and analgesics, as required, could be taken orally almost immediately.

Conclusions: Propofol and Remifentanil give both a good sedation during R.A. Remifentanil offers us an analgesic effect too, but to achieve the desired results it's necessary a vigilant continuous monitoring and a careful dose titration, which is sometimes difficult, especially for young patients.

A.413 Sedation during spinal anaesthesia: comparison of haemodynamic, anxiolytic and amnesic effects of propofol and midazolam

A Marşan, S. Şen, T. Gumuş, H. Gümuş, N Göğuş, C Aksu. *Department of Anaesthesiology, Numune Hospital, Ankara, Turkey*

Introduction: Supplementary sedation for spinal anaesthesia can enhance patient comfort and increase acceptance of this technique. The aim of this study was to compare the haemodynamic, anxiolytic and amnestic effects when either midazolam or propofol was given by subanaesthetic infusion to provide sedation as an adjunct to spinal anaesthesia.

Method: After Informed consent and approval by the Ethics Committee 45 patients ASA I–II, undergoing surgical procedures with spinal anaesthesia were randomly assigned to one of three groups. Control (Group C) received no sedative-hypnotic agent; Propofol (Group P) received a loading dose of 1 mg/kg followed by an infusion of 4 mg/kg/hr; Midazolam (Group M) received a loading and infusion dose of 0 1 mg/kg. The infusion rates were adjusted to maintain an appropriate level of sedation (level 3–4) on a five-point sedation scale The sedative infusion was stopped 10 minutes before the anticipated end of the procedure. The sedation score, the systolic, diastolic, mean arterial pressures (SAP, DAP, MAP), heart rate (HR), respiratory rate (RR) and oxygen saturation (SaO_2) values were recorded before spinal block, after spinal block and at 5-minute intervals throughout the surgical procedure Visual analogue scales (VAS) were used to assess pre- and postoperative anxiety. In the Recovery Unit, the times taken from the end of the infusion for patients to open their eyes on command and to given correct responses to the questions about name-place-time were noted. To assess intraoperative recall, a simple picture was shown to the patients by rousing them during the operation.

The results were analyzed statistically using Kruskal-Wallis, ANOVA, Mann Whitney U and Chi-square tests.

Results: The three groups were similar demographically. There were statistically significant decreases in SAP, DAP and MAP values in Group P where the decreases were statistically insignificant in Group M There were statistically significant increases in respiratory rates in Group P and Group M beginning from the 5th and 15th minutes of infusion respectively Postoperative anxiety scores of Group P and Group M were statistically lower than Group C ($p < 0.05$). Amnesia was significantly greater with midazolam (80%).

Conclusion: Both propofol and midazolam by intravenous infusion provide satisfactory sedation as an adjunct to spinal anaesthesia. Midazolam, for its amnestic and stable haemodynamic effects and propofol, for its rapid recovery are evaluated as preferred agents for supplementary sedation

A.414 Haemodynamic effects of general anaesthesia and intravesical bupivacaine for endoscopic bladder surgery

L. Iyilikçi[1], D Çatal[1], E. Gokel[1], M Güzelsoy[2], Ü Onat[1], C. Güler[2], Z. Kırkalı[2]. *DEÜTF School of Medicine Departments of [1]Anesthesiology and [2]Urology Inciraltı 35340, İzmir, Turkey*

The majority of endoscopic procedures are performed under spinal or general anesthesia Lidocaine gel can be used locally for topical urethral anesthesia However, this is not appropriate for endoscopic bladder surgery (1). In this study we compared the hemodynamic effects of intravesical bupivacaine and general anesthesia.

Material & Methods: After Institutional approval, fifty ASA II, III patients undergoing endoscopic bladder surgery were recruited (HR) (beats/min) was recorded and (MAP) (mmHg) monitoring was performed. Patients were randomly allocated into two groups. Group I: Anesthesia was obtained by giving 10 cc of 2% lidocaine hydrochloride gel in the urethra and instillation of 60 cc of 0.5% bupivacaine hydrochloride via a Foley catheter. Group II: Induction of anesthesia is obtained with 2–3 mg/kg propofol, 0.5 mg alfentanyl IV and maintained with N_2O %50 in 50% O_2 and 2 mg/kg propofol infusion MAP and HR measurements were recorded every 5 minutes. The data were statistically analyzed with paired-t test.

Results: Demographic data and duration of operation were similar in both groups (Table 1). MAP and HR were not different compared to baseline in group I, whereas they were significantly reduced in 5 and 10 minutes in group II ($p < 0.05$). Check cystoscopies together with selected area biopsies were performed without any pain to the patient in both groups.

Hemodynamic parameters

MAP (mmHg)	Baseline	5 min	10 min
Group I	111 8 ± 3 8	108 ± 3 2	109 2 ± 3 2
Group II	107 8 ± 2 5	76.6 ± 1 2*	78 2 ± 1 5*

HR (beats/min)	Baseline	5 min	10 min
Group I	74.1 ± 2 8	73 6 ± 3 2	73 1 ± 0.8
Group II	76 0 ± 1 4	63 5 ± 0 6*	63 1 ± 0 8*

Conclusions: Our data show that lidocaine gel for urethral anesthesia and 60 cc of 0 5% bupivacaine hydrochloride instillation into the bladder provide adequate anesthesia and analgesia for endoscopic bladder surgery Intravesical bupivacaine anesthesia causes less hemodynamic disturbances compared to general anesthesia These observations may greater impact in elderly and high risk patients

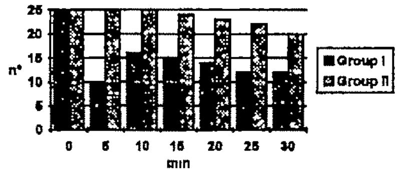
A.415 Urapidil for the treatment of postepidural shivering. A preliminary study

S. Sia *Department of Anaesthesia and Intensive Care, Centro Traumatologico Ortopedico, Firenze, Italy*

Background & Goal of Study: there is evidence that both drugs acting on α-adrenergic and on 5-hydroxytryptamine (5-HT) receptors reduce post-anaesthetic shivering[1]. Urapidil (U), an antihypertensive drug acting on α^1-adrenergic and 5-HT_{1A} receptors, suppressed cold induced shivering in volunteers[2]. This study investigated the efficacy of U in suppressing post-epidural shivering.

Materials and Methods: 50 healthy patients, aged 18–45, who developed shivering after epidural anaesthesia, were randomly allocated into two groups of 25 Group I received i.v U 25 mg, group II received a saline bolus Shivering was assessed just before treatment (0 min = baseline) according to a three-point scale: 0 = no shivering, 1 = moderate, 2 = severe Shivering grade, systolic arterial pressure and heart rate were assessed every 5 min for a period of 30 min starting from baseline Hypotension was defined as a 20% reduction in SAP in relation to baseline value. Data were analysed using t-test, Mann-Whitney U-test and chi-squared test as required.



Results: U was more effective than placebo in suppressing shivering (P < 0 001 at 5 min; P < 0.005 at 10 min, P < 0 01 at 15, 20 and 25 min, P < 0 05 at 30 min) (see fig 1). The severity of shivering was significantly lower in group I at 5 and 10 min (p < 0 05). In group I six patients recommenced shivering after they had stopped Five patients in group I and none in II had hypotension (P = 0.059.

Conclusions: U 25 mg was effective in treating post-epidural shivering However 30% of the patients who had stopped after U administration, recommenced shivering within 5 min A non significant trend toward a greater incidence of hypotension was recorded in group I Larger studies are needed to evaluate the benefits of this method.

A.416 Incidence of hypotension during thoracic epidural anaesthesia combined with general anaesthesia: fentanyl plus etomidate *vs* ketamine plus midazolam

F. Galindo, C. Ezquerro, C. Rivera, B. López *Servicio de Anestesiología y Reanimación, Hospital Puerta de Hierro, Madrid, Spain*

Background and Goal of Study: Thoracic epidural anesthesia (TEA) combined with general anesthesia (GA) can produce hypotension, the incidence of which may be related, among other factors, to the type of GA Ketamine and etomidate preserve the efferent sympathetic nerve activity and autonomic reflex function; in addition, ketamine produces sympathetic stimulation We proposed to determine whether induction of GA with a combination of ketamine plus midazolam was associated with lower incidences of hypotension and bradycardia than induction with fentanyl plus etomidate

Material and Methods: A series of 82 adult patients, ASA class II–III, who were to undergo abdominal surgery was studied All of the patients underwent placement of a thoracic epidural catheter (D_6–D_8) and received 6–12 ml of 2% lidocaine, continued at a rate of 4–9 ml/h. The patients were prospectively randomized to Group I (n = 41), in whom anesthesia was inducted by ketamine (2 mg/kg) plus midazolam (0 1 mg/kg) plus vecuronium (0.15 mg/kg), and Group II (n = 41), who received etomidate (0 2–0 3 mg/kg) plus fentanyl (5 μg/kg) plus vecuronium (0 15 mg/kg) Maintenance was achieved with 50% O_2 plus 50% air plus 0.5–1% isoflurane in both groups. Heart rate (HR) and systolic blood pressure (SBP) were measured noninvasively once every minute until intubation and every 3 minutes thereafter until skin incision We defined 3 levels of hypotension – SBP < 100 mmHg, SBP < 90 mmHg and SBP < 80 mmHg – as well as bradycardia HR: < 50 bpm. The data were analyzed using the χ^2 test and comparison of proportions and the χ^2 test with Yates' correction was used when the expected frequency was under 5% A p value of less than 0 05 was considered to indicate statistical significance

Results and Discussion: The observation period had a minimum duration of 40 minutes.

	SBP < 100 mmHg	SBP < 90 mmHg	SBP < 80 mmHg	HR < 50 mmHg
Group I %	26.8	17	9 7	7 3
Group II %	70 7	29 2	4 8	29 3
p value	<0 05	>0 05	>0 05	<0 05

Conclusions: In TEA combined with GA, induction with ketamine plus midazolam is associated with a lower incidence of mild hypotension and bradycardia than induction with etomidate plus fentanyl

A.417 Pharmacokinetics of epidurally administrated liposomal bupivacaine in humans

V. Umbrain, S Van Melkebeke, J D'Haese, F Legros, F. Camu
Department of Anaesthesiology, Free Flemish University of Brussels Medical Center, Belgium

Introduction: Liposomes associated with aminoamides, prolong sensory anesthesia and reduce peak plasma levels of aminoamide when injected epidurally in animals (1–4). To determine the validity of this statement in humans, we evaluated the effect of liposome encapsulation of bupivacaine on the course and extent of systemic arterial concentrations of bupivacaine after epidural administration of liposome encapsulated bupivacaine

Methods: Liposomes associated bupivacaine were prepared in sterile and aseptic conditions as described before (5). Following approval by the University Committee on Human Research, 14 patients (ASA I–III) scheduled for abdominal surgery, received an epidural catheter inserted to at L2 level and a 3 ml test dose of xylocaine 2% with 1/200 000 adrenaline Then, 10 ml of either bupivacaine 0 5% (group BUPI) (n = 7) or liposome associated bupivacaine 0 5% (group LIPO) (n = 7) were injected epidurally After a 30 min observation period, a general anesthesia was started and surgery allowed to proceed Meanwhile, plasma arterial blood samples were taken before injection at 5, 10, 15, 30, 45 min and at 1, 2, 3, 4, 6, 12 and 24 h to determine plasma bupivacaine levels Plasma bupivacaine levels were determined with HPLC (detection limits of 10 ng/ml) All data are expressed as mean value ± SD. Differences between groups were identified with ANOVA and MWU-test. P < 0 05 values were considered statistically significant

Results: Both groups demonstrated similar demography The profile of the bupivacaine concentrations revealed a lower peak concentration in group LIPO (mean 351 ± 135 ng/ml; range 166–562 ng/ml) vs group BUPI (mean 554 ± 126 ng/ml; range 450–757) $T_{max-Lipo}$ (28 ± 12 min, range 15–45 min) was delayed vs $T_{max-Bupi}$ (10 ± 3 min, range 5–15 min) Plasma levels of bupivacaine in group LIPO revealed an increased terminal decline half-life (451 ± 210 min vs 327 ± 145 min).

Conclusion: This human study demonstrated that after epidural administration of liposomes associated bupivacaine peak plasma levels were reduced and T_{max} delayed The current formulation is associated with a prolonged release of bupivacaine

PHARMACOLOGY

A.418 Intubating characteristics and duration of clinically effective block after two different doses of cisatracurium

D. King, P. Bunting, N. Huggins, P Mangat, J. Saddler, J Canning *UK Cisatracurium Study Group, UK*

Background and Goal of Study: Cisatracurium is one of ten stereoisomers of atracurium, being more potent with a mean ED95 in adults during opioid anaesthesia of 0.05 mg/kg (1) This study simulated routine clinical practice and compared the time to satisfactory intubating conditions and the duration of clinical block of two different doses of cisatracurium

Materials and Methods: 95 healthy adult patients were entered into this randomised, open-label study. Following premedication, anaesthesia was induced with propofol and fentanyl; patients were allocated to receive cisatracurium either 0.10 mg/kg or 0.15 mg/kg, and anaesthesia maintained with N_2O in oxygen supplemented with isoflurane.

Intubation was attempted 2 minutes after administration of cisatracurium and graded according to standard criteria. Neuromuscular transmission was monitored by tactile evaluation of the adductor pollicis response to train-of-four (TOF) stimulation. If required, further doses of 0.03 mg/kg cisatracurium were given on the reappearance of the third response to TOF stimulation. Recovery from block was spontaneous or pharmacologically augmented at the investigators' discretion, and was assessed using a combination of clinical criteria and tactile response to TOF

Results and Discussion: At the first intubation attempt (median time 2 minutes in each group) 42 (91%) of patients in the 0.10 mg/kg group and 47 (98%) of patients in the 0.15 mg/kg group were satisfactorily intubated. There was no significant difference between treatments when assessing the time to intubation; however, the first intubation grades suggested that patients receiving 0.15 mg/kg had better conditions than patients receiving the 0.10 mg/kg dose ($p = 0.002$). Clinical duration of block, as measured by the return of the third response to TOF stimulation, was significantly shorter in the 0.10 mg/kg group than in the 0.15 mg/kg group (median time 37 minutes vs 47 minutes respectively, $p < 0.001$). There were no reports of inadequate reversal, either spontaneous or augmented, and no serious adverse events were described.

Conclusions: The intubating conditions and duration of clinical block support a dose of 0.15 mg/kg, which provides satisfactory intubating conditions at two minutes and approximately 45 minutes of clinical block, which can either be allowed to recover spontaneously or may be readily reversed pharmacologically, once signs of spontaneous recovery are present.

Study funded by a research grant from Glaxo Wellcome

A.419 Duration and recovery profile of cisatracurium after suxamethonium during propofol and isoflurane anaesthesia

T.J. Gan, I. Sanderson, B. Ginsberg, R. Alexander, H.E. El-Moalem, K Weatherwax, P. Glass *Department of Anesthesia, Duke University Medical Center, Durham, NC 27710, USA*

Background: The duration to 25% recovery following an intubating dose of cisatracurium (CA) 0.2 mg/kg is about 1 hr with nitrous-narcotic technique (1) and even longer with inhalational agent. There is paucity of data on the duration of action of CA when administered after succinylcholine (S) This study determines the duration of action and recovery profile of small doses of CA following S during propofol and isoflurane anesthetics.

Methods: Forty ASA 1 & 2 adult patients having elective surgery with general anesthesia lasting longer than 90 min were enrolled after IRB approval and written informed consent. All patients received midazolam 1–3 mg as premedication. General anesthesia was induced with propofol 1–2 mg/kg. Datex 221 NMT was used to record the response of the adductor pollicis after supramaximal stimulation of the ulnar nerve. A baseline EMG was obtained after induction An intubating dose of S 1.5 mg/kg was administered The tracheal was intubated when the first twitch of the evoked train-of-four (TOF) reached ≤10% of control Spontaneous recovery from neuromuscular blockade was allowed to occur until the first twitch (T1) returned to 25% of control. Patients were then randomized to receive CA as follows. Group 1: 0.025 mg/kg (0.5XED95); Group 2: 0.05 mg/kg (ED95); Group 3: 0.05 mg/kg (ED95) and Group 4: 0.1 mg/kg (2XED95). Patients in Groups 1 and 2 were maintained with isoflurane 1–2%, 66% N_2O in O_2 while patients in Groups 3 and 4 were maintained with propofol 80–160 μg/kg/min, 66% N_2O in O_2. Temperature was maintained above 35°C and end-tidal CO_2 was maintained between 30–40 mmHg The TOF evoked EMG was recorded at 10 s intervals. The time for the evoked EMG to spontaneously return to 25, 50 and 75% of the original baseline was noted. Descriptive statistics and Kruskal-Wallice test were performed. A $p < 0.05$ was considered statistically significant.

Results: There were 10 patients in each group. Patient demographics were similar between groups. In group 1 (0.025 mg/kg), only 3 out of 10 patients had $T1 < 25\%$. Table 1 shows time to lowest T1 and the recovery profile.

Time to	Isoflurane Groups		Propofol Groups	
	1/2XED95	ED 95	ED 95	2XED95
Max block*	6.1 ± 2.1	5.3 ± 3.15	4.6 ± 2.2	3.4 ± 2.2
T1 = 25%*	N/A	24.5 ± 10	21.3 ± 9	40.2 ± 7
T1 = 50%*	N/A	33.8 ± 14	27 ± 9	47.5 ± 8
T1 = 75%*	11 ± 8.3	42.2 ± 18	32.8 ± 4	59.7 ± 19
T1 25–75%	N/A	19.4 ± 4.2	16 ± 8.7	19.6 ± 8.5

All times are in min. Mean ± SD * = $p < 0.01$

Conclusions: CA 0.05 mg/kg (ED95) provides 20–25 min. of neuromuscular blockade after intubating dose of S. CA 0.025 mg/kg (1/2XED95) is an inadequate dose in this setting. Doubling the dose of CA resulted in twice the duration of action under propofol anesthetic. The recovery profile of CA is predictable following S during isoflurane and propofol anesthetic

A.420 Effects of atracurium in thymectomy for myasthenia gravis

H.S. Yang, Y. Choi, D M Lee. *Department of Anesthesiology, Asan Medical Center, College of Medicine, University of Ulsan, Seoul, Korea*

Background and Goal of Study: Myasthenia gravis is an autoimmune neuromuscular disorder that shows increased sensitivity to nondepolarizing muscle relaxants. Atracurium is eliminated by Hofmann elimination and ester hydrolysis. We studied the onset and duration of atracurium in patients with myasthenia gravis.

Materials and Methods: Ten patients undergoing thymectomy for myasthenia gravis and ten patients of ASA class I–II without liver, kidney and neuromuscular disease for orthopedic surgical procedures were assigned to two groups: control and myasthenia gravis.

Anesthesia was induced with thiopental and maintained with inhalation of N_2O-O_2 (1:1) and isoflurane (0.5–1.5 vol%). Atracurium (0.5 mg/kg) was given as a muscle relaxants and then intubation was performed after twitch response was depressed more than 80%. Neuromuscular relaxation was assessed by TOF (T1) at the adductor pollicis with supramaximal stimulation of ulnar nerve at 2 Hz every 12 seconds. The onset and duration of 5, 25, 50, 75% recovery time of T1 and recovery index were recorded.

Results & Discussion: Onset of block was shortened and recovery time of 5, 25, 50, 75% and recovery index were prolonged in patients with myasthenia gravis.

Onset, Duration and Recovery Index of Atracurium

	Control	Masthenia Gravis
Onset time (min.)	3.4 ± 1.4	1.3 ± 0.3*
Recovery time (min.)		
5%	33.2 ± 8.0	65.0 ± 31.6*
25%	42.1 ± 9.0	72.2 ± 38.3*
50%	49.9 ± 10.8	94.2 ± 45.8*
75%	58.6 ± 12.9	112.8 ± 59.9*
Recovery index	16.4 ± 5.6	35.6 ± 33.2*

Mean ± S.D., *$p < 0.05$ Compared with control group

Conclusions: Atracurium in the patients with myasthenia gravis induced rapid onset and prolonged recovery time of 5, 25, 50, 75% and recovery index

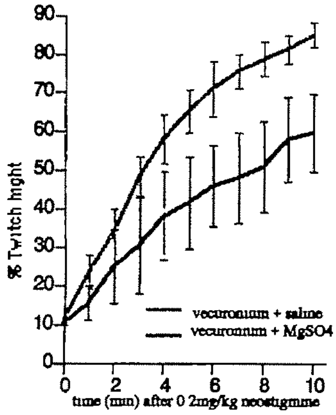
A.421 Antagonism of neuromuscular block after magnesium sulphate pretreatment

T Fuchs-Buder, S. Soltez, E. Tassonyi[1]. *Department of Anaesthesia and Critical Care University of Saarland, Homburg/Saar, Germany; [1] University of Geneva, Geneva, Switzerland*

Background: Magnesium sulphate ($MgSO_4$) may be given in the perioperative period for several reasons (1). $MgSO_4$ prolongs clinical duration and delays recovery of vecuronium neuromuscular (NM) block (2). Thus, residual paralysis occurs in this patient population (3) No prospective data about antagonisation of vecuronium NM block when used together with $MgSO_4$ are available. This study aims to investigate the impact of neostigmine (N) on vecuronium NM block with and without $MgSO_4$ pretreatment.

Patients & Methods: After ethics committee approval and informed consent, 20 patients ASA I–II were included and randomly assigned to one of two groups receiving either 60 mg/kg $MgSO_4$ or saline (n = 10 in each). In both groups anaesthesia was induced by thiopentone (5 mg/kg), fentanyl (2 μg/kg) & vecuronium (0.1 mg/kg), maintained by isoflurane (1%) and N_2O/O_2. No further muscle relaxant were given. NM blockade was assessed by electromyography (Relaxograph®). Once the NM block recovered to a twitch height (TH) of 10%, patients in both groups received N (0.02 mg/kg) and recovery of NM block assessed (TH) once a minute over 10 min. Between group comparison of the respective TH values was made using a Mann-Whitney *U* test, significance was set at $P < 0.05$.

Results: The response of TH after N was less pronounced in the $MgSO_4$ group When compared to the control group, this difference was significant over the whole study period (10 min).



Conclusion: $MgSO_4$ led to an attenuation of neostigmine-induced recovery of vecuronium-NM block (Fig 1). This may be the result of prolonged recovery of NM block after $MgSO_4$ (2) or a $MgSO_4$ induced decrease of the neostigmine response.

A.422 Spontaneous or neostigmine-induced recovery after three maintenance doses of Org 9487

K.C. McCourt, R K. Mirakhur, Carolyn Kerr, H. Sparr[1]. *Department of Anaesthetics, The Queen's University of Belfast, Belfast BT9 7BL, N Ireland, [1]Leopold-Franzens-Universität, Innsbruck, Austria*

Background: Initial studies with Org 9487, a new short-acting aminosteroidal muscle relaxant, have suggested that an intubating dose of 1 5 mg kg^{-1} may be antagonised rapidly with neostigmine within 2 min of administering Org 9487 [1]. We have undertaken a study comparing recovery after 3 maintenance doses or a 30 min infusion of Org 9487, or after 2 maintenance doses of rocuronium with and without neostigmine after an initial bolus of Org 9487. The results of the 3 maintenance doses of Org 9487 are presented here.

Methods: Thirty patients were anaesthetised with propofol 1.5–2 5 mg kg^{-1} and alfentanil 30 $\mu g\ kg^{-1}$ followed by propofol and alfentanil infusions and 60% nitrous oxide in oxygen. The ulnar nerve was stimulated with supramaximal train-of-four (TOF) stimuli and the force of contraction of the adductor pollicis recorded All patients were to receive an intubating dose of Org 9487 1.5 mg kg^{-1} and 3 maintenance doses of 0.5 mg kg^{-1} each time the T_1 (the first response in the TOF) recovered to 25% Patients were allocated at random to receive no reversal (Group I) or neostigmine 0.05 mg kg^{-1} (Group II) at T_1 to 25% after the last dose The times of recovery of TOF ratio to 0 8 and the recovery indices (RI, T_1 25–75%) were recorded

Results and Discussion: The mean (SD) Dur_{25} (time to recovery of T_1 to 25%) of the initial 1 5 mg kg^{-1} dose was 16.8 (4.0) min (n = 26). Dur_{25} of the 3 successive maintenance doses increased significantly from 12.2 (3.4) min (n = 26), to 14 0 (4 0) (n = 26), and 15.9 (5.9) min (n = 25) (P < 0 01, one sided Page's test) Administration of neostigmine on recovery of T_1 to 25% after the last maintenance dose resulted in significantly shorter times to TOF ratio of 0.8 and the RI (Table 1; P < 0 01; t test with Welch's correction)

Recovery times (min) (mean (SD))

	T_1 25%-TOF 0 8	RI
Group I (n = 11)	72 4 (16 5)	24 5 (13 6)
Group II (n = 14)	9.9 (4 5)	3 6 (1 8)

Conclusion: The results from the present study suggest that repeat doses of Org 9487 are associated with an increase in duration of action and slow spontaneous recovery compared to a single dose [1] Administration of neostigmine at T_1 of 25% results in a rapid reversal.

A.423 Action duration of atracurium and vecuronium in renal transplantation

H.S Yang, D H. Park, D M. Lee *Department of Anesthesiology, Asan Medical Center, College of Medicine, University of Ulsan, Seoul, Korea*

Background and Goal of Study: Atracurium is eliminated by Hofmann elimination and ester hydrolysis, with minimal renal and hepatic excretion Vecuronium is less dependent on the renal function than other steroid type neuromuscular blockers. But the action duration of vecuronium is prolonged in renal failure. The purpose of this study is to compare the differences of the effects of atracurium and vecuronium in patients with and without renal function

Material and Methods: Forty patients with normal renal function and 40 patients with chronic renal failure were assigned to one of four groups. atracurium-normal (n = 20, AC), atracurium-renal failure (n = 20, AK), vecuronium-normal (n = 20, VC), vecuronium-renal failure (n = 20, VK) Anesthesia was induced with thiopental and maintained with inhalation of N_2O (50%) and isoflurane (0 5–1 5vol%) Atracurium (0 5 mg/kg) or vecuronium (0 1 mg/kg) was given as a muscle relaxant and then endotracheal intubation was performed after twitch response was depressed more than 80%. Neuromuscular blockade was assessed by TOF at the adductor pollicis with supramaximal stimulation of ulnar nerve The onset time, duration of 5, 25, 50, 75% recovery time and recovery index were recorded.

Results & Discussion: Onset of block was not different among four groups. Recovery time of 5 25 50, 75% and recovery index were significantly longer in the both renal failure groups. Action duration in renal failure were not different between atracurium and vecuronium groups

Comparison of the onset time, recovery time and recovery index of the atracurium and vecuronium

	Atracurium		Vecuronium	
	AC	AK	VC	VK
Onset time (min)	2 9 (1 2)	2 9 (1.3)	2 9 (0 5)	2 5 (0 6)
Recovery time (min)				
5%	34 0 (10 8)	43 8 (20 4)*	26 2 (3 7)	54 9 (22 4)#
25%	42 6 (12 9)	60 7 (23 6)*	33 9 (5 4)	77 1 (33 5)#
50%	50 0 (15 6)	72 5 (25 8)*	38 9 (9)	89 6 (39 5)#
75%	55 7 (20 4)	85 0 (28 9)*	44 8 (9 6)	100 6 (39 0)#
Recovery Index	15 1 (8 4)	24 8 (13 4)*	10 9 (5 5)	25 6 (9 8)#

Values are Mean (SD) *, p < 0 05 Compared with atracurium control (AC) group #, p < 0 01 Compared with vecuronium control (VC) group

Conclusions: It is concluded that renal function is influenced action duration of atracurium and vecuronium. In renal failure there were no differences in action duration between the both relaxants

A.424 Pharmacokinetic interaction between propofol and alfentanil in healthy male volunteers

M.J Mertens, J. Vuyk, E. Olofsen, W. Olieman, A.G.L Burm, J G Bovill *Dept. of Anaesthesiology, Leiden University Medical Centre, Leiden, The Netherlands*

Background & Goal of the Study: Although the pharmacodynamic interaction between propofol (PROP) and alfentanil (ALF) has been described in detail, very little is known on whether PROP affects the pharmacokinetics of ALF We studied the effect of a semi-steady-state concentration of PROP on the pharmacokinetics of ALF.

Materials and Methods: With ethics committee approval and informed consent the pharmacokinetics of ALF were studied during 2 sessions in 8 healthy male volunteers in the presence and absence of PROP in a randomized, cross-over manner. While breathing 30% O_2 in air, ALF 12.5 μg/kg, iv, was given in 2 min, followed by 25 μg/kg/h for 58 min (session A) During session B, a target-controlled infusion of PROP, (target-concentration 1.5 μg/ml) was started 15 min before the start and maintained until 6 h after termination of the ALF infusion The interval between sessions was 3 weeks. The ECG, BP, RR, $ET\text{-}CO_2$, noninvasive CO and SaO_2 were monitored. The $ET\text{-}CO_2$ was maintained at 4 0–4.5 kPa Venous blood samples for plasma ALF and blood PROP determination were taken frequently during and until 6 h after termination

The pharmacokinetic parameters of ALF and the haemodynamic data in the presence and absence of propofol

	Session A	Session B	Difference (%)	P-value
V_1 (ml/kg)	191 ± 95	76 ± 23	−60	0 01*
V_{ss} (ml/kg)	393 ± 81	347 ± 42	−9	0 18
CL (mg/kg/min)	4 8 ± 1 5	3 9 ± 1 0	−19	0 07
CL_d (mg/kg/min)	9 4 ± 5 9	22 3 ± 24 9	137	0 19
$t_{1/2}$ alpha (min)	7 9 ± 4 8	2 2 ± 0 8	−72	0 01*
$t_{1/2}$ beta (min)	70 ± 9	74 ± 14	6	0 3
lag time (sec)	109 ± 14	38 ± 40	−65	0 0002*
CI (l/m^2)	3 28 ± 0 37	3 13 ± 0 38	−5	0 28
MAP (mmHg)	81 ± 6	69 ± 5	−15	<0 001*
SVR ($dynes/sec/m^{-5}$)	1006 ± 107	908 ± 109	−10	0 05*

of the ALF infusion The pharmacokinetics of ALF were determined using WINNONLIN and compared between sessions A and B with the paired t-test

Results and Discussion (see Table)· The mean (± SD) age and weight of the volunteers were 24 ± 3 yr and 74 ± 6 kg. The data were best fitted with a 2-compartment pharmacokinetic model. A lag time was included in the model because of venous sampling

Conclusion: Propofol affects the pharmacokinetics of alfentanil, in particular the initial distribution This may be explained by the haemodynamic changes induced by PROP in session B

A.425 Cerebrospinal fluid concentration of propofol during anaesthesia in man

M Abrahams[1], O Engdahl[1], A. Björnsson[1], M. Vegfors[1], B. Norlander[2], J. Ahlner[2], C. Eintrel[1] *Department of Anaesthesiology and Intensive Care[1] and Department of Clinical Pharmacology[2], University Hospital, Linköping, Sweden*

Background: The concentration of propofol in and surrounding the brain during propofol anaesthesia is unknown. Knowledge of this concentration is crucial for delineating the mode and specificity of action of propofol at molecular and cellular levels Previous *in vitro* studies investigating the intracellular effects of propofol and its action on the $GABA_A$ receptor have used propofol concentrations of 3 µg/ml to mimic clinical anaesthesia (1)

Materials and Methods: We simultaneously measured the concentration of propofol in cerebrospinal fluid (CSF) from an indwelling intraventricular catheter and the concentration in arterial blood in 5 neurosurgical patients before, during induction (at 2.5 and 5 minutes) and during a maintenance propofol infusion (at 15 and 30 minutes) After an induction dose of 2 mg/kg bw given over 2 minutes, anaesthesia was maintained with an infusion of 8 $mg.kg^{-1}\ h^{-1}$ for 15 minutes and then reduced to 6 $mg.kg^{-1}\ h^{-1}$. The propofol concentration in CSF and plasma was determined by high-performance liquid chromatography with fluorescence detection (2)

Results: The concentration of propofol in blood showed a predictable course and reached a pseudo-steady-state concentration of 10–20 µmol/L (1.5–3.0 µg/ml) after 5 minutes. The CSF concentration of propofol increased 2 5 minutes after induction and a plateau concentration of 0.2–0.3 µmol/L (30–50 ng/ml) was observed 15 minutes after induction.

Conclusion: The CSF concentration of propofol we demonstrated is less than 10% of the plasma concentration and is consistent with the high protein binding of the drug in plasma (3). If the propofol concentration measured in the CSF is equivalent to the free concentration in brain interstitium it suggests that the much higher concentrations used to investigate the actions of propofol on neurons *in vitro* may not be relevant to the clinical setting.

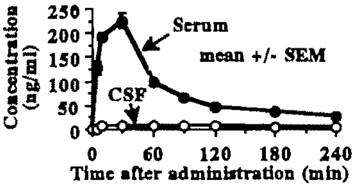
A.426 Midazolam concentrations in serum and cerebrospinal fluid after epidural administration in dogs

Tomoki Nishiyama, Kazuo Hanaoka. *Department of Anesthesiology, The University of Tokyo, Tokyo, Japan*

Background and Goal of Study: Epidural administration of midazolam has analgesic effects on postoperative somatic pain[1]. However, high dose midazolam induces sedation, amnesia and some muscle weakness. These effects by central nervous system (CNS) might be due to midazolam come through systemic circulation or cerebrospinal fluid (CSF). The purpose of this study was to elucidate by which way midazolam goes up to CNS in measuring midazolam concentrations in serum and CSF after epidural administration.

Materials and Methods: After the approval by our institutional review board, five mongrel dogs (8 to 12 kg) were anesthetized with intramuscular ketamine 20 mg/kg, then intravenous thiopental 5 mg/kg. Anesthesia was maintained with isoflurane 2% in oxygen (40%)–air mixture after tracheal intubation with vecuronium 0.5 mg/kg. Femoral artery was cannulated for blood pressure and pulse rate (heart rate) measurements and blood collection. Dorsal L3-4 region was clipped, 3 cm midline skin incision was made, muscles were gently dissected from the vertebrae, and 20 G epidural catheter was inserted using a loss of resistance technique like clinical procedure. Atlanto-occipital region was also clipped, 3 cm skin was incised, muscles were dissected, and 19 G catheter was inserted into intrathecal space to collect CSF Midazolam 1 mg/kg was injected epidurally Blood and CSF were drawn before, 5, 10, 30, 60, 90, 120, 180 and 240 minutes for the measurement of midazolam concentration. The measurement was done by gas chromatography (Teijin Bio Lab. Tokyo, Japan). Statistical analysis was performed with repeated measures analysis of variance followed by Fisher's protected least significant difference. $P < 0.05$ was considered to be significant

Results and Discussion: Blood pressure decreased and heart rate increased significantly 5 and 10 minutes and then went back to the control levels Serum concentrations of midazolam were significantly higher than CSF concentrations (Figure) Central effects of epidural midazolam was suggested to come through systemic circulation not by going up through CSF



Conclusions: Serum concentration of midazolam was significantly higher than CSF concentration after epidural administration It suggests the central effects of epidural midazolam come through systemic circulation

A.427 Serum concentrations of the enantiomers of tramadol during patient-controlled analgesia

Stefan Grond[1], Thomas Meuser[1], Heinz Uragg[2], Hans J. Stahlberg[2], Klaus A Lehmann[1] *[1]Department of Anaesthesiology, University of Cologne, 50924 Cologne; [2]Grunenthal GmbH, 52220 Stolberg, Germany*

Background & Goal of Study: Tramadol, a centrally acting analgesic, is used as a racemate containing 50% of a (+)- and 50% of a (−)-enantiomer. 98 patients recovering from major gynaecological surgery were treated in a randomised, double-blind study with (+)- tramadol, (−)-tramadol or the racemate [1]. Following an i.v. bolus up to a maximum of 200 mg, patient-controlled analgesia with demand doses of 20 mg was made available for 24 hours. The clinical results showed that (+)-T and racemate were more potent analgesics than (−)-T, whereas the incidence of adverse events was higher in (+)-T patients than in racemate patients This abstract presents the pharmacokinetic results in 92 patients.

Materials & Methods: Prior to each demand, the serum concentrations of the enantiomers of tramadol and its metabolite M1 were measured The concentrations of (+)-T and (−)-T were determined by a modified gas chromatographic-mass spectrometric method on a column coated with CP-Cyclodextrin-β-2,3,6-m-19; the (+)-M1 and (−)-M1 concentrations were determined after derivatisation with diazoethane by gas chromatography on the same above mentioned column and with a nitrogen-selective (NDP) detector. Analysis of variance including Scheffe's test for pair-wise comparison was used to compare the concentrations between the 3 treatment groups (SPSS, $p < 0.05$)

Results & Discussion: The mean concentrations of (−)-T and (−)-M1 in the (−)-T group were higher than those of the sum of (+)- and (−)-T and of (+)-M1 and (−)-M1 in the racemate group, which in turn were greater than those of (+)-T and (+)-M1 in the (+)-T group ($p < 0\ 05$)

Therapeutic serum concentrations of tramadol and the metabolite M1 in the 3 treatment groups

Treatment group	Analysed substance	Patients n	ng/ml mean ± SD
(+)-T	(+)-T	32	470 ± 323
racemate	T_{sum}	28	590 ± 410
(−)-T	(−)-T	32	771 ± 451[a]
(+)-T	(+)-M1	27	57 ± 18
racemate	$M1_{sum}$	22	84 ± 34[b]
(−)-T	(−)-M1	32	96 ± 41[b]

T_{sum} = (+)-T + (−)-T, $M1_{sum}$ (+)-M1 + (−)-M1 [a] difference to (+)-T statistically significant; [b] difference to (+)-M1 statistically significant

Conclusion: The presented pharmacokinetic results are in agreement with the clinical findings that the racemate is superior to either enantiomer alone.

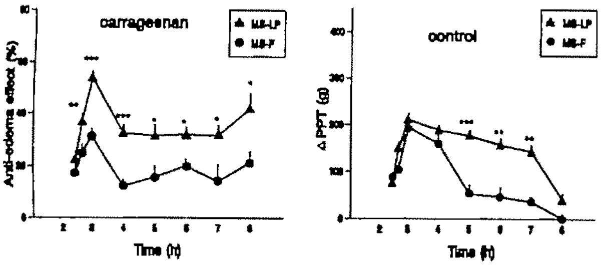
A.428 Antinociceptive/anti-oedema effects of free and liposomal morphine in a rat model of carrageenan-induced arthritis

M M Puig[1], O. Pol[1], S. Sánchez, L Rodríguez, M.E. Planas. [1]*Dept of Anaesthesiology, Hospital del Mar, IMIM and Dept of Pharmacology, UB, Facultad de Odontología, Barcelona, Spain*

Background: Liposomes are used to slow active-drug delivery and decrease toxicity. In animals, liposomal morphine (MS-LP) has a more sustained analgesic effect and decreased toxicity. Acute inflammation sensitizes opiate receptors and enhances the peripheral effects of opiates (1). Our hypotheses was that during inflammation, MS-LP would maintain the enhanced antinociceptive effects manifested by free morphine (MS-F), while showing a longer duration of action.

Methods: we evaluated the antinociceptive and anti-edema effects of s c MS-F and MS-LP, in a rat model of carrageenan induced inflammation. Antinociception was evaluated by paw pressure threshold (PPT) and edema, by measuring the volume of the paw

Results: the antinociceptive effects of MS-F were increased 2 6 times during inflammation, while that of MS-LP was unaltered MS-LP was twice as potent as MS-F in non injected animals. For the anti-edema effects, MS-LP produced a more prominent ($P < 0\ 01$) and prolonged effect ($P < 0\ 05$) than MS-F. In carrageenan treated animals, MS-F had a higher peak for PPT but duration was prolonged by encapsulation ($P < 0\ 01$) In non inflamed (control) animals, MS-LP had a longer duration and the area under curve increased 40%. The effects of MS-F were completely reversed by naloxone, while those of MS-LP were partially antagonized



Discussion: inflammation enhances the antinociceptive effects of free but not liposomal morphine, while encapsulation increases the duration of action. The anti-edema effects are more pronounced and sustained after encapsulation. We concluded that MS-LP manifests a better anti-edema effect with a more prolonged antinociceptive action

A.429 Experimental *In vitro* release studies of morphine liposomal association

M. Alafandy, C Robert, V. Maes, F. Legros, F. Camu. *Department of Anesthesiology, Flemish Free University of Brussels, Laarbeeklaan 101, 1090 Brussels, Belgium*

Background: Most trials concerning the entrapment of morphine used high concentrations and amounts of the opioid (1) or large multivesicular liposomes (2). This leads to the administration of supraclinical doses entrapped in the liposomal aqueous phase. We studied the association and release of this amphophilic compound (pKa 7.9) inserted into the phospholipid bilayers at concentrations relevant for clinical practice.

Materials and Methods: Liposomal morphine (lipo-MP) formulations were prepared from lipid films of egg phosphatidylcholine (EPC)/cholesterol/α-tocopherol (molar ratio 4 3 0 07) and quantities of apolar morphine (MP) 2, 5 and 10 mg so that the EPC/MP mole ratio range was 26 1, 10.1 and 5.1 ($n = 3$) The morphine-liposome association efficiency increased from 85% to 95% and around 100% respectively The multilamellar vesicles (MLVs) obtained were examined by light microscopy and extraliposomal crystals were seen in the preparations from 10.1 and 5.1 mole ratio. One milliliter of the preparations was put in a dialysis bag immersed in 150 ml PBS (closed system) at the physiological pH 7 4 at 37°C Unencapsulated MP at a concentration of 5 mg/ml was used as control. Alternatively, the medium was continuously renewed at a 23 ml/h rate (open system). Serial samples were analysed by HPLC at different times

Results: In the closed system, the release of liposomal MP was controlled by a concentration gradient and reached a plateau after 24 h. while this was achieved after 3 h. with unencapsulated MP In the open system, the clearance of liposomal MP was biphasic and lasted for more than 3 days being dramatically slower than the one of native MP (Table 1).

In vitro-release of liposome-MP (open system), mean ± DS ($n = 3$)

Lipo-MP, mg/ml	Cmax, μg/ml (3–6 h)	C12 h, μg/ml	C24 h, μg/ml	C48 h, μg/ml	C72 h, μg/ml
2	15 8 ± 1 2	6 4 ± 2 4	1 3 ± 0 4	0 05 ± 0 02	0 01 ± 0 01
5	21 9 ± 5 4	13 2 ± 2 4	4 5 ± 1 3	0 4 ± 0 2	0 02 ± 0 01
10	32 1 ± 1 2	21 5 ± 1 1	14 0 ± 2 1	3 5 ± 0 4	0 60 ± 0 5
Native MP (10)	65 3	0 9	0 3		

Conclusions: The experimental data suggested the release of MP from phospholipid bilayers is more sustained as the liposomal MP load is increasing The association-release *in vitro* assays are a reliable method to foresee the *in vivo* behaviour of a liposomal encapsulated drug

A.430 Effects of melatonin by intrathecal injection. An experimental study in the rat

M Bahar, M. Chanimov, M.L Cohen, I Korfman, Y. Grinspoon *Assaf Harofe Medical Center, Zerifin, Israel*

Background: Melatonin has been shown to have significant role in the biologic regulation of circadian rhythms, sleep and mood In mans, large doses of melatonin, administrated orally, have a marked short term hypnotic effect. In the light of what is already known about melatonin physiology, we sought to examine the possible therapeutic application of melatonin in anesthesia assessing the hypnotic and antinociceptive effects of a bolus of melatonin, alone or combined with fentanyl, injected intrathecally (IT) or IV in a rat model, and to compare these effects with those produced by fentanyl alone or lidocaine.

Methods: 72 male, Wistar-strain rats, (250–300 gr) divided into 6 groups. in each group of 12 animals, 6 (sub-group A) were studied for the neurological and antinociceptive effects resulting from the substance injected, while breathing room air The remaining 6 (sub-group B) were examined for the possible haemodynamic effects of the substance injected while inhaling 0 6% halothane in oxygen, which sedated them sufficiently to enable haemodynamic monitoring

Injection procedures: (1) 0 08 mg/kg Melatonin (0 02 ml, 0.1%) were injected IT.

(2) IT injection 0 04 mg/kg melatonin (0.01 ml) and of 0.04 mg/kg fentanyl (0 01 ml).

(3) IV injection of 0 08 mg/kg melatonin (0 02 ml, 0 1%)

(4) IT injection of 0.02 ml lidocaine 2% (3 33 mg/kg)

(5) IT injection of 0 08 mg/kg fentanyl (0 005%, 0 02 ml)

(6) 0.6% halothane in 02 but received no IT or IV injection.

Results: Lumbar intrathecal injection of melatonin, 0 08 mg/kg, produced profound sedation and minimal antinocieceptive effect over the lower trunk and hind-limbs of the animals The addition of fentanyl resulted with a greater antinocelceptive effect. IV injection of the same dose of melatonin produced mild sedation.

Melatonin, IT or IV caused a slight reduction in the respiratory rate, with no significant changes in arterial blood gases. A mild decrease in heart rate and systolic blood pressure was also noticed

Conclusions: The clinical applications of these finding will be discussed in details

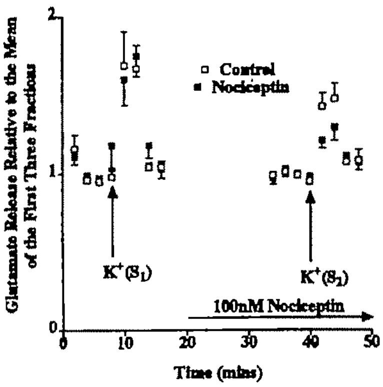
A.431 Nociceptin inhibits K⁺-evoked glutamate release from rat brainstem slices

B. Nicol[1], D.G. Lambert[1], D J Rowbotham[1], D. Smart[2], A.T McKnight[2]
[1]*University Department of Anaesthesia, Leicester Royal Infirmary, Leicester LE1 5WW,* [2]*Parke-Davis Neuroscience Research Centre, Robinson Way, Cambridge CB2 2QB, UK*

Background & Goal of Study: The orphan opioid receptor, ORL-1 is expressed in the brainstem [1] Nociceptin or orphanin FQ the endogenous ligand for ORL-1 is reported to produce hyperalgesia, analgesia and anti-opioid effects [2]. In an attempt to understand these ions we have examined the effects of nociceptin on K^+-evoked glutamate release from rat brainstem

Materials & Methods: Slices were prepared from Wistar rats and suspended in oxygenated bicarbonate buffer 0 75 ml of gravity packed slices were perfused as described [3] 2 × 2 min pulses of 46 mM K^+ were applied to the slices 30 min apart, S_1 and S_2 respectively 100 nM nociceptin was applied 10 min after S_1 until the end of the experiment. 30 μM amastatin, bestatin, captopril and phosphoramidon and 0.1% BSA were added 10 min after in control and nociceptin treated slices to prevent nociceptin breakdown. Perfusate glutamate concentrations are determined fluorimetrically [3] Data are mean ± sem, S_2/S_1 ratios were calculated from the areas under the S_1 and S_2 curves and analysed by Wilcoxon rank sum test

Results & Discussion: 46 mM K+ depolarisation produced monophasic releases of glutamate during S_1 and S_2, with a an S_2/S_1 ratio for control slices of 1.18 ± 0.11 (n = 7) Nociceptin reduced S_2, thus reducing the S_2/S_1 ratio to 0.71 ± 0.06, an inhibition of ~36%, $p < 0.05$ (Fig 1).



Conclusions: Nociceptin may modulate pain via a reduction in brainstem glutamatergic transmission

A.432 Prilocaine and lidocaine inhibit (^{3}H)-noradrenaline uptake into 293-hNET cells

P.I. Joyce, R. Atcheson, D.J Rowbotham, R.D. Blakely[1], D.G. Lambert. *University Department of Anaesthesia, Leicester Royal Infirmary, Leicester, LE1 5WW. (Fax 0116 2854487), UK; [1]Vanderbilt University School of Medicine & Center for Molecular Neuroscience, Nashville, TN 37232-6600, USA*

Background & Goal of Study: Intravenous regional guanethidine Bier's block provides a chemical sympathectomy desirable for the relief of reflex sympathetic dystrophy [1]. Local anaesthetic (usually prilocaine or lignocaine) is co-administered to reduce the discomfort caused by noradrenaline displacement We have previously demonstrated that a range of local anaesthetics at clinically achievable concentrations inhibit the uptake of tritiated noradrenaline ([^{3}H]-NA) in SH-SY5Y human neuroblastoma cells and hence would be expected to inhibit the uptake of guanethidine[2, 3]. In this study we have examined the effects of prilocaine and lignocaine on [^{3}H]-NA uptake in cells stably expressing the recombinant uptake$_1$ transporter (293-hNET).

Materials & Methods: 293-hNET cells were maintained in high glucose (4500 mg/l) Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% foetal calf serum, 100 IU/ml penicillin, 100 μg/ml streptomycin, 2 mM L-glutamine and 250 μg/ml geneticin (G418) at 37°C in 5%CO_2/humidified air. Stock cultures were passaged weekly, refed twice weekly and 24 hours prior to any experimental procedure 293-hNET cell suspensions (100–200 μg protein/ml) were preincubated in 0.5 ml volumes of Krebs-HEPES buffer at pH7.4 for >30 mins and <120 mins in the presence or absence of prilocaine and lignocaine (3 μM–100 mM), [^{3}H]-NA (~25 nM) was added and the reaction continued for a further 4 mins. Reactions were terminated by rapid vacuum filtration using a millipore harvester Non-specific uptake was defined in the presence of 10 μM imipramine. The pIC_{50} of prilocaine and lignocaine were estimated by non-linear regression using GRAPHPAD PRISM2. All data are mean ± s.e. mean.

Results & Discussion: 293-hNET cells take up [^{3}H]-NA in a time dependent manner reaching a maximum at 10 minutes. Prilocaine and lignocaine dose dependently inhibited [^{3}H]-NA uptake into 293-hNET cells with pIC_{50} of 3.19 ± 0.05 (644 μM, n = 7) and 2.79 ± 0.11 (1.64 mM, n = 4) respectively. This compares with values of 3.72 ± 0 07 (189 μM, n = 8) and 2.96 ± 0.013 (1.1 mM, n = 4) respectively for SH-SY5Y cells endogenously expressing the uptake$_1$ transporter. [3]

Conclusions: These data with the recombinant uptake$_1$ confirm findings from our previous study with the endogenous NA transporter.

A.433 Naltrindole-5′-isothiocyanate selectively reverses sufentanil induced respiratory depression in rats

C. Verborgh[1], J. D'Haese[1], T.F. Meert[2]. [1]*Departement Anesthesie, Akademisch Ziekenhuis VUB, B-1090, Brussels;* [2]*Departement Neuropsychopharmacologie, Janssen Research Foundation, B-2340, Beerse, Belgium*

Background & Goal of Study: Although the cross-interactions between the μ- and the δ-opiate receptor subtypes with regard to supraspinal analgesia are well documented, only a few papers describe the role of the δ-opiate system on μ-opiate induced respiratory depression (1, 2) In order to clarify the functional interactions between both opiate receptor subtypes with regard to antinociception and respiratory depression, rats were intravenously injected with the μ-opiate agonist sufentanil and subsequently intravenously challenged with the delta antagonist naltrindole (NTI) or naltrindole 5′-isothiocyanate (5′-NTII), a δ-2 antagonist

Material & Methods: Approval from the Institutional Animal Care and Use Committee was obtained. Naive male Wistar rats weighing 215–310 g were anaesthetised with etomidate for insertion of an arterial cannulla. After emergence from anaesthesia, the rats were installed in Bolman-cages. The rats were intravenously injected with 2 50 μg/kg of the μ-opiate agonist sufentanil (n = 66) or vehicle (n = 10). Five min after the opioid they were intravenously injected with NTI at 0 16, 0.63, 2 5 and 10 mg/kg or 5′-NTII at 0 16, 0.63, 2.5 and 10 mg/kg. Antinociception was measured by means of the tail flick latency and respiratory depression was evaluated by means of blood gas analysis of PaCO2, PaO2 and oxygen saturation. Statistical analysis included one-way ANOVA, MWU- and Wilcoxon-test.

Results & Discussion: NTI, but not 5′-NTII, antagonized the sufentanil-induced antinociception at doses ≥ 0.63 mg/kg NTI The sufentanil-induced hypercapnia and hypoxia were diminished with 10 00 mg/kg of both NTI and 5′-NTII. Also at 2.50 mg/kg of both antagonists, a short lasting reduction of the respiratory depression was present. These data indicate that 10 mg/kg NTI antagonizes the sufentanil-induced antinociception and respiratory depression in rats, while 10 mg/kg 5′-NTII only reverses the respiratory effects.

Conclusion: With 10 mg/kg 5′-NTII, a dissociation could be obtained between the intravenously sufentanil-induced antinociception and respiratory depression in rats, implying different regulatory mechanisms of the δ-receptor subtypes on the μ-opiate agonist-induced effects.

A.434 Onset of relaxation after an intubating dose of rocuronium is not accelerated by priming

J C. De Mey, D. Pattyn, E. Mortier, G. Rolly. *Department for Anaesthesia, University Hospital Gent, Belgium*

Aim: We wanted to evaluate whether priming with rocuronium (R), atracurium (A) or vecuronium (V) accelerated the onset of relaxation after an intubating dose of R. Other relaxants than R as the priming agent were also studied because only R has an early and important presynaptic effect (1)

Method: Four groups of 20 informed and consenting patients each were studied. Anaesthesia was induced and maintained IV with propofol and sufentanil Neuromuscular function was evaluated with acceleromyography using 0.1 Hz stimulation. In a control group (C-R) an intubating dose of 0 6 mg/kg R was injected without priming. In the three other groups a priming dose of 10% of an intubating dose of either R, A or V (group R-R, A-R, V-R) was injected. After a priming interval of 3 minutes the remaining 90% of an intubating dose of R (0.54 mg/kg) was injected. Lag and onset time (the time from injection till achievement of respectively the first signs of relaxation and maximal or total relaxation) were registered.

Results: The median lag and onset times (in seconds) are shown in Table

Table

	C-R	R-R	A-R	V-R
Lag time	30	30	30	25
Onset time	130	200*	150	170

(* p < 0 05 in comparison with the control group)

The onset time was significantly longer in the rocuronium priming group.

Discussion: Priming with either R, A or V does not accelerate the onset of relaxation after an intubating dose with R. The slower onset in the R-R group could be attributed to the lower concentration gradient between plasma and effect site following a 10% lesser intubation dose Griffith et al. observed a significant faster onset time with a similar dosage, a 2 min priming interval and a stimulation frequency of 1 Hz (2) Because R has an early and important presynaptic effect the stimulation frequency of 1 Hz causes fading in the priming group and accelerates the onset. In our opinion priming studies with R must be performed with a stimulation mode which can not cause fading (maximum 0 1 Hz).

A.435 Influence of induction of anaesthesia on intubation conditions after rocuronium-induced neuromuscular block: comparison of thiopentone and ketamine

B. Hubert, P. Hans, J.F. Moineau, J F. Brichant, F. Damas, P Y Dewandre, M. Lamy. *University Department of Anesthesia & Intensive Care Medicine, CHR Citadelle, CHU Liège, Liège, Belgium*

Background and Goal of Study: Intubation conditions are known to be affected by the depth of anesthesia and the drugs used to provide anesthesia The present study was designed to assess the effect of thiopentone (T) and ketamine (K) on intubation conditions after rocuronium-induced neuromuscular block

Methods: After institutional approval, 22 consenting ASA I patients with clinically normal airways, aged 21–44 yr, and undergoing minor elective surgery under general anesthesia were studied Patients were premedicated with 1 mg alprazolam given orally 1 h before surgery and randomly allocated to one of two groups according to the induction of anesthesia. Group T received 2 mg midazolam and 5 mg kg^{-1} thiopentone. Group K received 2 mg midazolam and 2 5 mg kg^{-1} ketamine. Muscle relaxation was provided with rocuronium 0.6 mg kg^{-1}. Tracheal intubation was attempted by an anesthetist blinded as to the allocation, 60 s after rocuronium administration. Intubation conditions were graded as excellent (8–9), good (6–7), fair (3–5), and poor (0–2), on the basis of jaw relaxation, aspect of vocal cords, and response of the diaphragm which were scored from 0 to 3 Neuromuscular transmission was assessed as the response of the adductor pollicis to train-of-four supramaximal stimulation, using a TOF-Guard accelograph monitor. Intubation conditions were compared with the Fischer's exact test and the degree of neuromuscular block was analysed using the Mann-Whitney test $P < 0.05$ was considered statistically significant

Results and Discussion: Both groups were comparable in terms of age, weight and gender distribution. Tracheal intubation was performed within 10 s in all patients. The proportion of excellent intubation conditions was significantly higher in group K (8/11) than in group T (2/11); no significant difference was observed when excellent and good conditions were combined The degree of jaw relaxation did not differ between groups but conditions of vocal cords and diaphragmatic response were significantly better in group K than in group T. The degree of neuromuscular block assessed in both groups at the time of intubation did not differ significantly (T1 response: 46.1 ± 24.4% in group K versus 55 2 ± 22 6% in group T).

Conclusions: The results of the study showed that ketamine provided a significantly higher excellent score of intubation than thiopentone after administration of 0 6 mg kg^{-1} rocuronium This difference was associated with better conditions of vocal cords and diaphragmatic response but could not be ascribed to a deeper degree of neuromuscular block assessed at the adductor pollicis.

A.436 Rocuronium neuromuscular blockade at the masseter and adductor pollicis muscles in adults

L de Rossi, H. Fritz, N.-P. Preußler, U. Klein *Clinic for Anaesthesiology and Intensive Care Therapy Friedrich-Schiller-Universität, 07740 Jena, Germany*

Background & Goal of Study: Rocuronium has a faster onset time at the laryngeal muscles than at the adductor pollicis although the laryngeal muscles have a lower sensitivity to muscle relaxants. This is due to a more rapid equilibration between plasma concentration and that at the laryngeal muscles (1) In this context the rocuronium neuromuscular effect on muscles of the upper airway is an area of some interest. Thus, we evaluated onset and recovery characteristics of rocuronium at the masseter (MM) in comparison to the adductor pollicis muscle (AP).

Materials & Methods: After IRB approval and informed consent, 15 patients were studied. Anaesthesia was induced and maintained with propofol, fentanyl and oxygen/nitrous oxide Neuromuscular responses were monitored with accelerometry (TOF-Guard) Branches of the mandibular nerve were stimulated 1–2 cm anterior to the ear lobe under the zygomatic arch and near the mandibular notch. To measure onset time, supramaximal single twitch stimulation was evoked at 0.1 Hz and, after a stabilization period of 3 min., 0 6 mg/kg rocuronium was injected. Recovery was measured using TOF stimulation every 15 sec until TOF ratio reached 0.85. Statistical analysis were performed with Wilcoxon-test ($p < 0 05$).

Results & Discussion: Onset time was faster at the MM than at the AP Recovery started earlier and time to 25% T_1 recovery was shorter at the AP. No differences were found for times to 50% and 75% T_1 recovery, and for TOF ratio 0.85 (Table 1)

Table 1

	Onset (sec)	Recovery (min)				
		T_{first}	25%	50%	75%	TOF 0.85
AP	93 ± 25	25 ± 5	30 ± 5	35 ± 6	39 ± 7	51 ± 11
MM	48 ± 11	29 ± 6	34 ± 8	38 ± 10	43 ± 11	48 ± 13
p	<0.001	$p < 0 05$	$p < 0 05$	NS	NS	NS

Values are mean ± SD, NS = not significant

Conclusion: We conclude that the rapid rocuronium onset time is a result of the high sensitivity of the MM to muscle relaxants, and the rapid equilibration between plasma and masseter muscle rocuronium concentration Further, we suggest that this higher sensitivity also contributes to a slower initial recovery (2).

A.437 Evaluation of intense rocuronium neuromuscular block using the post-tetanic counts principle

M Ibsen, P. Schultz, D. Østergaard, L T. Skovgaard. *Department of Anaesthesiology, Gentofte Hospital and Statistical Research Unit, University of Copenhagen, DK-2900 Hellerup, Denmark*

Background and Goal of Study: During profound neuromuscular block no response to TOF nervestimulation is seen The post tetanic count (PTC) principle can be used to quantitate the intensity of the block by counting the number of responses following a tetanic stimulation (1). The purpose of this study was to evaluate the relationship between the number of PTC and time to return of the first response to TOF nervestimulation following 3 different doses of rocuronium.

Materials and Methods: After Ethics committee approval and informed consent, 85 patients were included in the study. Anaesthesia was induced with fentanyl followed by thiopentone The patients were randomly given rocuronium 0.6, 0.9 or 1.2 mg/kg. Tracheal intubation was performed at 60 s by a blinded investigator. Intubation conditions were graded using a scoring scheme (2). The neuromuscular block was monitored using TOF stimulation every 12 s and a Myograph 2000. At 6 min intervals, tetanic stimulation (50 Hz) was applied for 5 s preceded and followed by a 30 s period of 1 Hz stimulation until the reappearance of the first response in the TOF nerve stimulation.

Results and Discussion: The intubation conditions were graded as excellent or good in all patients. The first response to TOF was seen 21.6 (5.2), 33 6 (7 3) and 48.7 (13 6) (mean (SD)) min following 0 6, 0.9 and 1.2

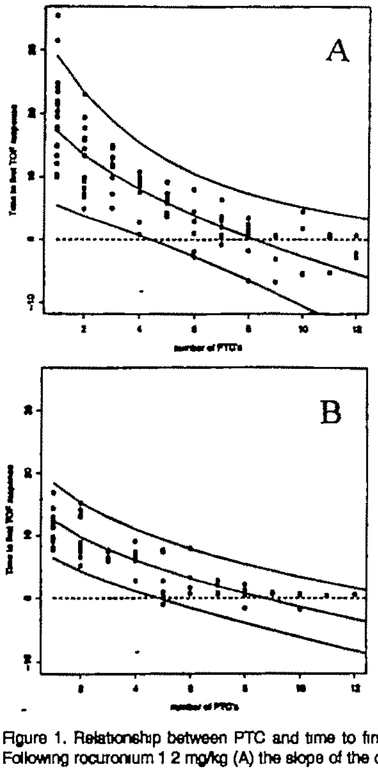

Figure 1. Relationship between PTC and time to first response to TOF stimulation Following rocuronium 1 2 mg/kg (A) the slope of the curve differed from that following 0 6 and 0 9 mg/kg (B)

mg/kg of rocuronium, respectively. A close relationship was found between the time to first response to TOF and the PTC

Conclusion: The PTC principle can be used to predict the time to first response to TOF stimulation during profound rocuronium induced neuromuscular block.

A.438 Antagonism of rocuronium block in the presence of isoflurane

K.C. McCourt, R.K. Mirakhur, R.N. Kumar *Department of Anaesthetics, The Queen's University of Belfast, Belfast BT9 7BL, N, Ireland*

Background: Antagonism of neuromuscular block may be impaired in the presence of volatile anaesthetics [1]. We have previously shown that under isoflurane anaesthesia, recovery from rocuronium block is similar when neostigmine 35 or 50 μg kg^{-1} is administered at 10% or 25% recovery [2]. In this study we compared recovery times following neostigmine administration when isoflurane administration was discontinued.

Methods: Forty patients, with their informed consent and Ethics Committee approval, were anaesthetised with thiopentone 4–6 mg kg^{-1}, fentanyl 2 μg kg^{-1} and 67% N_2O in O_2 and isoflurane. After stabilisation of control train-of-four (TOF) responses using mechanomyography, rocuronium 0 5 mg kg^{-1} was given followed by further boluses as required. Isoflurane was discontinued at the end of the procedure and 10 patients each allocated randomly to receive neostigmine 35 (Groups I and II) or 50 μg kg^{-1} (Groups III and IV) at 10 or 25% recovery of T_1 The recovery times of T_1 to 90%, of TOF ratio to 0.8, and the T_1 25–75% were recorded. The data were compared with 40 subjects from the previous study [2] where isoflurane was continued (Groups Ia, IIa, IIIa, IVa). The results were subjected to ANOVA.

Results and Discussion: There was no significant difference in the times to recovery of T_1 to 90% or of the TOF ratio to 0.8, or the interval T_1 25–75% among the groups (Table 1). Our results may indicate that the time during which recovery occurred was not enough for the washout of isoflurane to influence the results. In conclusion, our results indicate that discontinuing isoflurane at the time of administration of neostigmine did not shorten recovery times of rocuronium

Recovery times (min) (n = 10 except a = 9 and b = 8, mean (SD)).

Group	T_1 90%	T_1 25–75%	TOF 0 8
I	5 9 (1 2)	3.1 (1.0)	10 3 (4 3)^a

A.439 Pharmacokinetic and pharmacodynamic model of rocuronium in patients undergoing liver transplantation

J A. Alvarez-Gomez, M.E. Morales, F. Acosta, M M Martinez, M.E. Estelles, J Fabregat, M.A. Rodaguez, T. Sansano, P. Parrilla, A.J. Brugger. *Pharmacology and Surgery Departments, University of Murcia, Anesthesiology Departments: Hospital Arrixaca Murcia and Hospital Rosell, Cartagena, Spain*

The aim of this study is to compare the PK/PD of Rocuronium in healthy adults, normal hepatic function (control group n = 7 (CG)) and in patients with end-stage liver disease, Child's B-C class, (liver transplantation group n = 7 (LT)).

Patients and Methods: Anaesthesia was induced with midazolam, thiopental, fentanyl and maintained with O_2/Air/midazolam and fentanyl as needed. Rocuronium bolus 0.6 mg/kg, Intubation at 60 s, followed continuous infusion was used to obtain blockade level >90%, (start rate 0.5 mg/kg/h). 1 -PD STUDY. the ulnar nerve was stimulated at the wrist with supramaximal TOF and single stimuli, the resultant thumb acceleration measured and recorded on card (TOF-GUARD^R). Lag, latent and onset time and number of changes and mean infusion rate were obtained. 2.-PK STUDY: Plasma (prior to and 1–3–5–10–15–30–60–120–180–240–300 and stop infusion-1–5–10–15–30 min post end infusion), urine (up to 24 h), ascytis and blood losses samples were obtained in each patient. Rocuronium concentration in samples were analysed by HPLC (1). Individual concentration vs effect-time data were fitted to a two exponential equation by means of WIN NONLIN and PKPDFIT programs (2–3). Vss, C1, MRT, t1/2$_\chi$, ke$_0$, t1/2 ke$_0$, γ, EC_{50} and other PK parameters were estimated.

t 1/2 ke$_0$ (min)	3 47 (2 03)	6 32 (2.11)
γ	3 69 (1 2)	2 88 (2 27)
EC50 (ng/ml)	766 (323)	1054 (339)

Data as mean (SD) * $p < 0.05$ ** $p < 0\ 01$

Conclusions: In LT patients, rocuronium exert a slightly prolonged effect with a similar onset time (with a large variation) as shown by the NS differences in clinical and PK/PD variables, except latent time The differences in Cl, Vss, t1/2 β and MRT suggest that rocuronium will be present at an effective concentration for a longer period in LT patients The similar rate constant to transfer rocuronium to effect compartment, suggest that the variation in onset is only caused by the increased Vss in LT group. The PK/PD model parameters shown that LT patients need the same plasma concentration to obtain a comparable degree of muscle relaxation as normal patients

A.440 Chronic carbamazepine therapy and the duration of neuromuscular blockade by rocuronium

A. Spacek, F.X. Neiger, C.-G. Krenn, K. Horauf, C K Spiss, H.G. Kress *Department of Anesthesia and General Intensive Care (B), University of Vienna, Währinger Gürtel 18-20, A-1090 Vienna, Austria*

Background and Goal of Study: Patients chronically receiving carbamazepine are known to be resistant to certain, but not all nondepolarizing muscle relaxants (1, 2). Therefore, the influence of carbamazepine on rocuronium-induced NB was investigated in this study.

Materials and Methods: After IRB approval and informed consent, until now a total of 16 patients with ASA physical scores I–III scheduled for neurosurgical procedures were included in the study Only group I (n = 8) patients had received carbamazepine for at least 4 weeks. After induction of anesthesia with thiopental and fentanyl, rocuronium (0.6 mg/kg) was given. Anesthesia was maintained by moderate hyperventilation (Et CO2 at 30–35 mmHg) with N2O 70% and isoflurane 0.5% in O2 Skin temperature was maintained above 36°C. The ulnar nerve was stimulated at the wrist with train-of-four stimuli. Using a Datex NMT monitor, lag time, onset, 10%, 25%, 50%. 75% recovery and the recovery index (RI: 25–75%) were determined. The two tailed t-test for unpaired data and ANOVA was used for statistical analysis $P < 0.05$ was considered statistically significant.

Results and Discussion: Demographic data and measured parameters did not statistically differ between both groups (Table: Mean ± SD in min).

	Carbamazepine	Control	p
Lag time	0 8 ± 0 2	0 9 ± 0 3	NS
Onset	2 4 ± 1 3	2.7 ± 1 0	NS
10% Recovery	19 0 ± 7 6	26 6 ± 10 8	NS
25% Recovery	25 33 ± 8 4	33 5 ± 10 1	NS
50% Recovery	30 3 ± 9.2	40 2 ± 11.8	NS
75% Recovery	36.4 ± 11 4	51.3 ± 15 4	NS
Recovery Index	11 0 ± 4.6	17 8 ± 6.0	NS

Conclusion: Our preliminary results demonstrate that patients on chronic carbamazepine therapy show a shorter duration of rocuronium-induced NB. However, this tendency did not reach statistical significance at this stage of the still ongoing open study. This observation is of special interest as a significant decrease in duration of rocuronium-induced NB was reported in one patient on chronic phenytoin therapy (3). An increased hepatic clearance of the drug seems to be a likely mechanism of this effect.

A.441 Onset, intubating conditions and duration after mivacurium, rocuronium and their combination in young and elderly adults

C. Motamed, F Donati. *Hôtel-Dieu de Montréal-Université de Montréal, Montréal, Québéc, Canada*

Background: The combination of mivacurium and rocuronium is more potent than each drug given alone, with a fast onset and a short duration of action[1] However, intubating conditions has not been reported with this combination This study was designed to measure neuromuscular block and intubating conditions (INT) of mivacurium, rocuronium, and a combination of both drugs in young and elderly adults.

Methods: After informed consent, two groups of 45 patients scheduled for elective surgery under general anesthesia requiring tracheal intubation were enrolled into the study. Patients aged 18–65 yr. were enrolled in group Young (Y), and those aged 66–90 were in group Elderly (E) Patients were randomized to receive mivacurium, 0.25 mg kg^{-1}, or mivacurium, 0.08 mg.kg^{-1} plus rocuronium, 0.2 mg.kg^{-1}, or rocuronium, 0.6 mg.kg^{-1} The trachea was intubated 2.5 min after the injection of the relaxant The response of the adductor pollicis was measured with accelerometry. The response of the orbicularis occuli (OO) was estimated visually Intubating conditions were rated by an observer blind to the study. No significant differences were found between the relaxants given with respect to onset at AP, onset at OO and (INT) For statistical analysis one way ANOVA and Kruskall-Wallis ANOVA was used as appropriate.

Results: Onset and intubating conditions were similar in the Y and in the E. In the Y group, recovery was longer in the rocuronium subgroup than in either the mivacurium or combination subgroups In the E group, recovery was shortest with mivacurium, intermediate with the combination and longest with rocuronium.

	Group Y (n = 45)		
	MIV (n = 14)	COM (n = 18)	ROC (n = 13)
Onset AP, sec (mean ± SD)	271 ± 103	276 ± 102	253 ± 132
Onset OO, sec (mean ± SD)	142 ± 54	151 ± 49	158 ± 67
Dur 25%, min (mean ± SD)	23 ± 6	25 ± 7	39 ± 11*
INT (1/2/34)	7/6/2/0	8/7/0/0	10/5/0/0

	Group E (n = 45)		
	MIV (n = 15)	COM (n = 15)	ROC (n = 15)
Onset AP, sec (mean ± SD)	239 ± 115	276 ± 102	253 ± 132
Onset OO, sec (mean ± SD)	158 ± 75	173 ± 62	184 ± 110
Dur 25%, min (mean ± SD)	24 ± 6	35 ± 11*	54 ± 11*
INT (1/2/34)	11/4/0/0	11/4/0/0	13/2/0/0

*P < 0.05

Conclusions: This study suggests that, in adults of all ages the combination of rocuronium and mivacurium yields onset times and intubation conditions at 2.5 min similar to those obtained with either drug used alone, but by using only 2/3 as much total drug. Thus, mivacurium-rocuronium combination can be used in short procedures as an alternative to mivacurium

A.442 Pharmacodynamics and tryptase release of rocuronium and cis-atracurium in anaesthetised patients

J.J Anño, J M Velasco, L. Sante, F. Lopez Timoneda. *Servicio de Anestesiología, Reanimación y Terapia del Dolor Hospital Clinico San Carlos, Madrid, Spain*

Background and Goal of the Study: Rocuronium (R) and Cis-atracurium (CA) are two non-depolarizing muscle relaxants with an intermediate duration of action (1, 2). The aim of this study was to compare the intubating conditions, pharmacodynamics and tryptase release after the administration of this two muscle relaxants.

Patients and Methods: Forty ASA I or II surgical patients were studied. Patients were randomized into two groups (group CA and group R) of 20 patients each Premedication consisted of droperidol (2.5–5 mg) and fentanyl (0.05–0.10 mg) IV before induction. Anaesthesia was induced using thiopental (5 mg/kg) and fentanyl (0.10–0.15 mg) Neuromuscular transmission was monitored using a TOF-Guard monitor (Biometer) The group CA received a bolus of 0.15 mg/kg and the group R a bolus of 0.6 mg/kg to facilitate tracheal intubation Intubating conditions were evaluated at 1 min (group R-1), 1.5 min (groups R-2 and CA-1) and 2 min (group CA-2). Intubating conditions were evaluated as excellent, good, fair or bad. Anaesthesia was maintained with nitrous oxide 65% in oxygen and fentanyl as required An infusion at a starting rate of 0.09 mg/kg/h (group CA) and 0.5 mg/kg/h (group R) was administered after recovery 5% of control The infusion rate was changed to maintain 90% twitch depression. The following pharmacodynamic parameters were studied Time to 25% and 95% depression of twitch height (TD25%, TD95%), recovery time 25–75% (RT), infusion rate (IR), and intubation twitch (ITw) Blood samples analysed for Tryptase concentrations were taken at regular intervals (baseline, 60 and 120 min) The results are presented as mean ± SD Statistical analysis was performed using Student's t-tests ($p < 0.05$ was considered significant)

Results:

	Group CA	Group R	
TD25% (sec)	100.5 ± 37	44.2 ± 16.5	p < 0.001
TD95% (sec)	263.7 ± 55.4	174 ± 51.3	p < 0.001
RT 25–75% (min)	10.8 ± 3.2	14.5 ± 4.3	p < 0.05
IR (mg/kg/h)	0.093 ± 0.009	0.56 ± 0.10	
ITw (%)	63.05 ± 28.3	30.7 ± 20.9	p < 0.001

Group/Intubating Conditions (n)	E	G	F	B
CA-1 (1.5 min)	1	8	1	–
CA-2 (2 min)	8	2	–	–
R-1 (1 min)	5	5	–	–
R-2 (1.5 min)	9	1	–	–

Conclusion: R may be an alternative to suxamethonium for rapid sequence induction R and CA do not induce significant Tryptase release

A.443 Mivacurium neuromuscular effects in elderly *vs* adult patients

R C Marcos, S. Garcia del Valle, T Delgado, S. Gonzalez, F. Duran
Department of Anaesthesiology, Hospital Puerta de Hierro, Madrid, Spain

Mivacurium is a short-acting nondepolarizing relaxant that is hidrolyzed by plasma cholinesterase We have compared the neuromuscular blocking properties in very old vs adult patients We have also examined the relationship of the duration of action to the plasma cholinesterases levels and the incidence of coughing and flushing

Methods: We included 40 adult (35 ± 16 yr) and 40 elderly patients (82 ± 14 yr), ASA I–II, undergoing elective orthopaedic surgery They were anesthetized with propofol, fentanyl and 60% N_2O in O_2 with 0.5–1% isoflurane Neuromuscular transmission was monitored by evoked adductor pollicis EMG (train-of-four stimuli at 10 sec intervals; Relaxograph™, Datex). Following a stable EMG response, a mivacurium bolus dose 0.2 mg/K (3 x DE_{95}) was given over 15 sec The data recorded were lag time (from injection to first decrease in T_1), latent time (time to 25% decrease in T_1), onset time (time to maximum block), clinical duration (time from injection to return of T_1 to 25% of control), recovery index (RI), time to recovery of TOF ratio to 0.7 (TOF 0.7) and the presence of flushing and coughing at intubation time (all of them with $T_1 < 5\%$) Data were analyzed by two tail t-test, ANOVA and Fisher's exact test ($p < 0.05$ vas considered significant).

Results: Table I shows no different onset characteristics in both groups, while recovery times, except RI, were significantly ($p < 0.001$) higher in elderly group. There was no correlation between recovery times and plasma cholinesterases levels when these were in normal range (3000–9000 U/L) although longest durations were with less than 3000 U/L. We have also seen high incidence of coughing, without difference in both groups, instead of very good intubating conditions, and significant higher incidence of flushing in adult patients ($p < 0.001$)

Neuromuscular data (mean ± SD)

	Onset*	T_1 25%**	RI	TOF 0.7**
Adult	192 ± 23 s	16 ± 7 min	8 ± 2 min	28 ± 7 min
Elderly	180 ± 34 s	27 ± 11 min	10 ± 5 min	41 ± 17 min

(* $p < 0.02$) (** $p < 0.01$)

Discussion: As in other studies, our results show longer (60%) clinical duration of mivacurium in elderly. The rather poor correlation of plasma cholinesterases levels with recovery times suggest the existence of other routes of metabolism. Finally, we think is necessary an objective neuromuscular monitoring method because of the high variability of recovery times in both groups

A.444 Assessment of intubating conditions in adults after induction with propofol and varying doses of remifentanil

S. Grant[1], S. Noble[2], A. Woods[2], J Murdoch[1], J.A H. Davidson[2].
[1] *Glasgow University Department of Anaesthetics, Glasgow Royal Infirmary, Glasgow;* [2] *Department of Anaesthetics, Victona Infirmary, Glasgow, UK*

Background & Goal of Study: Previous work in adults showed that tracheal intubation could be successfully achieved following induction of anaesthesia with alfentanil and propofol without the use of muscle relaxants. Given the pharmacokinetic profile of remifentanil it was hypothesized that it may be used in this application

Materials & Methods: In a prospective randomised double-blind trial, 60 ASA I–II patients with favourable airway anatomy were studied in 3 groups All patients were premedicated with temazepam 30 mg and ranitidine 150 mg Intubating conditions and the patients haemodynamic response to intubation were assessed pre-induction, post-induction and post-intubation with propofol 2 mgkg^{-1} and remifentanil 0 5, 1.0 or 2.0 μgkg^{-1}. Remifentanil was administered as a slow bolus over 30 seconds. Tracheal intubation was graded according to the ease of laryngoscopy, position of the vocal cords, coughing, jaw relaxation and movement of the limbs Parametric data was analysed using ANOVA. χ^2 analysis was applied to non-parametric data. $P < 0\ 05$ was regarded as significant

Results & Discussion: Intubation was successful in 80%, 90% and 100% of patients after remifentanil 0.5, 1.0 or 2 0 μgkg^{-1} respectively. Overall intubation conditions were regarded as excellent in 20%, 50% and in 80% of patients respectively with a significant difference between groups ($P < 0\ 05$). Blood pressure dropped in all 3 groups post-induction but not significantly No patients developed chest wall rigidity or a bradycardia The results presented here compare favourably with equally potent doses of alfentanil combined with propofol for intubation (1). Alfentanil has very variable metabolism (2) This may lead to apnoea when it is used to facilitate intubation of the trachea Remifentanil has a context-sensitive half-life of approximately 3 min. The short duration of action of may confer an advantage when used in tracheal intubation

Conclusion: Adequate conditions for laryngoscopy and intubation of the trachea were produced in premedicated adults following induction of anaesthesia with remifentanil 2.0 μgkg^{-1} as a slow bolus over 30 seconds, followed by propofol 2 mgkg^{-1}. Conditions with this dose were better than those obtained with remifentanil 0.5 or 1.0 μgkg^{-1}.

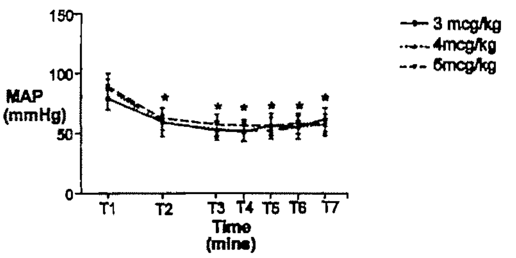
A.445 Comparison of three doses of remifentanil for intubation with no muscle relaxation in adults

R Alexander, A Olufolabi, J.V. Booth. *Department of Anesthesiology, Duke University Medical Center, Durham, NC, USA*

Background and Goal: Intubation without the use of muscle relaxants has been described[1] Remifentanil is a new opioid with a rapid onset of action and rapid clearance with short lived side effects[2] The hypothesis was to determine the dose of remifentanil required for good intubating conditions when administered with propofol.

Materials and Method: With IRB approval and informed written consent, 33 ASA 1 or 2 patients undergoing general anaesthesia with elective tracheal intubation were studied All patients were premedicated with midazolam 0.03 mg kg^{-1} iv. Routine monitoring was instituted and the patient preoxygented. Each patient was randomly allocated to one of three groups; remifentanil 3 mcg kg^{-1} iv (group A), 4 mcgkg^{-1} (group B) or 5 mcg kg^{-1} (group C) which was administered immediately after propofol induction (2 mg kg^{-1}). After one minute the patient was intubated by an anaesthetist blinded to the study drug and the conditions of intubation were scored as: 0) unable to intubate, 1) poor, 2) fair, 3) good and 4) excellent. Haemodynamic parameters were measured before induction (T 1), before intubation (T 2) and for every minute (T 3–7) after intubation for five minutes Ephedrine was given if the systolic blood pressure fell below 65 mmHg. Statistical analysis utilized SAS software and included shapiro-wilk test for normality, t-test or wilcoxon sign rank test as appropriate for nominal data, and chi-square test for categorical data.



Results: There was no difference in demographic data between the groups. The number of patients with good or excellent intubating conditions were: group A, 5* (n = 9); group B, 11 (n = 11); and Group C, 3 (n = 13); *$p < 0.0013$. Mean arterial pressure ± SEM is shown (fig., * $p < 0\ 05$).

Conclusion: Remifentanil 4 mcg kg^{-1} provides excellent intubating conditions compared with 3 mcg·kg^{-1} while associated with similar decreases in mean arterial pressure (37–40% decrease from pre-induction values).

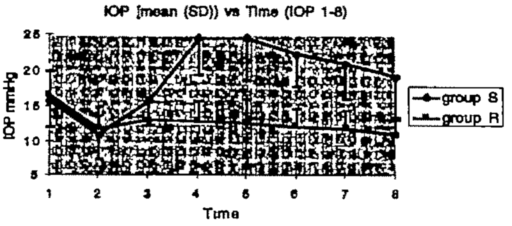
A.446 Use of remifentanil to prevent a rise in intraocular pressure following suxamethonium and intubation

R. Alexander, R Hill, W. Lipham, H El-Moalem, L. Gogineni. *Duke University Medical Center, Durham, North Carolina, USA*

Background and Goal: Suxamethonium and tracheal intubation increase intraocular pressure (IOP)[1] Remifentanil is a new potent opioid with a rapid onset of action and rapid clearance with short lived side effects[2]. We have compared the use of remifentanil with placebo to attenuate the rise in IOP following suxamethonium and tracheal intubation

Materials and Method: With IRB approval and informed written consent, 20 adults (ASA 1 and 2) undergoing elective eye surgery were studied They were premedicated with midazolam 0 03 mg kg^{-1} iv 10 minutes before anaesthesia. Routine monitoring was instituted and the patient preoxygented ·Each patient was randomly allocated to receive remifentanil 1 mcg kg^{-1} (group R) or saline (group S) Anesthesia was induced with propofol 2.0 mg kg^{-1} and the study drug was given immediately before suxamethonium 1 mg kg^{-1}. After one minute the patient was intubated by an anaesthetist blinded to the study drug. The patient was ventilated to normocapnia and anaesthesia maintained with isoflurane 1% and nitrous oxide 70% in oxygen. Intraocular pressure was measured in the unoperated eye immediately before induction (IOP 1, before study drug administration (IOP 2), before intubation (IOP 3) and every minute for five minutes (IOP 4–8) using a Tono-Pen by one of the authors (WJL) also blinded to the study preparation. Wilcoxon rank sum test was used for comparison of IOP and student T-Test for demographic analysis.

Results: Mean age was significantly different between groups R and S (45.8 yr SD ± 15 1 vs 59.7 ± 12 6 respectively) $P < 0\ 05$ There was a significant fall in mean IOP for both groups from IOP 1 to 2 ($P = 0.016$). The IOP rose significantly after administration of suxamethonium (IOP 3) ($P < 0.05$) and intubation (IOP 4–8) in group S compared with group R ($P < 0.001$)



Conclusion: Remifentanil 1 mcg kg^{-1} bolus attenuates the rise in IOP after administration of suxamethonium and tracheal intubation following propofol induction

A.447 Rational alfentanil administration improves haemodynamic stability during direct laryngoscopy under TIVA

M.O. Roussat, B. Ouaknine, J.L Bourgain, S. Bensaid, G. Mamelle, M.F. Cosset, V. Billard. *Institut Gustave Roussy, Villejuif, France*

Background: Direct laryngoscopy is a strong, brief noxious stimulus that may induce dangerous hypertension Opioids are added to propofol anaesthesia to limit this response. The goal of this study was to optimise alfentanil dosing scheme[1] in order to improve haemodynamic stability without additional side effects as hypotension or late recovery

Methods: Over a 6 months period, 2 groups of patients scheduled for direct laryngoscopy were studied. All received propofol (2.5 mg/kg then 10 mg/kg/h) and high frequency jet ventilation via intercricothyroid catheter (without intubation).

The first group (n = 19) received as usually in our hospital a single alfentanil iv bolus of 10 μg/kg, resulting in a predicted alfentanil plasma concentration ~50 ng/ml (Stanpump, Dr SL Shafer, Stanford) at the beginning of laryngoscopy. Then, the concentration fell dramatically in the next minutes.

In the second group of patients (n = 23), the alfentanil dose was designed in order to maintain a concentration ~50 ng/ml during the whole laryngoscopy The bolus was decreased to 6 μg/kg followed by an infusion of 0.8 μg/kg/min. Incidence of hypotension (SBP < 80 mmHg)[2] and hypertension (SBP > 160 mmHg) were compared between the 2 groups by c^2. Total doses of drugs (including the initial bolus) and delay to recovery were compared by t-test.

Results: The 2 groups were similar regarding to weight, age, duration of anesthesia, total dose of propofol and incidence of hypotension after induction, before laryngoscopy. Incidence of hypertension during laryngoscopy was significantly decreased when alfentanil was given as bolus + infusion (group 2)

Mean values	Group 1	Group 2
Duration of procedure (min)	18.8	16 1
Hypotension prior to laryngoscopy	2/19	3/23
Total alfentanil (μg/kg/min)	0.65	1.06 *
Total propofol (mg/kg/h)	19.1	21 9
Hypertension during laryngoscopy	8/19	3/23 *
Time to spontaneous ventilation (min)	7 1	5 9
Time to respond to command (min)	10 9	8 8

* $p < 0\ 05$, group 2 *vs* group 1

Discussion: Modifying the alfentanil dose scheme in order to maintain a stable plasma concentration during laryngoscopy decreases the incidence of hypertension when compared to a single iv bolus. It requires a lower bolus but a higher total dose of alfentanil This dose increase had no consequence neither on hypotension before nor on respiratory depression after the laryngoscopy. We conclude that such a bolus + infusion scheme could be recommended to improve safely haemodynamic stability during direct laryngoscopy.

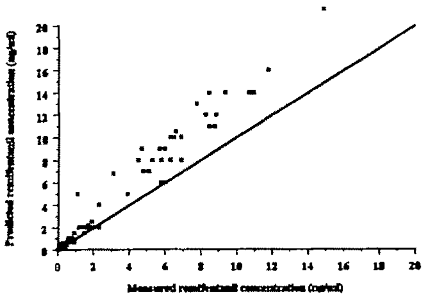
A.448 Predictive performance of a population pharmacokinetic data set of remifentanil in target-controlled infusion

M.J. Mertens, J. Vuyk, G. Broeders, A G L. Burm, J G. Bovill. *Dept. of Anaesthesiology, Leiden University Medical Centre and GlaxoWellcome, The Netherlands*

Background & Goal of the Study: The pharmacokinetics of remifentanil (REM) make it suitable for target controlled infusion (TCI). We studied the predictive performance of a TCI device when provided with a population pharmacokinetic data set of REM[1]

Materials and Methods: With ethics committee approval and informed consent, 6 ASA 1–2 female patients undergoing lower abdominal surgery received a TCI of REM and propofol (PROP). The target PROP concentration was maintained constant at 2–6 μg/ml, whereas the target remifentanil concentration was varied according to patient responses. Arterial blood samples were taken frequently for determination of the blood REM concentration The predictive performance was determined on the basis of the performance error[2], that was calculated as $((C_m - C_p)/C_p)^* 100$, where C_m and C_p are the measured and predicted REM concentrations Subsequently, the bias and inaccuracy were assessed as the median (MDPE) and the median absolute (MDAPE) performance error.,

Results and Discussion: A total of 91 arterial blood samples were analyzed. The MDPE and the MDAPE of the REM pharmacokinetic data set were −27% and 25%. Because the 95% confidence interval of MDPE (−30 4%—21 5%) did not include 0, it was concluded that a significant bias had occurred



Conclusions: The use of a population pharmacokinetic parameter set of REM in TCI during PROP anaesthesia results in a significant overprediction of the measured blood remifentanil concentrations

A.449 A prospective, randomized comparison of recovery times after remifentanil/propofol/oxygen, remifentanil/desflurane/oxygen, remifentanil/sevoflurane/oxygen and alfentanil/isoflurane/nitrous oxide anaesthesia for ENT surgery

T. Loop, H.-J Priebe. *Department of Anaesthesia University Hospital, 79106 Freiburg, Germany*

Background and Goal of Study: The pharmacokinetics of remifentanil (REM), desflurane (DES), and sevoflurane (SEV) make them highly attractive for ENT-surgery Accordingly, this study was to compare recovery times following REM/propofol (PRO), REM/DES, REM/SEV and alfentanil/isoflurane/N_2O/O_2 (control [CONTR]) anaesthesia

Materials and Methods: Following approval by the local Ethics Committee and written informed consent, 120 patients were randomly assigned to either REM/PRO, REM/DES, REM/SEV or CONTR anaesthesia (n = 30 each). Times from discontinuation of anaesthesia until return of spontaneous respiration, eye opening, and extubation, and from the time of extubation to statement of name and date of birth were determined Data were statistically analyzed by Kruskal-Wallis test, Mann-Whitney rank sum test and χ^2-analysis (significance level $p < 0.05$)

Results (Table) and Discussion: Patient characteristics were comparable between groups Compared to the REM groups, time intervals until extubation and statement of name and date of birth were considerably longer in the control group In the REM groups, return of spontaneous respiration, eye opening and extubation occurred almost simultaneously

Recovery characteristics (min)

	REM/PRO	REM/DES	REM/SEV	CONTR
Duration of anaesthesia				
	115 (48–286)	113 (57–353)	116 (74–332)	115 (48–188)
Time intervals from discontinuation of anaesthesia until				
Spont breathing	6 3 (2–11)	5 0 (1–11)	4 8 (1–10)	5 8 (0–17)
Eye opening	5 7 (1–11)	4 7 (1–11)	4 6 (1–10)	9 4 (3–23)*
Extubation	6 7 (2–13)	5 2 (1–11)	5 2 (2–10)	8 1 (3–24)*
Time intervals from extubation until statement of .				
Name	1 7 (1–8)	1 4 (1–4)	1 5 (1–4)	7 5 (1–29)*
Date of birth	1 7 (1–8)	1 4 (1–4)	1 5 (1–4)	7 9 (1–29)*

Values are means (range) *$p < 0\ 05$ vs other groups

Conclusion: Although the faster extubation in the REM groups may be of marginal clinical relevance (1.5–3 min difference), extubation in the REM groups was performed in much more responsive patients (as indicated by simultaneous eye opening and almost immediate statement of name and date of birth after extubation). This conveys an additional factor of safety and accelerates discharge of the patient from the operating room

A.450 A prospective, randomized comparison of postoperative patient comfort and satisfaction after remifentanil propofol/oxygen, remifentanil/desflurane/oxygen, remifentanil/sevoflurane/oxygen and alfentanil/isoflurane/nitrous oxide anaesthesia for ENT surgery

T. Loop, T. Klenzner[1], H.-J. Priebe. *Departments of Anaesthesia and Otolaryngology[1] University Hospital, 79106 Freiburg, Germany*

Background and Goal of Study: The pharmacokinetics of remifentanil (REM), desflurane (DES), and sevoflurane (SEV) make them highly attractive for ENT-surgery Accordingly, this study was to evaluate patient comfort and satisfaction following REM/propofol (PRO), REM/DES, REM/SEV and alfentanil/isoflurane/N_2O/O_2 (control[CONTR]) anaesthesia.

Materials and Methods: Following approval by the local Ethics Committee, 120 patients were randomly assigned to either REM/PRO, REM/DES, REM/SEV or CONTR anaesthesia (n = 30 each). Visual analog scores (VAS, 0[best]–10[worst]) for pain, nausea and sleepiness were evaluated at 30 and 90 min, and 4 and 24 h, and VAS for patient satisfaction at 48 h post extubation Data were analyzed by Kruskal-Wallis and Mann-Whitney rank sum test (significance level $p < 0\ 05$)

Results (Table) and Discussion: Patient characteristics were comparable between groups. At 30 and 90 min, nausea-VAS was lower following

REM/PRO, and sleepiness-VAS higher following CONTR compared to the other groups. Satisfaction-VAS were comparable between groups.

Visual analog scores (VAS) (0 [best]–10 [worst])

	REM/PRO	REM/DES	REM/SEV	CONTR
Pain-VAS				
30 min	2.6 (0–7.2)	3.5 (0–7.0)	3.3 (0–8.3)	3.2 (0–8.5)
90 min	2.1 (0–4.9)	2.5 (0–7.1)	2.1 (0–7.9)	2.8 (0–8.4)
4 h	1.4 (0–8.9)	1.6 (0–5.7)	1.7 (0–9.2)	1.6 (0–4.9)
24 h	1.4 (0–4.9)	1.0 (0–6.6)	0.8 (0–5.7)	1.3 (0–6.9)
Nausea-VAS				
30 min	0.2 (0–2.1)*	1.7 (0–5.1)	1.5 (0–7.2)	2.0 (0–6.7)
90 min	0.1 (0–1.5)*	1.5 (0–7.5)	1.2 (0–7.3)	1.3 (0–7.3)
4 h	0.6 (0–4.7)	0.8 (0–6.4)	0.6 (0–3.8)	0.6 (0–7.2)
24 h	0.2 (0–3.1)	0	0.1 (0–1.3)	0.3 (0–3.3)
Sleepiness-VAS				
30 min	3.2 (0–9.1)	3.4 (0–6.6)	3.4 (0–8.3)	4.9 (0.8–9.0)*
90 min	2.4 (0–10)	2.4 (0–6.0)	1.8 (0–9.1)	3.0 (0–9.1)*
4 h	1.2 (0–6.1)	1.5 (0–5.8)	1.5 (0–6.3)	1.4 (0–10)
24 h	0.8 (0–9.4)	0.3 (0–5.0)	0.3 (0–2.6)	0.8 (0–6.6)
Satisfaction-VAS				
	0.6 (0–5.4)	1.1 (0–10)	0.5 (0–3.6)	0.6 (0–6.9)

Values are means (range) *$p < 0.05$ vs other groups

Conclusion: Our results indicate less nausea following REM/PRO, and faster recovery of alertness following all REM-based anaesthetics in the early postoperative period. Patients appear equally satisfied with all four anaesthetic regimens.

A.451 Effect of premedicated oral ketamine on reducing the pain both on injection of propofol and on placing the venous catheter

M. Uchiyama, A. Yoshino, S. Nagashima, Y. Hashimoto, J. Hirashima.
Department of Anesthesiology, Nihon University School of Medicine, Tokyo, Japan

Introduction: To reduce the incidence of pain on injection of propofol we studied the effects of pretreatment by 0.2 mg/kg ketamine intravenously and showed that it provides satisfactory pain relief. We, however, supposed that premedicated ketamine may reduce the pain when inserting venous catheter as well. We, therefore, studied a double-blind comparison of premedicated oral ketamine and a placebo of the incidence of pain both on injection of propofol and on insertion of a venous catheter.

Methods:

After acquiring Institutional Ethical Committee clearance and informed consent, 48 (ASA 1 or 2) patients scheduled for ENT surgery were studied. Patients were randomly assigned to receive either only 5 ml syrup (group S, n = 24) or 2 mg/kg ketamine in syrup (group KS, n = 24) on a double-blind bases one hour prior to anaesthesia induction. Upon arrival in the operating room, a 20 G catheter was placed in the largest vein of the non-dominant hand or forearm Patients were asked to assess the severity of pain from 0 for none to 3 for severe. Anaesthesia was induced with 2 mg/kg propofol at the rate of 300 ml/h and patients were asked if they had a stinging feeling in their arms. On the day after operation patients were also asked if they could recall the venous catheter and if they had memory of pain in the arms during the induction of anaesthesia.

Results: The patients in group KS were well sedated before induction. The pain on placing the catheter was significantly lower in group KS (median 1.5, range 0–3) than in group S (median 2, range 1–2) In group KS 83.3% of the patients had no pain on infusion of propofol, as did 25% in group S. Patients who could not recall having catheter and pain on infusion were 75% and 66.7% in group KS and 16.7% and 12.5% in group S.

Discussion: The statistically significant difference in number of the patients who had pain on receiving the venous catheter and on injection of propofol between Group S and Group KS suggests that premedicated oral ketamine provides satisfactory pain relief for both. Most patients in Group K did not recall the venous catheter regardless of the level of pain on insertion or their level of consciousness, this may be helpful in allowing patients to overcome a difficult operation.

Conclusion: When combined with an adequate level of sedation orally premedicated 2 mg/kg ketamine is a good method as it provides satisfactory pain relief not only during injection of propofol but also when inserting a venous catheter.

ABSTRACT WITHDRAWN

A.454 Low-dose droperidol (0.625 mg, 1.25 mg and 2.5 mg) has no effect on postoperative anxiety, restlessness and overall mood

A.M. Monn, T. Bezler, L H J Eberhart, R Maier, M. Schreiber, J Kilian, M. Georgieff. *Department of Anaesthesiology, University of Ulm, Germany*

Background: Droperidol (D) in low doses such as 1 25 mg [1] or even 1 mg and 0 5 mg [2] can increase anxiety and restlessness in the postoperative period. The aim of this study was to determinate whether these side effects indeed occur frequently following low-dose D and to see if this is dose related.

Methods: 184 female patients ASA grade 1 and 2 undergoing gynaecological laparoscopy were recruited to this prospective, double-blinded study. General anaesthesia was performed in a standardized manner (induction with thiopentone, fentanyl 2μg/kg and vecuronium 0 1 mg/kg, tracheal intubation, maintenance with enflurane in N_2O/O_2). Patients were randomly allocated to receive saline (n = 45), D 0.625 mg (n = 47), D 1.25 mg (n = 46) or D 2.5 mg (n = 46) i v 10 minutes before the end of surgery. Preoperatively, and 1, 3, 6, and 24 hours postoperatively, the patients' anxiety, restlessness, and overall mood was evaluated using two psychological questionnaires (Erlanger anxiety and tension-scale/BSK-test). Sedation was evaluated by a subtest of the BSK-test. Statistical analysis was performed using the Kruskal-Wallis and the Wilcoxon-test as a posthoc test. Furthermore, postoperative nausea and vomiting (PONV) was assessed with a 100 mm visual analogic scale and by counting the episodes of retching and vomiting. PONV was then rated as none, mild, moderate or severe using a fixed scoring algorithm. The χ^2-test was used for statistical analysis

Results: All groups were comparable for biometric data, duration of surgery and anaesthesia and possible risk factors for PONV

The scores for anxiety, restlessness and overall mood were not significantly different between the groups at any observation time Quality of sleep in the first night after surgery was the same in all groups. Only the sedation scores were significantly different 1 h (p = 0.011) and 3 h (p = 0.011) postoperatively in a dose-dependant manner, but duration of stay in the recovery room did not differ.

Compared to placebo, PONV was significantly reduced by D (p = 0 012, see table)

PONV	Placebo	0 625 mg	1 25 mg	2 5 mg
None	42 2%	70 2%	54 3%	73 9%
Mild	22 2%	10.7%	8 7%	17 5%
Moderate	15 6%	10 6%	15.3%	2 1%
Severe	20%	8 5%	21 7%	6 5%

Conclusion: Droperidol is an effective antiemetic drug and it does not influence postoperative anxiety, restlessness and overall mood in female patients undergoing gynaecological laparoscopy

A.455 Dimenhydrinate reduces the incidence of postoperative nausea and vomiting in female inpatients

L H J. Eberhart, T.I. Bopp, A M Monn, M Georgieff, W. Seeling. *Department of Anaesthesiology, University of Ulm, Germany*

Background: Dimenhydrinate (D) is an inexpensive antihistaminic drug, that is frequently used as an antiemetic in anaesthesia [1] The popularity of the drug is contrasted by the lack of modern studies concerning its efficacy in reducing the incidence of PONV [2]. Thus, dimenhydrinate was compared to placebo (P) in a prospective, randomized, double-blind study.

Methods: 133 female inpatients undergoing orthopaedic surgery were studied. General anaesthesia was induced with etomidate, fentanyl (2 μg/kg), vecuronium, and maintained with enflurane in N_2O/O_2 Neuromuscular block was reversed with pyridostigmine/atropine in all patients. Patients in the D-group (n = 67) received 62 mg dimenhydrinate i v. after induction of anaesthesia. P-patients (n = 66) received saline. Administration of dimenhydrinate (and placebo) was repeated three times postoperatively over a period of 24 hours to ensure constant plama levels of the drug, due to its short half life Postoperative analgesia was achieved by metamizole, diclofenac and piritramid on demand Patients were observed over a 48 hour period postoperatively Episodes of vomiting, reaching and need for additional antiemetics were recorded. Nausea was assessed using a 100 mm visual analog scale (VAS). PONV was rated as "none", "mild", "moderate", and "severe" using a fixed scoring-algorithm. Statistical analysis was performed using the χ^2-test

Results: There were no differences between the two groups with regard to biometric data, type of surgery, history of PONV or motion sickness In the D-group the incidence of PONV was significantly reduced compared to placebo (see table, p = 0 0024) The incidence of side effects (dry mouth, blurred vision) was the same in both groups

Severity of PONV	Dimenhydrinate	Placebo
None	26 (38 8%)	10 (15 1%)
Mild	13 (19 4%)	11 (16 7%)
Moderate	18 (26 9%)	19 (28 8%)
Severe	10 (14 9%)	26 (39 4%)

Conclusion: Dimenhydrinate is a safe and effective antiemetic in female inpatients, when its administration is repeated 3 times postoperatively over a period of 24 hours.

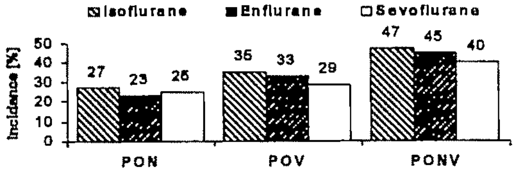
A.456 Sevoflurane does not reduce postoperative nausea and vomiting compared with enflurane and isoflurane

P Kranke, C C Apfel, T. Papenfuss, B Schafers, P Sefrin, N Roewer
Department of Anaesthesiology, University of Wurzburg, D-97080 Wurzburg, Germany

Background: Postoperative sequelae such as nausea (PON), vomiting (POV) and nausea and vomiting (PONV) still frequently occur after ENT- and squint-surgery. Maintenance of general anaesthesia with sevoflurane is thought to reduce the incidence of PONV (1) Therefore we evaluated the efficacy of sevoflurane in order to reduce PONV in patients with increased risk according to a previously developed risk score (2)

Materials and Methods: With approval of the local ethics committee and written informed consent 657 ASA 1 to 3 patients scheduled for elective ENT- and strabismus-surgery were randomly assigned to one of three groups Standardized general anaesthesia was stratified After induction with thiopentone patients received isoflurane (group 1, n = 236), enflurane (group 2; n = 239) or sevoflurane (group 3, n = 182) in N_2O/O_2 2:1. Due to stratification the allocation of opioids (equianalgesic doses of fentanyl, alfentanil and sufentanil) and antiemetics (droperidol, dimenhydrinate, tropisetron and metoclopramide) were similar for all groups. Emetic episodes as well as nausea were recorded over 24 hrs according to a standardized protocol. Statistical analysis were performed using the chi-square test with p < 0 05 considered as statistically significant and power analysis revealed a minimum of 174 patients for a calculated reduction from 30 to 15% (α = 0.05 and β = 0 1).

Results: There were no significant differences among the groups with regard to patient demographics and surgical procedures There was no statistical difference as regards the incidence of emetic symptoms (PON, POV and PONV) between group 3 (25%, 29% and 40%) compared to group 1 (27%, 35% and 47%) and group 2 (23%, 33% and 45%) respectively



Conclusion: The data suggest that with respect to emetic sequelae sevoflurane fails to show any beneficial effect compared to enflurane and isoflurane.

A.457 Comparative study of the effect of desflurane with nitrous oxide *vs* desflurane without nitrous oxide on postoperative nausea and vomiting in female patients undergoing breast surgery

B F. Vanacker. *Department of Anaesthesiology, K U Leuven, U.Z. Gasthuisberg, Herestraat 49, 3000 Leuven, Belgium*

Background & Goal of Study: A recent meta-analysis showed that omitting N2O significantly reduced postoperative nausea and vomiting (PONV) compared with a N2O regime (1) Our study was designed to evaluate the effect of the combination of desflurane with N2O versus desflurane alone on PONV in a subgroup of female patients and PONV was considered as the primary endpoint (2).

Materials & Methods: After approval of the local ethics committee and informed consent 60 female patients (ASA 1&2), aged 18–65 y, and scheduled for breast surgery with a duration of 1–3 h were included. Obese patients or patients with a history of PONV and motion sickness were excluded No prophylactic anti-emetic therapy was allowed during the study Patients received a standardized anaesthetic technique consisting of propofol for induction, vecuronium and fentanyl for intubation, followed by desflurane with or without N2O (randomisation list) and fentanyl supplements if required for maintenance of anaesthesia. At the end of anaesthesia PONV was recorded during 24 h in different periods Data of incidence and severity of PONV and use of rescue medication were gathered at the end of each period Statistical evaluation was performed using t-test, chi-square test or Cox log rank test and $p < 0.05$ was considered significant

Results: There were no significant differences between the groups with respect to demographic data and duration of anesthesia. In addition, there were no significant differences in the amount of intraoperative fentanyl or postoperative narcotics. The incidence of PONV was significantly higher in the group of patients receiving desflurane in N2O-O2 mixture compared with the group receiving desflurane in AIR-O2 mixture (table 1)

	Group N2O (n = 30)	Group No N2O (n = 30)	Statistical Signifance
PONV	17	6	p = 0.0035
Nausea	17	5	p = 0.0013
Vomiting	12	5	p = 0.0449
Rescue	15	5	p < 0.005

Conclusion: The combination of desflurane with N2O in female patients undergoing breast surgery is associated with a significantly higher incidence of PONV and a higher need of antiemetic drugs.

A.458 Ondansetron is more effective than metoclopramide in the treatment of opioid-induced emesis in post-surgical adult patients

F. Chung[1], R Lane[2], C. Spraggs[2]. [1]*Toronto Hospital, University of Toronto, Canada;* [2]*Gastrointestinal Clinical Research, Glaxo Wellcome Research & Development, Greenford, UK*

Background and Goals: Nausea and vomiting are common side-effects of opioids given for pain control This study evaluated the efficacy and safety of ondansetron and metoclopramide in the treatment of OIE in post-surgical patients

Materials and Methods: A double-blind, randomised, parallel-group study compared single iv doses of ondansetron (ond) 8 mg, 16 mg and metoclopramide (met) 10 mg in the treatment of OIE in patients receiving parenteral opioid analgesia post-surgically. Emesis related to surgery itself was minimised by restricting patient entry to adult patients undergoing surgery types with low emetogenicity. Patients who required antiemetic within 6 h of receiving their first dose of post-surgical opioid were assessed for 24 h following study drug The proportions of patients who experienced complete control (ie no emetic episodes, no nausea, no rescue antiemetic medication and no withdrawal) at 24 h were compared (Mantel-Haenszel chi-squared test).

Results and Discussion: Of the 4511 patients enrolled, 1380 had OIE and received study medication. Preliminary results showed that ond 8 mg and ond 16 mg were significantly better than met 10 mg in controlling emesis and nausea ($p < 0.02$). There was no significant difference between the two ond groups ($p > 0.05$). The incidences of adverse events were low in all three treatment groups (14%–17%) (figure).

Conclusions: Preliminary data found that ond 8 mg and ond 16 mg iv were effective in the treatment of OIE following opioids administered post-surgically. No difference in efficacy was observed between the two ondansetron doses, but both were significantly better than met 10 mg

Acknowledgements: The authors thank the investigators who contributed to the study

A.459 Comparison of ondansetron and cyclizine in the treatment of early postoperative nausea and vomiting

K Kynakides, S Hussain, J. Harrison, A Webb, G. J Hobbs. *University Department of Anaesthesia, Queen's Medical Centre, Nottingham, NG7 2UH, UK*

Background and Goal of Study: There is little published information on the treatment of postoperative nausea and vomiting (PONV) in the recovery ward, despite a suggested incidence of at least 10% [1] We compared the efficacy of ondansetron and cyclizine for the treatment of this problem

Methods: After Ethics Committee approval 250 patients of a mixed surgical cohort and experiencing nausea and/or vomiting in recovery were studied using a double-blind crossover design The severity of nausea and pain (4 point ordinal scales) and presence of vomiting were assessed by nursing staff. Patients were then allocated randomly to receive either iv ondansetron 4 mg (O) or iv cyclizine 50 mg (C) as initial treatment After 30 min symptoms were re-assessed and if further treatment was required escape (crossover) drug was given. Patients not responding to both drugs after a further 30 min were 'non-responders' Demographic (age, gender and weight), anaesthetic drug (pre-medication, induction, maintenance and analgesia), operation (type and duration) and recovery opioid data were also collected The primary outcome measure was the number of patients requiring escape treatment Chi-square and Student's t tests were used to analyse data $P < 0.05$ was considered statistically significant

Results: Incomplete data from 25 (O) and 24 (C) patients were rejected. Initial and 30 min nausea and pain scores, incidence of vomiting as well as demographic, anaesthetic and operation data were comparable between groups. 64% and 42% of patients in groups O and C respectively, received opioids in recovery ($P < 0.01$). The table shows the number of patients requiring escape treatment and non-responders

Group	Escape	Non-responders
O (n = 100)	24*	1
C (n = 101)	39	0

* $P = 0.026$

Conclusions: Although more patients in group O received opioids in recovery, this regimen was significantly more efficacious in the management of early PONV However, the use of ondansetron and cyclizine, in any order, is highly effective Economic evaluation suggests that although drug costs are higher using ondansetron as initial therapy, this may be offset by the smaller number of patients requiring escape treatment with benefits for the use of nursing time.

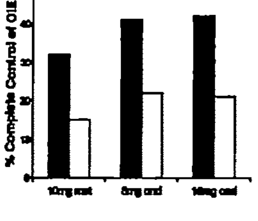
A.460 Systemic *vs* single ondansetron administration in preventing nausea and vomiting as well as pruritus after intrathecal morphine administration

V Dimitriou, G S. Voyagis, G. Tsiganos, A. Douma, A Malefaki, C Pratsas *Departments of Anaesthesia, G. Gennimatas and Sotiria Hospitals, Athens, Greece*

Background: The intrathecal administration of opioids is a simple and reliable method of providing long-acting postoperative pain relief. However postoperative nausea and vomiting (PONV) as well as pruritus seem to be important and frequent side-effects. It seems that ondansetron is effective in the prophylaxis of PONV. In addition it is postulated that ondansetron is a promising agent in the prevention of pruritus (1). In a double-blind randomized study we compared the efficacy of different regimens of ondansetron with placebo, in the prevention of PONV as well as pruritus following orthopaedic surgery, when using intrathecal morphine for postoperative pain relief.

Materials and Methods: In the study were included 65 patients, ASA I–III, aged 35–75 years and were given subarachnoid injection of plain



bupivacaine 0.5% mixed with morphine 0 3 mg for surgical and postoperative analgesia. Patients were randomly allocated in 3 groups. In group 1 (n = 21) they received i v. 2 ml of saline 20 min before the spinal, as well as at 12, 24, 36, 48 hours after surgery In group 2 (n = 24) patients received i.v ondansetron 4 mg 20 min before the spinal and i.v. saline 2 ml at 12, 24, 36, 48 hours after surgery. In group 3 (n = 20) ondnsetron 4 mg was given i v. 20 min before the spinal and at 12, 24, 36, 48 hours after surgery. In the postoperative period nausea scores, vomiting as well as pruritus scores and pain relief were recorded every 4 h interval over a period of 48 h

Results: Postoperative pain relief was excellent in all groups. Our results are summarized in the table.

Group	1	2	3
Nausea	12/21 (57.1%)	6/24 (25 0%)	5/20 (25%)
Vomiting	11/21 (52.4%)	5/24 (20 8%)	4/20 (20.0%)
Pruritus	15/21 (71 4%)	15/24 (62 5%)	9/20 (45 0%)

Fisher's exact test Nausea 1 vs 2 p = 0 03, 1 vs 3 p = 0 04, 2 vs 3 NS, Vomiting 1 vs 2 p = 0 03, 1 vs 3 p = 0 03, 2 vs 3 NS, Pruritus 1 vs 2 NS, 1 vs 3 p = 0 08, 2 vs 3 NS

Conclusion: Systemic i.v. administration of ondansetron is effective in the prevention of PONV after intrathecal morphine administration, but seems to offer no advantage over the single ondansetron administration. However the systemic i.v. ondansetron administration seems to be more effective in the prevention of pruritus

A.461 Influence of intrathecal combination of clonidine with morphine on nausea and vomiting as well as pruritus

G.S Voyagis. V. Dimitriou, A Douma, E. Miriati, E. Koukou, G. Tsiganos.
Departments of Anaesthesia, Sotiria and G. Gennimatas Hospitals, Athens, Greece

Background: The intrathecal administration of opioids is a simple and reliable method of providing long-acting postoperative analgesia. The addition of clonidine to intrathecal bupivacaine increases both the duration of motor and sensory block as well as the duration of postoperative analgesia (1). It has been stated the theoretical hypothesis that the combination of alpha-2 agonists with opioids provides very durable analgesia with fewer side-effects than if either were used alone (2) In a double-blind randomized study we compared the efficacy of intrathecal clonidine in preventing postoperative nausea and vomiting (PONV) as well as pruritus, following major orthopaedic surgery, when using intrathecal morphine for postoperative pain relief

Materials and Methods: In the study were included 46 patients ASA I-III, aged 40–75 years well matched for characteristics and were given a subarachnoid injection of plain bupivacaine 0.5% mixed with preservative-free morphine 0.3 mg alone (group 1, n = 21) or with the addition of clonidine 1 μg/kg (group 2, n = 25) In the postoperative period nausea scores, vomiting as well as pruritus scores and pain relief were recorded every 4 h over a period of 48 h.

Results: Postoperative pain relief was excellent in both groups. Our results are summarized in the table·

Group	1	2	P-value*
Nausea	12/21 (57 1%)	4/25 (16 0%)	0 005
Vomiting	11/21 (52 4%)	3/25 (12 0%)	0 004
Pruritus	15/21 (71 4%)	8/25 (32 0%)	0 02

*Fisher's exact test

Conclusion: Our findings confirmed experimentally that the intrathecal combination of clonidine with morphine is very efficient in preventing PONV as well as pruritus

A.462 Clonidine premedication in middle ear microsurgery

J. Marchal, M. Poncela, J Rosell, A. Gómez, J. Cervantes, M.C Martínez, A Delgado. *Department of Anaesthesia, Hospital Princesa de España, Jaén, Spain*

Background and Goal of Study: Clonidine premedication has been used for isoflurane-induced hypotension during middle ear microsurgery to provide a relatively bloodless field (1–3) The purpose of this study was to determine if a single-dose oral clonidine premedication would 1) reduce the requirement of isoflurane and urapidil to get the desired hypotension and 2) decrease bleeding in patients undergoing middle ear surgery

Material and Methods: The study was approved by the local ethics committee, and informed consent was obtained from all patients Thirty one patients were designed randomly in two groups 14 received 0 3 mg clonidine p.o 1.5 h before surgery. The other 17 received placebo and served as a control group. The standardized general anaesthesia included propofol, isoflurane, N2O, fentanyl and atracurium. Bleeding was evaluated in four categories: from 0 (no bleeding) to 3 (severe) Data was analyzed throughout ANOVA.

Results: Mean age of patients was 38 2 yr ± 11 3 (clonidine) and 42 4 yr ± 13 2 (placebo), 11 male and 20 female, ASA I-III. The isoflurane concentration administered was lower in the clonidine group (0 64 ± 0 1 clonidine vs 0.96 ± 0 2 placebo, p < 0 001) The dosages of supplementary urapidil showed no differences between groups The quality of the surgical field was better in the clonidine group (1 1 ± 0 4 clonidine vs 0 74 ± 0 3 placebo; p < 0 05) Arterial blood pressure and heart rate were significantly lower in the clonidine group at intubation and postintubation No statistical differences were found in adverse effects between groups.

Conclusions: Clonidine premedication before anaesthesia was helpful in decreasing consumption isoflurane-induced hypotension and bleeding during ear surgery

A.463 Effect of clonidine premedication on the induction dose of propofol and haemodynamic parameters

M Subrahmanyam, M Rea, R. Cooper *Musgrave Park Hospital, Belfast, UK*

Introduction: Clonidine is an alpha$_2$ agonist representing a new class of drugs being increasingly used in anaesthetic practice[1] Clonidine is known to have sympatholytic, anxiolytic, analgesic, anaesthetic-sparing and intra-operative haemodynamic-stabilizing effects[1]. Very little information is available on the effect of clonidine on the induction dose of propofol[2]

Aim: To determine the induction dose of propofol after oral clonidine premedication or placebo and to study the consequent haemodynamic effects, in a prospective, randomized, double blind study.

Methods: After ethical committee approval, 60 ASA I/II patients scheduled to undergo minor day procedure surgeries were randomly allocated to receive either clonidine 300 mcg (Gr1) or placebo (Gr2) as oral premedication 90 mins prior to the surgery Propofol was administered at the rate of 10 mg every 5 seconds till loss of verbal contact with patient Heart Rate (HR) and blood pressure (BP) were measured before (baseline), just after and 1, 3, 5 minutes after administration of sleep dose Recovery time was noted from turning off isoflurane to the patient stating their name Results were analysed with students t test and ANOVA

Results: Both groups were demographically matched for all variables The induction dose of propofol was significantly lower in the clonidine group than in placebo The recovery times were not significantly different Table shows mean ± S.D.

	Clonidine	Placebo	Significance
Induction Dose. mg/kg	1 74 (± 0 44)	2 08 (± 0 57)	P < 0 05
Recovery Time (mins)	9 84 (± 3 56)	8 44 (± 3 72)	None

The heart rate was significantly lower in the clonidine group compared to the placebo group at all intervals studied, as were the blood pressures (P < 0.01). Using ANOVA, the HR in the clonidine group did not change from the baseline, whereas in the placebo group it increased significantly at the 5 minute interval (P < 0.001). The blood pressure in the clonidine group was lower at all intervals compared to the base line (P < 0 001) Whereas in the placebo group, only the systolic BP was lower at all intervals compared to base line (P < 0.001)

Conclusion: This study shows that oral clonidine premedication reduces induction dose of propofol and decreases the heart rate and blood pressure when compared to the placebo The recovery times are similar in both groups

A.464 Emergence and recovery from desflurane or isoflurane prolonged anaesthesia for acoustic neuroma surgical procedures

D. Boisson-Bertrand[1], M.C. Laxenaire[1], G. Lapeyre[2]. [1]*Service d'Anesthésie-Réanimation, CHU Nancy;* [2]*Laboratoire Pharmacia & Upjohn, St Quentin en Yvelines, France*

Background and Goal of Study: The occurrence of a cerebellopontine angle hematoma is the major post-operative risk after acoustic neurinoma surgery by translabyrinthic approach. Therefore the necessary neurological post-operative assessment would benefit from a clear and rapid recovery. Desflurane (D) with its fastest kinetic profile among halogenated agents[1] could be a suitable alternative to the commonly used isoflurane (I) in this long-lasting surgery requiring also a smooth, deep and stable anaesthesia[2].

Materials and Methods: After institutional approval and informed consent, 30 patients selected for this surgery were randomized to receive either D or I in 50: 50 N_2O-O_2 mixture (1 L fresh gas flow) to maintain anaesthesia. Analgesia consisted in sufentanil continuous infusion (0.15 to 0 30 μg/kg). Times from end of anaesthesia to spontaneous breathing (SB), extubation, eyes opening, hand squeezing to command, ability to state name, birthdate and phone number were recorded together. The Steward recovery score was recorded also every 5 minutes during the 20 first post-operative minutes and then every 10 or 15 minutes. Statistics: Student T test bilateral, Wilcoxon rank sum test bilateral, Fisher exact test bilateral

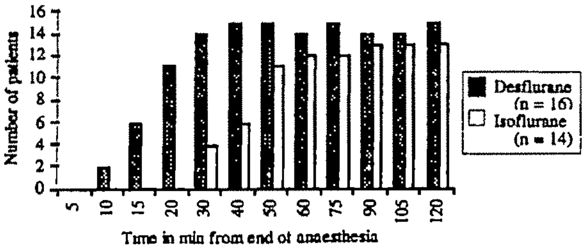

Fig. 1 Patients with Steward score to 6

Results and Discussion: The groups were similar regarding patients characteristics, depth of anaesthesia, sufentanil total dose, anaesthesia duration (D: 348.1 ± 18.9; I: 348.9 ± 22 8 min), hemodynamic/respiratory parameters and surgical conditions assessed by bleeding score. The emergence time was significantly more rapid in the D group and the orientation (ability to answer to name, birthdate and phone number) was fully recovered earlier in the D group. Steward scores were also better during the first post-operative hour in D group.

Times to recover (in min) after D vs I anaesthesia

	SB	Extubation	Eyes opening	Hand squeezing	Name	Birthdate	Phone number
D	9 7 ± 1 2	14 1 ± 2.4	14.9 ± 2.4	19.6 ± 3.0	22.1 ± 3.1	22.4 ± 3.1	24.3 ± 3.6
I	17 1 ± 1.4	26 1 ± 2 4	30 6 ± 2 7	34 2 ± 3.8	39 1 ± 4 6	46 5 ± 10 2	50 4 ± 10 3
p	≤0 001	0 001	0 001	0 005	0 006	0 039	0 029

Conclusion: Anaesthesia maintenance with D leads to similar preoperative conditions but allows a more rapid and clearer recovery in comparison with I. This recovery is particularly suitable after long-lasting surgical procedures justifying the full patients cooperation to make an early diagnosis of any neurological alteration.

A.465 Effects of nitrous oxide as second gas during desflurane anaesthesia

P Garrido, M V. Caldera, E. Deudero, M.J. Villagrán, B. Martínez, A. Criado *S. Anestesiologiá y Reanimación, Hospital La Paz, Madrid, Spain*

Background & Goal of Study: We have studied how N_2O influences desflurane uptake velocity in a heterogeneous population of adult patients.

Material & Methods: 50 patients scheduled for abdominal surgery under general anesthesia were randomly distributed in two groups: DNO (Desflurane – N_2O 60% – O_2 40%) and DAO (Desflurane – Air – O_2 40%) Desflurane was administered in both groups at 1.3 MAC-awake dose with an Ohmeda TEC-6 vaporizator (open circuit) with a fresh gas flow of 100 ml/kg. Desflurane uptake at 1, 5, 10, 15, 30 and 60 minutes was measured as the value of the Fet/Fi ratio (1, 2).

Results & Discussion: Desflurane uptake was higher in the DNO group in respect to DAO group at 5, 10, 15, 30 and 60 minutes. (Table 1)

Table I Percent uptake of desflurane in respect to the inspired concentration

	FET/FI (%)					
	1 m	5 m	10 m	15 m	30 m	60 m
DNO	68 6 (17.1)	88 0 (7 4*)	93 6 (5 1*)	94.6 (4 1*)	95 2 (3 8*)	95 8 (3 2*)
DOA	62.8 (9 5)	80 7 (3 5)	85 0 (3 8)	87 6 (3 8)	89 6 (2 9)	90 9 (3 3)

(*) p < 0 05

Conclusions: N_2O increases desflurane uptake velocity due the second gas effect. In order to achieve similar uptake rates without N_2O it is necessary to increase proportionally the desflurane Fi.

A.466 Recovery profile of desflurane, propofol and isoflurane anaesthesia in morbidly obese patients: preliminary results

P Vila, J. Canet, C. Bertrán, E. Massó, E Mata, F Vidal *Dept of Anaesthesiology, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain*

Background & Goal of Study: Obesity is associated with physiologic changes that may alter drug disposition Fast recovery from anaesthesia is desirable so that airway patency can be reestablished and so that the patient can collaborate in chest physiotherapy. We compare the recovery time from desflurane (DES), propofol (PRO) and isoflurane (ISO) anaesthesia in morbidly obese patients undergoing bariatric surgery.

Material & Methods: After institutional approval and informed consent, 17 morbidly obese patients (14 females) with body mass index (BMI) as greater than 40 $kg.m^{-2}$ were enrolled in the study. Anaesthesia was induced with fentanyl 2 $\mu g.kg^{-1}$ and propofol 1.5 $mg.kg^{-1}$; succinylcholine was used to facilitate tracheal intubation. Anaesthesia was maintained with either DES, PRO or ISO in O_2: N_2O 50% and continuous infusion of atracurium. Fentanyl 1 $\mu g.kg^{-1}$ was injected every 30 min, or depending on patient requirements. End-tidal CO_2 pressure was recorded continuously to adjust minute ventilation Times to eye opening, to extubation, to verbal command and orientation to name and date of birth were recorded Statistical analysis was performed with one way analysis and significance considered at $p < 0.05$.

Results: The study groups were demographically similar Values are expressed as means (SD).

	DES (n = 5)	PRO (n = 6)	ISO (n = 6)
Age (y)	34 6 (8)	47.6 (7)	40 5 (11)
Weight (cms)	149 (38)	145 (37)	139 (26)
BMI (kg m^{-2})	59 (14)	53 (11)	51 (7)
Eye open (min)	7 2 (2 7)	5 6 (2 1)*	12 9 (4 4)
Extubation (min)	15.5 (8 7)	10 5 (6)	14 8 (5 2)
Orientation (min)	16 5 (8 6)	11 2 (6 2)	16 9 (5.1)

*P < 0 05 from DES and ISO.

Conclusions: In spite of a tendency for shorter times in the propofol group, only time to eye opening was significantly shorter. Duration of anaesthesia and opiates and muscle relaxant requirements were similar in all groups. In view of these preliminary results the study should be extended, enrolling a larger number of morbidly obese patients

A.467 Isoflurane enantiomers in humans

H.A Häberle, H.G. Wahl, H.J. Jakubetz, V. Schurig, H Krause, R. Schmidt, K. Unertl, H.J. Dieterich *University of Tuebingen, Department of anaesthesiology, Germany*

The isoflurane molecule has an asymmetric C- atom, the routinely used isoflurane is a racemate of (+)- and (−)-enantiomers. It is metabolized to 0.2% (1). However, animal and in vitro data suggest, that there are differences between the 2 enantiomers with respect to both, anesthetic potency and metabolism (2) Since the separation of the enantiomers is very challenging there are no data about the concentrations of isoflurane enantiomers in humans. In this study we measured the amount of isoflurane enantiomers in the blood of patients undergoing general anesthesia maintained with isoflurane racemate. The amount of the enantiomers were quantified at the end of anesthesia and every day for a period of 8 days after the operation. The study was proven by the Ethik Kommission of the Eberhard Karls university Tubingen

Material and Methods: Enantiomers of Isoflurane were determined using GasChromatography Mass Spectometry (GCMS). For the separation of the recemate a capillary column with a modified cyclodextrinphase was used 41 (25 female, 16 male) patients were included in the study (60 ± 14 yr-old; mean ± SD) after informed consent was obtained. They underwent different operative procedures. The duration of the surgeries was 194 min ± 97. The patients were ventilated via a nonrebreathing circuit Normalventilation was confirmed by capnometry. During surgery, balanced anesthesia was performed with 0.8 ± 0.2 Vol% Blood samples were drawn immediately after the extubation (day 0) and on days 1–8 in 24 patients. 8 patients denied further blood drawing after 5 days ($n = 6$) or 6 days ($n = 2$)

Results: Before the study get started, it was confirmed, that the applied Isoflurane racemate consists of exactly 50%(+) and 50%(−) enantiomers The coefficient of variation (CV) for the different concentrations observed were between 0.06 and 0.2%. The results express the area under the curve of the S(+) racemate [%]. In ASAI–II patients the concentrations of the S(+) enantiomer were between 51–52%. The highest concentration of the S(+) enantiomer was at day 2 In patients with liver diseases ($n = 6$) the S(+)-concentration was also elevated at day 2 (51.66 ± 0.46%, +0.97% in comparison to day 0) In adipose patients the S(+) concentration during the 8 days was +0.355% higher than in normal weight patients The applied Isoflurane concentration had no influence on the enantiomer concentration Also the duration of the operative procedure did not influence the enantiomer distribution.

Conclusion: Our data show that the ratio of 50% S(+) and 50% R(−) enantiomers in the applicated isoflurane racemate is changed in favor to the S(+) enantiomer in man By an overall metabolism of 0.2% a complete exclusion of one enantiomer from being metabolized would only lead to an enrichment of this enantiomer by 0.1%. These data could be explained by different metabolism of the S(+)- and R(−) enantiomers

A.468 Reduction of minimum alveolar concentration of isoflurane by tramadol in comparison with morphine in rats

M.H. de Wolff, P F Wouters. *Dpt of Anesthesiology, Catholic University of Leuven, Herestraat 49, B 3000 Leuven, Belgium*

Background and Goal of Study: Tramadol is a potent analgesic drug with combined opioid (μ effect) and nonopioid (inhibition of NE and 5-HT re-uptake) mechanism of action. The analgesic effect of tramadol is partially antagonised by naloxone, and fully antagonised only by the combination of naloxone and yohimbine ($\alpha 2$ adrenoceptor antagonist) (1). Clinical experience indicates that the administration of tramadol during anesthesia may result in prolonged awakening times. We questioned 1) whether tramadol has the potential to reduce the requirements for anesthetic drugs and 2) which mechanism of action predominates to produce this side effect.

Materials and Methods: Male Whistar rats (250–300 g) were chronically instrumented with a catheter in the internal jugular vein and in the carotid artery. Two days later the study was initiated· Rats were anesthetised with isoflurane, intubated and mechanically ventilated with 100% O_2 Ventilation was adjusted to obtain normal blood gas values. MAC determinations were performed using a standard technique (2), in 9 groups ($n = 10$ for each group). MAC was determined in the following conditions **A)** saline control, **B)** tramadol 10 mg/kg iv, and **C)** morphine 1 mg/kg iv. In addition in all groups the effect of antagonists was studied using: **1)** naloxone 5 μg/kg/min iv and **2)** yohimbine 1 mg/kg iv Data were analysed using two way anova followed by t-test when appropriate ($p < 0.05$)

Results and Discussion:

MAC of isoflurane in rats (mean ± sd)

	Control	Naloxone	Yohimbine
Saline control	1.38 ± 0.16	1.39 ± 0.19	1.37 ± 0.11
Tramadol	1.22 ± 0.18*	1.47 ± 0.13	1.16 ± 0.23*
Morphine	1.17 ± 0.19*	1.38 ± 0.23	1.14 ± 0.06*

* = $p < 0.05$ compared with saline control

Tramadol and morphine both reduce the mac of isoflurane to the same extent Addition of naloxone, but not yohimbine, antagonises this mac reduction

Conclusion: Reduction of anesthetic requirements by tramadol is comparable to morphine both in magnitude and mechanism of action.

A.469 The analgesic potency of xenon and nitrous oxide in humans evaluated by experimental pain

S Petersen-Felix, M Luginbuhl, T Schnider, M Curatolo,
L Arendt-Nielsen[1], A.M. Zbinden *Dept of Anesthesiology and Intensive Care, Inselspital, Berne, Switzerland,* [1]*Center for Sensory-Motor Interaction, University of Aalborg, Denmark*

Background and Goal: The aim of the present study was to compare the analgesic potency of MAC-equivalent concentrations of Xenon (Xe 10, 20, 30 and 40 vol%) and nitrous oxide (N_2O 15, 30, 45 and 60 vol%) in humans using a multi-modal experimental pain testing and assessment technique

Methods: 12 healthy volunteers were tested in a randomised, single blind, cross-over study The following experimental pain tests were used the nociceptive reflex to repeated stimuli, pain tolerance to ischaemia, electrical stimulation, mechanical pressure, and cold The reaction time was also measured Due to nausea and vomiting results for all pain tests could only be evaluated for the two lowest concentrations (Xe 10 and 20 vol%, N_2O 15 and 30 vol%) At 30 vol% Xe and 45 vol% N_2O only results from the nociceptive reflex could be evaluated

Results and Discussion: Xenon and nitrous oxide both increased the threshold for the nociceptive reflex to repeated stimulations, the increased was higher for 30 vol% Xe compared to 45 vol% N_2O – Xe 10 and 20 vol% and N_2O 15 and 30 vol% increased the pain tolerance to ischaemia, and electrical stimulation. The increase in pain tolerance was higher for Xe compared to N_2O at both concentrations for ischaemia and at 20 vol% Xe compared to 30 vol% N_2O for electrical stimulation Xe 10 and 20 vol% and N_2O 15 and 30 vol% slightly increased the pain tolerance to mechanical pressure There was no difference in the increase caused by Xe and N_2O Xe 10 and 20 vol% and N_2O 15 and 30 vol% did not change the reaction to cold, although a slight increase in immersion time (time until hand was withdrawn) was recorded Xe 20 vol% and N_2O 30 vol% increased the reaction time, Xe more than N_2O Of 11 volunteers that could be tested with both Xe and N_2O nausea and/or vomiting was experienced by 9 with Xe and by 6 with N_2O.

Conclusions: The present study shows that xenon and nitrous oxide do not differ in their analgesic profiles Both attenuated pain induced with different modalities in a similar manner Xenon showed an analgesic potency that was at least 1.5 times higher than that of nitrous oxide Both evoked nausea and vomiting in a large number of volunteers.

A.470 Effective concentration$_{50}$ for propofol with 70% xenon *vs* 70% nitrous oxide

S. Schraag[1], M N Schreiber[1], J. Flaschar[1], T Marx[1], G N C Kenny[2],
M. Georgieff[1]. [1]*Dept of Anaesthesiology, University of Ulm, D-89075 Ulm, Germany;* [2]*Department of Anaesthesia, Glasgow Royal Infirmary, UK*

Background and Goal of Study: Xenon has been reported to be a potent and safe anaesthetic [1] and thus supposed to be an alternative to nitrous oxide. We have determined the influence of 70% xenon on the reduction of the effective concentration 50 (EC50) for propofol compared to 70% nitrous oxide

Material and Methods: After obtained institutional ethic's committee approval and written informed consent, 60 female patients undergoing breast surgery were studied They were allocated randomly to receive either 70% xenon (PROP/XE) or 70% nitrous oxide (PROP/N2O) in oxygen. Anaesthesia was induced with propofol with an initial target plasma concentration of 4.5 $\mu g\ ml^{-1}$ using target controlled infusion (TCI) We applied a sequential study design If patients responded to skin incision, the next patient in that group received a target which was 0.1 $\mu g\ ml^{-1}$ higher and if the patient did not respond, 0.1 $\mu g\ ml^{-1}$ lower Response was defined as purposeful movements within 30 seconds after incision. EC50 values were calculated by probit analysis

Results and Discussion: The predicted EC50 for PROP/XE and PROP/N2O was 1.9 $\mu g\ ml^{-1}$ and 3.6 $\mu g\ ml^{-1}$, respectively Thus, the reduction of the predicted EC50 for propofol by xenon was 43% (figure).

Conclusion: We conclude that xenon appears to be 43% more potent compared to nitrous oxide

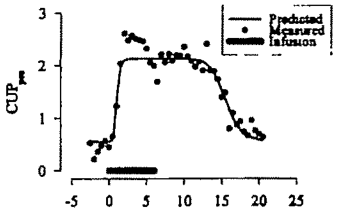
A.471 Quantification of the electroencephalographic effects of propofol using semilinear canonical correlation

P Gambús[1], I.F. Trocóniz[2], T W Schnider[3], C F Minto[4], S L Shafer[5]
Anesthesia Dpt, [1]*Hosp de Viladecans,* [2]*Pharmacy Dpt. Univ. de Navarra, Spain; Anesthesia Dpt,* [3]*Univ Bern, Switzerland, Anesthesia Dpt,* [4]*Univ Sydney, Australia; Anesthesia Dpt,* [5]*Stanford Univ, USA*

Background and Goal of the Study: The EEG is a powerful tool for the measurement of the central effects of hypnotic drugs A new statistical technique, semilinear canonical correlation (SCC), has been used in the analysis of EEG[1]. SCC extracts from the EEG a parameter maximally correlated with biophase concentration of the drug. The goal of this study was to obtain a descriptor of the effects of propofol on the EEG using SCC.

Materials and Methods: We analyzed EEG previously collected under IRB approval from 24 individuals who received propofol at a rate of 0.5 μg/kg/min until 3 seconds of burst suppression appeared in the raw EEG. The result of the EEG processing was a frequency spectrum every 20 sec containing powers in the 10 bins 0.5 Hz to 3 Hz, 3.5 Hz to 6 Hz, ..., 27.5 Hz to 30 Hz. The coefficients γ_1, ..., γ_{10} define an EEG effect measure $E = \Sigma^{10}{}_{i=1}\gamma_i E_i$, herein called the propofol canonical univariate parameter (CUP_{pro}), where Ei is the natural log of the power in the ith frequency bin. The details of the analysis are described in Gregg et al.[1] Using SCC we estimated these ten coefficients in a "learning sample" of 16 individuals. Then the median of these coefficients, were validated in the remaining 8 individuals in whom we also estimated the pharmacodynamic (PD) parameters k_{e0}, IC_{50} and slope of the curve, according to a sigmoid E_{max} model.



Results and Discussion: The graph shows the time course of effect CUP_{pro} in the worst individual according to R^2 criteria (R^2. = 0 77) The median (range) PD parameters were k_{e0}: 0.18 (0 1–0 3), IC_{50}' 1 68 (1 26–2 5), slope: 4.67 (3.4–15.8). R^2. 0 86 (0.77–0.94).

Conclusion: The CUP_{pro} that we obtained is a sensitive measure of the hypnotic effects of propofol reflected in the EEG. Further research is needed to investigate possible effect of covariates on the PD of propofol.

A.472 Assessment of drug-drug interactions in patients receiving postoperative analgesia by intravenous PCA

A. Montes, M M Puig. *Department of Anaesthesiology, Hospital Universitario del Mar, UAB, Barcelona, Spain*

Background & Goal of Study: In the treatment of pain, drug combinations are used to produce effective analgesia while decreasing side effects. The drugs can have an independent action (no interaction) or show synergy or antagonism. The evaluation of an interaction requires pre-designed experiments, sometimes difficult to perform in humans. Our aim was to validate an alternative method to assess drug interactions, using intravenous PCA.

Material & Methods: 101 patients undergoing abdominal histerectomy entered the study Institutional and individual consents were obtained Patients were distributed into groups that received at the time of analgesia request (TAR) one of the following treatments by i v. PCA (randomized, double blind)

Group	Tramadol·Metamizol		Patient Number
	Ratio	Dose	
1	1 0	10 0	21
2	0·1	0 120	21
3	1 1	5 60	20
4	1 0 3	7 5 30	19
5	1 3	2 5.90	20

Tramadol (TR) and Metamizol (MTZ) were administered at fixed ratios based on a relative analgesic potency of 1:12. PCA parameters were: loading dose 10 ml, 2 ml boluses, lockout interval 15 min, maximal dose 50 ml/24 hrs Pain intensity (VAS), number of boluses requested/delivered, and side effects were assessed at TAR and 15 min, 1, 2, 4, 8, 12, 20 and 24 hrs afterwards. Isobolograms, one-way ANOVA, t and χ^2 test were used for statistical evaluation.

Results & Discussion: Groups were comparable regarding demographic data, duration of surgery and TAR. No significant differences between groups at any time point were observed regarding· VAS, % relief, efficacy of the treatment (expressed as the number of patients/group experiencing a $\geq$ 50% pain relief), n° of boluses, or side effects; these results demonstrate that all treatment groups were comparable. The isobolographic analysis of the doses required to produce the same analgesic effect, showed a significant ($P < 0.05$) synergistic interaction between TR and MTZ when combined in a 1.1 ratio (group 3) at the following time points: 8, 12, 20 and 24 hrs No interaction could be demonstrated with the other combinations.

Conclusions: Our study shows that the evaluation of drug interactions can be documented using fixed ratios of the drugs of study, administered by intravenous PCA when a coinciding analgesic end point is achieved.

PAEDIATRIC ANAESTHESIA AND INTENSIVE CARE

A.473 Which method of induction with sevoflurane in children. Incremental or high concentration, with or without nitrous oxide?

M.C Dubois, V. Piat, O Lamblin, I. Murat. *Service d'anesthésie-réanimation, Hôpital d'enfants Armand Trousseau, Paris, France*

Introduction: Induction of anaesthesia is usually performed with incremental concentrations of volatile agent in an O2/N2O mixture in order to reduce the concentration of volatile agent and to speed the induction. Sevoflurane (S) is a non pungent volatile agent and therefore could be administered in O2 alone and with initially high concentration. This study was designed to evaluate these methods of induction

Methods: 65 children aged 20–137 months, ASA I–II, scheduled for tonsillectomy, were prospectively and consecutively allocated to 3 groups (gr) according to the method of induction Premedication was performed 20 min before induction with 0 3 mg/kg rectal midazolam. Gr HC-O2 inhaled 7% of S in O2, gr IC-O2 inhaled incremental concentrations of S in O2 (2%, 4%, 6%, 7% every 5 breaths) and gr HC-N2O inhaled 7% of S in an O2-N2O mixture (50%-50%). Oro-tracheal intubation was performed after insertion of an IV canula, without the use of myorelaxants or opioids Characteristics of induction were recorded by an independent observer and hemodynamic measurements were recorded every minute (Datex). Results are expressed as mean ± SD. Statistical analysis used ANOVA or Chi-square test when appropriate

Results: Demographic data were identical in the 3 gr Loss of eyelash reflex and central miosis occurred sooner in gr HC-N2O than in the 2 other groups, but tracheal intubation was performed at the same time An oropharyngeal canula was inserted before 2 minutes in those patients with obstructive airway No complication such as laryngospasm was observed An increase in SAP and HR was observed between the 2nd and the 4th minute of induction in the 3 groups with no difference between groups

HR initial (bpm)	106 ± 25	103 ± 24	101 ± 19	ns
ΔHR (%)	44 ± 30	40 ± 18	43 ± 28	ns

Conclusion: This study demonstrated that the 3 methods of induction could be used with no severe adverse event, even if the incidence of agitation during induction seems to be more frequent when sevoflurane is administered at high concentration in O2 alone. The addition af N2O allows for more rapid induction with less adverse effects.

A.474 Quality of recovery in children: sevoflurane *vs* propofol

V. Picard, L Dumont, M. Pellegrini, A. Bruce, E. Tassonyi. *Department of Anaesthesiology; Geneva University Hospital, Switzerland*

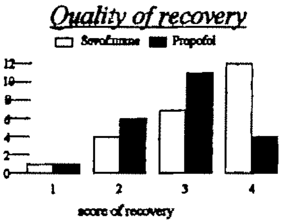
Background: Sevoflurane is a volatile anaesthetic permitting rapid recovery. Propofol-anaesthesia is recognised for it's rapid and clear-headed emergence. This study was designed to compare the emergence and recovery characteristics of sevoflurane and propofol anaesthesia in children scheduled for elective tonsillectomy.

Material and Method: Fifty children aged 3–10, ASA I/II, were randomly assigned in two groups Group P anaesthesia was induced with propofol 3 mg/kg iv and maintained with a propofol infusion 100–250 μg/kg/min. Group S: anaesthesia was induced with 7 vol.% sevoflurane and maintained with 2–3 vol.% sevoflurane. After intubation, ventilation was controlled to maintain normocapnia and all patients received N2O/O2 60/40 vol % for induction and maintenance of anaesthesia. At the end of surgery, infiltration of operative site was done with bupivacaine 0.25 mg/kg for postoperative analgesia The following parameters of emergence were recorded (1) delay from the end of anaesthesia (EA) to extubation, (2) time between the EA and first adequate response to simple command, (3) time spent in the recovery room Five minutes after the arrival in the recovery room, a sedation score was performed as follows **1:** sleepy and barely rousable, **2:** sleepy and easily rousable, **3:** awake and calm **4:** awake and agitated The incidence of nausea, vomiting and excitement was also studied All time data were compared with Mann-Whitney test The incidence of unwanted side-effects was analysed by the Fisher test. A $p < 0.05$ was considered significant

Results and Discussion:

Parameters of emergence

	Sevoflurane	Propofol
(1) Time to extubation (min)	14 ± 3.4	14.7 ± 5.6
(2) Delay to command (min)	21 ± 6	21 ± 7
(3) Time to discharge (min)	45 ± 14	50 ± 15



The quality of recovery shows a predominance of score 4 in the sevoflurane group The incidence of post-operative excitement was significantly higher in the sevoflurane group (46%) than in the propofol group (9%) ($p = 0.008$). The incidence of nausea and vomiting was the same in both groups

Conclusion: Sevoflurane provides an emergence as fast as propofol but with a higher incidence of agitation

A.475 May sevoflurane be preferred to halothane in paediatric ophthalmological anaesthesia?

Erkan Tomatir, Cem Yıldırım[1], Sımay Serın, Habip Atalay, Hakan Erbay, Mustafa Gonüllü *Pamukkale University, Medical Faculty, Dept. of Anaesth. and Ophthalmol [1], Denizli, Turkey*

Background & Goal of Study: It has been suggested that sevoflurane may be a reasonable alternative to halothane in children with respect to hemodynamic stability in induction and emergence from anaesthesia (1). However, the effect of anaesthetics on intraocular pressure must also be taken into consideration for paediatric ophthalmologic anaesthesia There is only one non-comparative study reported that sevoflurane does not significantly change intraocular pressure in children (2). The goal of our study was to evaluate the effect of sevoflurane on Intraocular pressure in children comparing with that of halothane

Materials & Methods: A double blind and randomized study design was used to investigate Fourty ASA class I patients, aged between 1 and 12 years, who would have been planned elective surgery and with no ocular diseases, were divided into two equal groups Sevoflurane or halothane was used incremental doses for induction. Tracheal intubation was performed three minutes after intravenous administration of 0.15 milligrams kg-1 of vecuronium Measurements of intraocular pressure were made using the Perkins hand-held applanation tonometer, at the times of ocular fixation, immediately before and after tracheal intubation For statistical evaluation, ANOVA and t-tests were used. Data are expressed as mean ± standard deviation. $P < 0.05$ was considered significant.

Results & Discussion: Both groups were comparable for demographic data In sevoflurane group, the intraocular pressure values (mmHg) at the times of ocular fixation, immediately before and after tracheal intubation were 14.5 ± 4.1, 10.4 ± 4.6, and 14.1 ± 6.1 respectively, and in halothane group those were 13.2 ± 4.9, 10.6 ± 4.2, and 14.2 ± 5. There were no statistically significant differences between the two groups and within each group

Conclusion: We concluded that the effect of sevoflurane on intraocular pressure in children does not differ from that of halothane and may be used safely in paediatric ophthalmologic anaesthesia.

A.476 Neuromuscular effects of mivacurium in children. Effect of sevoflurane

A Martínez-Tellena, M E. Cano, M M Rodriguez *Depts of Anesthesia and Epidemiology Research Hospital Virgen de las Nieves Granada, Spain*

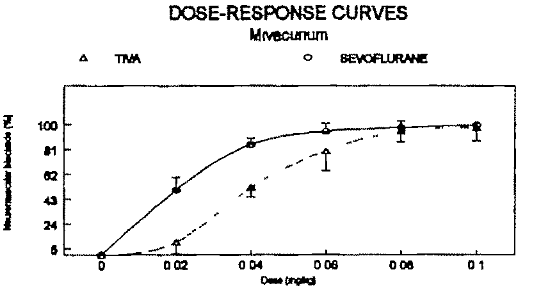
Background & Goal of Study: It is know that the potency of muscle relaxants are increased by volatile anesthetics The purpose of this study was to asses the potency of single dose mivacurium during anesthesia with sevoflurane and total intravenous anesthesia (TIVA)

Material & Methods: After approval by local ethics committee and written informed consent, the neuromuscular effects of mivacurium were evaluated in 60 children during sevoflurane and TIVA anesthesia for short procedures

Following inducción of anesthesia (propofol 2 mg/kg, fentanil 5 μgr/kg) the patients were randomly assignated to receive 1.5 MAC Sevoflurane or TIVA (propofol 8–12 mg/kg/h) and twenty minutes latter to receive one of the following doses of mivacurium (0.02, 0.04, 0.06, 0.08, 0.1 mg/kg) Neuromuscular response was evaluated by measuring the evoked twitch tension of the adductor pollicis muscle in response to supramaximal train of four (TOF) stimulation of the ulnar nerve at the wrist Peak twitch depression was determined following each bolus. The ED_{50} ED_{90} and ED_{95} neuromuscular blocking were calculated from logarithmic regresión análisis Two way analysis of variance was used for statistical análisis In all cases $p < 0.05$ was considered statistically significant

Results & Discussion: The dose response of mivacurium was significantly shifted to the left in sevoflurane group compared with TIVA group. (Fig.) ED_{50}, ED_{90} and ED_{95} were significantly lower in sevoflurane group (Table)

	TIVA	Sevoflurane
ED_{50}	0.040	0.013
ED_{90}	0.078	0.057
ED_{95}	0.085	0.068



Conclusion: Our data show that sevoflurane increase the potency of mivacurium in children undergo short surgical procedures Thus, we thing is necessary, to reduce the dosage

A.477 Endotracheal intubating conditions after cisatracurium in infants and children

I. Waite[1], G Meakin[1], O A. Meretoja[2], R. Perkins[1], T. Taivainen[2], K. Wirtavouri[2], A K. Murphy[1], L Raiha[2] *Department of Anaesthesia, [1]Royal Manchester Children's Hospital, Manchester, UK; Department of Anaesthesia, [2]University of Helsinki Children's Hospital, Helsinki, Finland*

Background: Cisatracurium (Nimbex) is one of the ten stereoisomers which comprise atracurium but is not associated with dose-dependent histamine release in children and adults[1, 2] In this study we determined the intubation conditions and time course of action of cisatracurium in infants and children during N_2O-O_2-halothane or N_2O-O_2-opioid anaesthesia

Methods: With ethics committee approval and informed parental consent, 180 healthy paediatric surgical patients aged 1 month–12 years were studied. Premedication consisted of midazolam 0.2–0.3 mg/kg intranasally or 0.5–0.7 mg/kg orally. Patients were randomised for induction and maintenance of anaesthesia with either N_2O-O_2-halothane (Group H, n = 90) or with N_2O-O_2-thiopentone-fentanyl (Group O, n = 90) Following induction of anaesthesia, cisatracurium 0.15 mg/kg was administered by rapid (5 s) intravenous injection, intubation was started 120 s later and completed within 15 s Intubation conditions were scored using standard criteria: 1 = excellent, 2 = good, 3 = poor, 4 = impossible. Neuromuscular function was monitored using single twitch stimulation at 10 s intervals (Datex Relaxograph).

Results: See table 1 Satisfactory (excellent or good) intubating conditions were obtained in 98% of patients after cisatracurium 0.15 mg/kg; there was no significant difference between the groups Onset time was shorter and recovery time longer in patients anaesthetised with halothane than with opioid. There were no significant changes in heart rate or blood pressure.

Intubation conditions, onset and recovery times

Variable	Group H	Group O
n	90	90
Satis Intubation Conditions No. (%)	88 (98%)	85 (94%)
[95% CI]	[0 92–1 00]	[0 88–0 98]
n	89	89
Time to Max Block (min)	2 6*	3 0
Mean (SD)	(1 0)	(1 5)
n	84	88
Time to 25% Recoery (min)	46 2†	41 1
Mean (SD)	(8 4)	(9 0)

* $P < 0.05$, † $P < 0.001$ (Welch's t-test)

Conclusion: Cisatracurium is a promising non-depolarising neuromuscular blocking drug for use in infants and children. In common with other neuromuscular blocking agents its clinical effects are potentiated by halothane

A.478 An audit of simple dental extractions in children. Chair dental anaesthesia or the laryngeal mask?

A E Slaymaker, A.C. Quinn, R S.E. Edmondson, E.M McAteer. *The General Infirmary at Leeds, UK*

Background and Goal of Study: Fewer anaesthetists are willing to undertake chair dental anaesthesia (CDA)[1]. An alternative technique is the laryngeal mask airway (LMA) with patients in the supine position We have recently converted a CDA list into a LMA list. We compare these two techniques administered by consultant anaesthetists

Materials and Methods: We audited children undergoing simple dental extractions, 50 at the dental hospital using the LMA (group 1), and 50 in general dental practice using CDA (group 2). Induction was with propofol or N_2O, O_2 & sevoflurane. Co-operation at induction was assessed using the Frankl behaviour scale[2]. Ease of surgical access was graded 1–4 In group 1 we documented problems with the LMA. A fibreoptic assessment made of its position and tracheal blood soiling was noted.

Results and Discussion: 96% of group 1 had an iv induction and 74% of group 2 had an inhalational induction. There was no significant difference in the Frankl scale. Surgical access was significantly better in group 1 ($p < 0.05$). In group 1, two patients required intubation, one patient required jaw support throughout and fibreoptic assessment showed two patients with traces of blood in the trachea

Demographic details and times (mins secs)

	Group 1	Group 2
Age m (SD)	8 14 (3.2)	7.9 (2 8) *NS*
Sex M F	28·22	22 28 *NS*
No of Teeth m (SD)	7 24 (3 8)	3 5 (2 5)**
Time 1 m (SD)	163 (25)	40 (11)**
Time 2 m (SD)	5.45 (1 38)	2 16 (0 35)**
Time 3 m (SD)	4 27 (3.12)	1:5 (0 42)**
Time 4 m (SD)	6 23 (2:23)	4·43 (2 16)**
Time 5 m (SD)	62 19 (16·44)	16 10 (4·23)**

NS non significant, $^{*}p < 0.05$, $^{**}p < 0.01$, m (SD)-mean (standard deviation). Times. 1 = total time, 2 = induction to start surgery, 3 = operating, 4 = end surgery to hand over to recovery staff, 5 = start of anaesthesia to discharge home

Conclusion: The LMA technique is a suitable alternative to CDA, but takes longer. This may be because more teeth were extracted, indicating a change in referral practice, but may also reflect a different attitude to day case anaesthesia in the hospital compared to the community.

A.479 Suitability of behavioural items for the assessment of postoperative pain in infants

W. Büttner, W Finke, M Hilleke, A. Münker. *Clinic for Anaesthesiology and Intensive Care Medicine Ruhr-University Bochum, Marienhospital Herne, Germany*

Introduction: The assessment of postoperative analgesic demand in infants is still a problem, since there is no observational system, which has been proven to be economic, valid, sensitive, specific and reliable. We therefore tried to find out prospectively, which of the proposed observational items fulfills these criteria (1–3).

Material and Methods: 13 observational items were included. crying, facial colour, facial expression, forehead's folding, nasolabial foldings, posture of arms, fingers, toes, trunc, legs, motoric restlessness, muscle tone, sweating and state of arousal. They were scaled according to their kind of expression in no, mild or high pronounciation corresponding to 0, 1 and 2 points. During the first postoperative hour all items were scaled in five-minute-intervals by one observer/infant (139 infants, 13 sets, 5 observers). A factor analysis was computed using the 13 different sets and the data of all sets together (principal components; Scree-test, Kaiser-Criterion). A substantial loading on the factor of less than |0 4| at any time excluded the concerned item. This procedure was repeated with the remaining items until any item had a substantial loading of at least |0.4| at any occasion Selectivity of the items were tested using the product-moment-correlation. Finally 5 items built a scoring system. Systemic sensivity and specifity of this set of items were calculated by discriminant analyses Constructive validity was tested using Piritramide ($N = 41$) and Ketamine ($N = 7$) Significance was accepted with $p < 0.05$

Results: Due to insufficient substantial loadings 3 items had to be eliminated. The factor analysis finally resulted in a one-factorial solution with 73% explained variance. The selectivity was highly significant with values between 0.74 and 0 90. For economic reasons 4 items with the least substantial loadings were eliminated (forehead's folding, posture of fingers, posture of toes, posture of arms) 5 remaining items (Crying, facial expression, posture of the trunc, posture of the legs, motoric restlessness) showed a high internal consistency ($\alpha = 0.927^{***}$) The score was reduced in any case using Piritramide or Ketamine. The discriminant analysis resulted in high values for sensitivity (87.9%), specifity (87.1%), positive predictive value (29 3%) and negative predictive value (99.2%).

Conclusion: we identified 5 observational items to be suitable for the assessment of postoperative pain in infants. They build a scoring system which was proven to be economic, sensitive, specific, reliable and valid. Its use in clinical practice and scientific research should be recommended

A.480 Comparison of two paediatric pain scores in urological surgery

J.C Ortiz, J. Mayoral, S. Sabaté, P Baxanas *Anesthesiology Department, Fundació Puigvert, Barcelona, Spain*

Purpose: To compare to pain scoring system in the postoperative urologic surgery in paediatrics.

Material and Methods: Forty-five children (above 13 yr) undergoing urologic surgery were simultaneously assessed using two different pain scoring system The pain scoring systems used were the Objective Pain Score[1] (OPS) and Faces Rating Scale[2] (FRS).

Postoperative pain was evaluated by nurses trained in the paediatric postoperative patients at 0, 30, 60, 120, 180 minutes and every six hours.

Statistical analysis was performed using the χ^2 test and $p < 0.05$ was regarded as significant

Results: Forty-five ASA I patients were included in the study. Demographic data were. age 5.7 ± 3.6 (0.08–12 5 yr.), weight 23.3 ± 13.1 (3.7–59 Kg.), height 110 ± 32 (52–158 cm.). There was a high coincidence between OPS and FRS. The contingency coefficients for OPS and FRS in recovery were: 0.76 ($p < 0.0001$) at 0 minute, 0.79 ($p < 0.0001$) at 30 minutes, 0.66 ($p < 0.0001$) at 60 minutes, 0.81 ($p < 0.0001$) at 120 minutes, 0.76 ($p < 0.0001$) at 180 minutes, 0 63 ($p = 0.003$) at 9 hr., 0.70 ($p < 0.0001$) at 15 hr., and 0.61 ($p = 0.0011$) at 21 hr.

Conclusions: Facial Rating Scale appeared to be similar to Objective Pain Score in paediatric patients undergoing lower abdomen surgery. The FPS was easier to use than OPS and showed a realistic distribution of scores with respect to OPS.

A.481 Clonidine prolongs bupivacaine spinal anaesthesia in newborns

A. Rochette[1], O Raux[1], J. Borry[1], C. Vergnes[2], F. d'Athis[1]. [1] *Dpt. Anesth "A"*; [2] *Dpt. Medical Statistics, Hôpital Lapeyronie, F 34 295, Montpellier, France*

Spinal anesthesia (SA) allows sub umbilical surgery without general anesthesia in newborns, thus avoiding post anesthesia apnea. Plain bupivacaine (B), 1 mg/Kg, provides long enough block in only 50–70% of patients (1). Clonidine (C) prolongs sensitive and motor spinal block in adults (2). In infants, C has been successfully used to lengthen epidural block (3). Yet, C may have sedative effects which must be avoided in newborns. A prospective randomized study was designed to investigate duration, sedative and hemodynamic effects of C-supplemented SA in newborns.

Methods: Infants undergoing elective inguinal hernia repair were enrolled after institutional approval and parental consent. They were allocated to receive via the spinal route either 0 5% plain B: 1 mg/kg or B plus 0.25, 0.50 or 1.0 μg/kg C. The number of patients to be included was calculated from the available data on SA in newborn to reach 50% increase of SA duration and $\beta = 0\ 1$. Nine patients were required in each group Non invasive arterial pressure, heart rate and SpO2 were recorded before SA and every 3 minutes thereafter. Sensitive block extension was assessed by skin pinching at 2, 5 and 10 min. SA duration was defined as the time between injection and hip movement recovery. Sedation and ventilatory status were scanned carefully. Results are presented as median (25–75 percentile). Mann-Whitney-Wilcoxon test was used for comparison between groups. $p < 0.05$ was considered significant.

Results: At the time of surgery, the patients were aged 44 (40–45), 41.5 (39–43), 42 (39–46), 40.5 (37.6–42) weeks post conception, respectively. Anthropometric features, % of ex-premies, extention of SA, occurrence of respiratory problems or anesthetic supplementation were similar in all groups. Decrease in MAP was comparable in all groups: 18 (8–24); 22.5 (12–34); 30 (16–37) and 29 (19–38) % respectively (NS). Durations of the blocks are presented in the table

	B	B + C 0 25	B + C 0 5	B + C 1 0
N	11	18	13	10
Block (min)	67	85	93	103.5
25–75 percentile	(58–82)	(62–108)	(68–110)	(87–113)
p vs control	–	0 12	0 06	0 01

Conclusion: C increases significantly the duration of SA in newborns without deleterious side effects Despite a wide range of individual values, C provides a dose related increase in SA. Further investigation is needed to confirm these data.

A.482 Effects of spinal anaesthesia with pethidine as sole agent, on plasma cortisol and glucose concentrations after lower abdominal surgery in children

C. Mitre, I. Acalovschi. *Department of Anaesthesia and Intensive Care University of Medicine and Pharmacy Cluj-Napoca, Romania*

Background and Goal of Study: The spinal administration of local anaesthetics supress the neuro-endocrine response to surgery (1). In intrathecal administration pethidine has both opioid and local anaesthetic properties (2). We investigated the haemodynamic and stress hormone responses to surgery when spinal anaesthesia was performed with pethidine in comparison with bupivacaine.

Materials and Methods: With Ethical Committee and parents approval, 40 children 3–12 years old were divided into two equal groups, in a randomised, prospective study. According to the body weight $\leq$ 15 kg or $\geq$ 15 kg) the patients received 1.1 mg/kg and 1 mg/kg pethidine 5% (group P) or 0.4 mg/kg and 0 3 mg/kg (group B). A superficial halothane anaesthesia by facial mask in spontaneous ventilation was used for the maintenance of hypnosis. The onset time and duration of sensory block, the blood pressure and heart rate were recorded during the operation. Glucose and cortisol blood levels were measured 1 min before skin incision and at 4 h and 24 h after incision Results were analysed using two way ANOVA. Data were expressed as mean ± SD. $p < 0.05$ was considered significant.

Results and Discussion: No differences were identified between the two groups in terms of demographic variables and haemodynamics. The sensory block was satisfactory in both groups, with the onset faster in group P ($p < 0.001$). In comparison with preoperative values the cortisol levels significantly increased 4 h postoperatively in both groups ($p < 0\ 001$) Glucose levels decreased in both groups but significantly only in group B No significant differences were found between the two groups concerning cortisol and glucose blood levels.

Conclusions: In intrathecal administration pethidine developed a satisfactory sensory block with haemodynamic stability Although in comparison with preincision values, cortisol concentration increased, the hyperglicemic response was suppressed after both agents attesting the local anaesthetic properties of pethidine.

A.483 Long-term epidural anaesthesia with ropivacaine in a small child

B. Gustorff[1], P Lierz[1], K. Hoerauf[1], K. Dieckmann[2], T.H. Knocke[2], H G. Kress[1]. *Dept. of Anaesthesiology & Intensive Care (B)*[1], *Dept of Radiotherapy & Radiobiology*[2], *University of Vienna, Austria*

Background: High plasma levels of bupivacaine occurred after continuous epidural infusion of more than 50 hours [1]. Ropivacaine is assumed to be less toxic compared to equipotent doses of bupivacaine [2]. We now report for the first time the use of ropivacaine for epidural long-term anaesthesia in a small child.

Method: A 21-months-old girl (11 kg body weight) was scheduled for brachytherapy of a vaginal rhabdomyosarcoma. Radiation was performed via a painful applicator filling the whole vaginal cavity After written parents' consent a continuous infusion of ropivacaine 0.5% was initiated at a rate of 2 5 ml h^{-1} (1 14 $mg{\cdot}kg^{-1}{\cdot}h^{-1}$) via an epidural G 23 catheter (L4/5) with optional bolus (3 ml every 30 minutes) to achieve the required analgesia and partial immobilisation. After 51.5 h ropivacaine 0 75% was administered for a 26.5 h period at the same rate but with a 4 ml bolus option Sensory block, motor block, heart rate and peripheral oxygen saturation were monitored. Blood samples for the determination of the ropivacaine plasma level were taken after 22 and 70 hours.

Results and Discussion: During the entire treatment period (78 h) no respiratory, cardiovascular or toxic side effects occurred Satisfying anaesthesia including the intended partial motor block was only obtained by an increasing number of boli and augmentation of the concentration (3rd day). Nevertheless sensory block did never exceed the T8 level The average amount of ropivacaine rose from 1.4 $mg{\cdot}kg^{-1}{\cdot}h^{-1}$ (1st day) to 1.5 $mg{\cdot}kg^{-1}\ h^{-1}$ (2nd day) and 3 $mg\ kg^{-1}{\cdot}h^{-1}$ (3rd day) suggesting tachyphylaxis. Surprisingly the plasma levels (1 8 $\mu g{\cdot}ml^{-1}$ and 1 5 $\mu g{\cdot}ml^{-1}$ after 22 h respectively 70 h) even decreased.

Conclusion: Ropivacaine 0.5% and even 0.75% proved to be effective and safe during brachytherapy for continuous epidural long-term anaesthesia in a 21-months-old child over 78 hours. Surprisingly, the plasma level of ropivacaine decreased despite a more than two-fold increase in dosage during 70 hours Since plasma levels of 4 $\mu g{\cdot}ml^{-1}$ in adults are regarded as toxic threshold concentration, these data confirm the safety of ropivacaine even with increasing doses due to tachyphylaxis. In contrast, bupivacaine was reported to accumulate in adults [1]. Enzyme induction and increased metabolism might be an explanation in this child.

A.484 Technical aspects of paediatric epidural catheter insertion: a prospective study of 338 cases

F Roelants, H. Waterloos, L J Van Obbergh, F. Singelyn, J.M. Gouverneur, F. Veyckemans. *Dept Anesthesiology, Clin Univ St Luc, Ave Hippocrate 10-1821 1200 Brussels, Belgium*

Introduction: Since 1986, epidural analgesia is routinely used in our hospital to provide postoperative analgesia for children undergoing major surgery. This prospective study was undertaken to evaluate the incidence of technical problems encountered at the time of insertion of the EC.

Population & Methods: All EC inserted in children <15 years-old from Oct 1995 to Oct 1997 were included in the study. Demographic and technical data were collected on a special data sheet. Epidural analgesia was used only for major surgery and with oral consent of the parents. All EC were inserted under general anaesthesia A 18 or 19 G (if <12 kg) Tuohy needle was used to insert the EC using the median approach and the loss of resistance to "saline + a bubble of air technique" (1). The epidural space was punctured at the dermatomal level involved by surgery and the EC was threaded only of few cm into the epidural space. Chi-square was used to assess statistical significant

Results: A total of 338 EC were inserted· 176 and 162 EC were inserted through 18 and 19G needles, respectively. Their distribution according to level of puncture and body weight (bw) is shown in the table, as well as the number of cases in which the EC could be inserted at 1st attempt.

BW, kg	<5	5 1–10	10 1–20	20 1–30	>30
(n)	(23)	(88)	(120)	(74)	(33)
<T10	6	16	29	19	11
T10-L2	11	31	22	15	6
>L2	6	41	69	40	16
1st attempt	11	62	91	61	24
IES (%)	9 (39.1)	17 (19 3)	25 (2)	7 (9 4)	4 (12.1)
TEC (%)	4 (17 3)	11 (12 5)	4 (3 3)	2 (2 7)	3 (9)

As shown in the table, the most often reported technical difficulties were problems identifying the epidural space (IES) or threading the EC (TEC) Both were significantly (IES p = 0.018) (TEC p = 0.014) more frequent in children less than 10 kg No morbidity was associated with the insertion of these EC; only one dural tap occurred, in the 10.1–20 kg group

Conclusion: In our series, the incidence of technical complications at the time of EC insertion was low: 74% of EC were inserted at 1st attempt However, both identification of the epidural space and the insertion of the EC were more difficult in children <10 kg Our incidence of dural taps (0.3%) was much lower than reported by Dalens (1.8%) using similar needles but loss of resistance to saline or air (2).

A.485 How reliable are oscillometric blood pressure monitors in neonates and infants?

B. Oldörp, S. Mieke[1], G Papadopoulos[2]. *Univ Dept of Anesthesiology and operative Intensive Care, Benjamin Franklin Hospital, Berlin;* [1] *Physikalisch-Technische Bundesanstalt (PTB), Berlin, Germany;* [2] *Dept. of Anesthesiology, University of Ioannina, Greece*

Background and Goal of Study: Non-invasive blood pressure measurements with automated oscillometric devices is considered to be safe and reliable. The objective of this study was to evaluate the performance of four blood pressure monitors, which are frequently used with neonates and infants.

Materials and Methods: A simulator[1] developed by the PTB, which allows the synchronized playback of real data records, was used for the assessment of the reproducibility and for the comparison of the oscillometric devices (SpaceLabs, Hewlett-Packard, S&W Medico and Critikon). The signals used for the simulation were obtained from 24 preterm and term neonates and infants, aged between 6 and 93 days and weighing between 902 g and 3500 g. 24 oscillometric signals were used for the simulation (one from each patient). Each signal was repeated 20 times for the systolic, diastolic and mean arterial pressure.

Results and Discussion: The reproducibility-coefficients were between 8 mmHg and 18 mmHg. Blood pressure fluctuations in (critically ill) neonates need to be observed accurately in the range of 5–10 mmHg (estimated range of autoregulation)[2], which is precluded by the performance of the oscillometric monitors. The test of agreement by Bland and Altman[3] generated 'limits of agreement' (consistent with ± 2 SD around the mean differences), which were invariably high for each monitor (average of 20 mmHg).

Conclusions: Single blood pressure measurements with the four oscillometric devices cannot be considered as reliable. These monitors, revealing a significant lack of (clinically satisfactory) agreement, should be regarded as different methods of blood pressure measurement, especially since the oscillometric method is not standardized and the algorithms employed to determine the blood pressure vary with the manufacturers and are not disclosed by them.

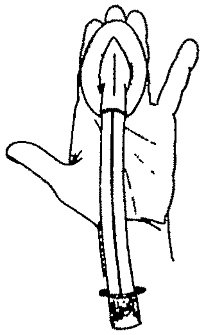
A.486 An alternative method to determine the size of laryngeal mask airway in children

L. Gallart, A. Mases, J A. Martinez-Pérez, A Montes, S. Fernández-Galinski, M M. Puig. *Servei d'Anestesiologia i Reanimació, Hospital Universitari del Mar, Barcelona, Spain*

Background & Goal of Study: The size of laryngeal mask airway (LMA) in paediatric anaesthesia is usually determined according to the weight of the patient[1]. However, in some cases this parameter cannot be obtained. We propose a new method, easy and applicable at the bed-side. To validate this procedure, the sizes of LMA determined with this method are compared with the sizes according to the patient's weight

Materials & Methods: 117 paediatric patients, aged from one month to 14 years and without anatomical and/or nutritional disorders, entered the study. In every patient, the hand was opened separating the first and the 5th fingers, keeping the 2nd, 3rd and 4th fingers extended and together Different LMA sizes, inflated with the maximal standard volumes[1], were applied to the ventral side of the hand, keeping the widest part of the LMA on line with the widest part of the three fingers together The LMA best fitting these three fingers was chosen (figure). For every patient, this size was compared with the suggested size of the LMA considering the patient's weight. Kappa coefficient (κ) was used to evaluate the agreement between both methods.



Results & Discussion: The table shows the number of patients for every possible combination of MLA sizes, determined by patients' weight and by the fingers' method. Italic numbers indicate the patients (100 children, 85%) in which the size of the LMA coincided with both methods.

MLA Size		Size according to Weight				No patients
		1	2	2 5	3	
Size according to Figure	1	*9*	3	0	0	12
	2	1	*45*	1	0	47
	2 5	0	8	*29*	3	40
	3	0	0	1	*17*	18
No. patients		10	56	31	20	117

κ coefficient was 0.85, showing an "excellent agreement" between both measurements.[2]

Conclusions: This alternative method to determine LMA size appears to be useful when compared to the current "Gold Standard" (patient's weight). At present, we are comparing both methods in children undergoing general anesthesia, by assessing gas leak during mechanical ventilation.

A.487 Sedation for paediatric endoscopic procedures: comparison of two techniques

C.E. Lesmes, H Hager[1], E Nussenson[2], Y. Katz. *Department of Anesthesiology and the Pediatric Gastroenterology*[1]; *Gastroenterology Unit*[2], *Ha'Emek Medical Center, Afula, Israel*

Background and Goal: Esophagogastroscopy and colonoscopy are a very useful diagnostic and therapeutic, yet invasive, procedure in the pediatric population Concerns regarding their performance include the need for sedation and analgesia, quality of conditions and recovery from the sedative agents. Most of these procedures are undertaken in an ambulatory environment thus emphasizing the importance of a swift recovery in the absence of side effects. Our work compares two of the techniques in use at our institution in the issues of safety, efficacy and suitability.

Materials and Methods: 100 children admitted to our facility were randomly assigned to two groups: group A received sedation with an intravenous Propofol infusion regime; group B received sedation with a combination of Meperidine and Midazolam intravenous titrated injections. Both groups were prepared similarly regarding fasting orders, monitoring and oxygen supplementation during the procedure. Data recorded included demographics, medication doses, procedure time, quality of procedure according to a score devised by Squires, Morriss et al.[1] and recovery time. Any complication or side effect was also recorded.

Results: Group A included 53 children aged 9 mo. to 12 years (median: 3 yrs), weights 7.2 to 35 kgs. (mean weight: 11.4 kgs.), a Propofol infusion started at a loading dose of 3 mgs /kg. followed by 6 mgs./kg./hr. was given using an automatic syringe pump (Graseby 3400). Procedure times ranged from 17 to 85 mins. (mean time 22 minutes), adequacy of conditions rated a mean of 1.2 (median 1) recovery times ranged from 7 to 23 mins. with a median of 16 minutes Side effects included transient mild hypoxemia (no less than spO2 89% for no more than 15 seconds) and a tendency to bradycardia (heart rate never less than 90 bpm). Group B comprised 47 children aged 2 to 14 years (median. 5 yrs), weights 11 to 50 kgs. (mean weight 27 kgs.), Meperidine and Midazolam were given intravenously in alternating, titrated doses up to 1 5 mgs /kg and 0.2 mgs./kg respectively Procedure times were 8 to 23 minutes (mean time 11 minutes), adequacy of conditions scored a mean of 1.6 (median 2), recovery times ranged 31 to 112 mins with a median of 65 minutes. Side effects included transient mild hypoxemia similar as that for group A and an increased rate of nausea and drowsiness.

Conclusion: The Propofol infusion regime demonstrated a better profile with improved adequacy of conditions (1 2 vs 1.6, $p < 0.05$) of procedure, faster recovery times (16 vs 65 minutes) and less nausea and drowsiness (2 vs 12). Procedure times were longer in group A probably due to more colonoscopy patients included in this group but this did not affect recovery times. Propofol infusion is a better choice for sedation in children undergoing ambulatory esophagogastroscopy or colonoscopy

A.488 Is cooling essential in paediatric cardiac surgery? Clinical outcome after high-flow normothermic cardiopulmonary bypass

A B Lal, A F Corno, A Valori, D.N. Robinson. *Depts of Anaes and Paediatric Cardiac Surgery, HCI International Medical Centre, Beardmore Street, Clydebank G81 4HX, Scotland*

Background: Hypothermia was first introduced in cardiopulmonary bypass (CPB) as a means of neuro-protection It is not physiological, causes impaired membrane function, ion pump inactivation, unfolding and denaturation of proteins, activation of Na-K ATPase, Ca ATPase, and impairs membrane function It worsens bleeding and pulm. compliance, with uncertain reduced risk of cerebral injury (1) It contributes marginally to improved myocardial protection over electromechanical quiescence (2)

Method: 70 consecutive surgical procedures were:

Simple· VSD (12), ASD (9), ASD + PS (1) Total = 22

Complex: TOF (6), AVSD (6), PA + VSD (5), Complex VSD (4), Mult. VSDs + RVOTO (4), PAPVC (4), MVReg (3), TGA (3), Tric Atr. (3), Ao Reg (2), DORV (2), PA + Intact V S (2), Conduit Obstruction (2), LVOTO (1), TAPVC (1). Total = 48

All surgery was performed on warm bypass with active warming to 37°C, flow rate of 3–3.5 $L/m^2/min$ Myocardial protection was with cold intermittent blood cardioplegia, and the haematocrit was maintained at 30%

Age 3 yrs 8/12 (2 mos–26 yrs) (median ((range))

Weight 11.95 Kg (3.8–58 Kg).

Ao. CC time 30′ (0–165′), CPBP time 94′ (28′–504′)

Results: *Excluding 4 patients who died.*

Time to.	Spont breathing	Extubation
<3 hrs	54 pts (81 81%)	28 pts (42 42%)
<24 hrs	85 pts (98 48%)	63 pts (95 45%)
>24 hrs	1 pt (1 51%)	3 pts (4 54%)

Use of Dobutamine 0–5 γ/Kg/min, 29 pts (43.9%)
5–10 γ/Kg/min, 6 pts (9.09%)
>10 γ/Kg/min, 1 pt (1 5%)
Other inotropes 16 pts (24.24%) Duration 1 day (3 h–7 days)
Periph. Temp. (6 hrs postop)· 36° C. (31–37.5°C)
Blood loss (Ir 6 hrs postop)· 10 ml/Kg (2 96–43 7)
$NaHCO_3$: 6 pts (9.09%)
Diuresis in 24 hrs (ml/Kg/hr)· 2.38 (0.9–6 19)
ICU stay: 1 day (1–13) HOSP. stay: 7 days (3–39)

Conclusion: We believe that *'warm body-cold heart'* surgery is an excellent technique with high flow CPB. Our patients had minimal bleeding, low use of inotropes, good renal & respiratory function and peripheral perfusion Although we do not have a long term neuropsychological evaluation, none of our patients developed major neurological deficits

A.489 Low dose oral ketamine augments midazolam premedication in paediatric patients

W. Funk, T. Riedl, J Schickendantz, K Taeger. *Department for Anaesthesiology University of Regensburg, Germany*

Background: Anxiolysis and sedation with oral midazolam are common practice in pediatric anaesthesia However, good or excellent results are seen in only 60–80% of cases (1) In our own patients presenting for dental repair, success rate is even lower (50%). For this reason, we asked in a prospective, randomized trial, if the addition of a low dose (2) of oral ketamine (MIKE: Ketamin 3 mg/kg, midazolam 0 5 mg/kg) results in a better premedication as compared to oral midazolam alone (MIDA, 0 5 mg/kg). We included 80 children (mean age 5 7 y, range 2–10), who underwent dental repair or strabism correction

Material and Methods: Upon approval by the local ethics committee and informed parental consent the children (ASA 1/11) were randomised into one of the study arms 20 min after oral premedication in the ward, the child's condition in the induction room was evaluated assigning 1 to 4 points to the quality of anxiolysis, sedation, behaviour at separation from parent and during venipuncture (with EMLA) On the 1st and 7th postoperative day, parents were interviewed for changes in behavior (eating, sleep, dreams, toilet training), recollection and satisfaction using a standardized questionnaire Evaluations used ANOVA and chi-square statistics

Results: Groups were similar with regard to age, sex, weight, intervention and duration of anaesthesia The results prior to Induction are given in the table: ("Success": Number of children with score 3 or 4, (). %success)

	Success Sedation	Success Anxiolysis	Success Separation	Puncture painless
MI	22/38	29/38	26/38	34/38
DA	(58)	(76)	(68)	(89)
MI	27/39	37/39	35/39	38/39
KE	(69)	(95)	(90)	(97)
	n s	p < 0 05	p < 0 05	n s

Apart from rare nystagm, no significant side effects (oxygen desaturation, hypersalivation, psychotic symptoms) were observed In the recovery room, no differences were found regarding sedation or time of possible discharge (ALDRETE Score ≥ 9). After 1 week, parents reported nightmares (MIDA 2, MIKE 2) restless sleep (6/9) or negative remembering (8/5). No substancial or continuing disturbances of behaviour or development were reported

Conclusion: Better anxiolysis and separation with ketamin plus midazolam were observed even in awake children (sedation not successful according to the preset criteria). The Increased success rate is of clinical significance The improvement was reflected in a lower stress factor for the inducing anaesthesist as evaluated by a VAS (1–10) (MIDA 2.8, MIKE 2.1, p = 0 1). The combination of both drugs in glucose sirup (pH 4 5 app) is chemically stable for 8 weeks (own data, remaining activity > 90% for both, HPLC)

A.490 Efficacy and tolerability of tropisetron in the prevention of nausea and vomiting in children undergoing tonsillectomy and/or adenoidectomy

C Diliber, M Weiss, A. Ch Gerber *Department of Anaesthesia, University Children's Hospital Zurich, Switzerland*

Background and Goal of the Study: Nausea and vomiting are common problems after tonsillectomy[1]. Tropisetron, a new, long-acting 5HT3 antagonist has been found to be effective in preventing postoperative nausea and vomiting in adults[2] Its postoperative antiemetic effect in children is not yet well documented We studied the efficacy and tolerability of a single intravenous dose of tropisetron in preventing nausea and vomiting after tonsillectomy and/or adenoidectomy in children

Materials and Methods: With Hospital Ethics Committee approval and parental written informed consent we studied 98 children aged 2–12 years, ASA physical status I or II undergoing tonsillectomy and/or adenoidectomy in a prospective, randomised, double-blind, placebo-controlled study. Inhalational anaesthesia with Sevoflurane in N_2O/O_2 was performed After intubation Tropisetron 0.1 mg/kg (max 2.0 mg) or placebo was administered intravenously. Emetic episodes, need for rescue antiemetic treatment and analgesics were recorded for 24 hours after surgery Vital signs and sedation-scores were assessed in the first 4 postoperative hours Patient data were analysed using t-test and chi-square tests ($p = 0.05$).

Results and Discussion:

Vomiting episodes	Control	Tropisetron	p
None	17 (34 7%)	32 (65 3%)	<0 05
≥3	11 (22 4%)	5 (10 2%)	<0 0004
Need for antiemetics	14 (28 6%)	10 (10 4%)	<0 025

The only significant difference between the study groups was a slight predominance of males in the control group No difference could be shown between the groups for vital signs and sedation-scores Tropisetron significantly reduced postoperative vomiting and need for antiemetic medication during 24 hours No significant adverse effects of the study medication could be detected

Conclusion: One single intravenous dose of Tropisetron administered before surgery effectively reduces postoperative vomiting during 24 hours in children undergoing tonsillectomy/adenoidectomy

This research was supported by Novartis Pharma, Switzerland

A.491 Intrathecal morphine for pain control in adolescents after scoliosis surgery

M.J. Colomina, C. Godet, A Vivó, J. Bagó, F Pellisé, C Villanueva
Hospital Traumatología Vall d'Hebron Barcelona, Spain

Background & Goal of Study: Efficacy and safety in the control of postoperative analgesia is a difficult combination to reach in the pediatric population. The goal of our study is to evaluate the efficacy of low dose intrathecal morphine (0.01 mg kg^{-1}) and secondary effects in adolescent patients undergoing surgery for spinal deformities.

Material and Method: Between Feb-94 and July-97, 101 patients were prospectively enclosed The group was formed by 28 males and 73 females Age ranged between 11–19 years, the weight from 27–84 kg and the height 128–187 cm. In 73 cases was idiopathic scoliosis and 28 cases secondary scoliosis. Upon concluding spinal arthrodesis, the surgeon, under direct vision introduced the needle in L3–L4 or L4–L5 spaces The dose administered was 0.01 $\mathrm{mg.kg}^{-1}$, not exceeding 0 5 mg in total. To evaluate the results we gathered the following parameters: Time of opiate-dependent analgesia, the type of analgesic needed to pain control, the appearance of secondary effects, and the necessity of naloxone to treat it

Results & Discussion: The time of opiate-dependent analgesia ranged between 1 3 and 64 hours (23.1 ± 12 3). In 88.6% of cases, analgesia lasted more than 12 h. and in 40.4% exceeded 24 h Only 3 patients (2 9%) needed parenteral morphine; 64 (63.3%) required NSAID and 34 (33.7%) didn't demand any type of analgesic. Not one patient presented respiratory depression, somnolence, nor pruritus. 19 patients (18 8%) had nausea and 28 (27.7%), vomiting. Naloxone wasn't necessary in any case In multiple regression analysis there was no relation between time of analgesia and weight, height, type of scoliosis or total dose of intrathecal morphine Our results compare favorably with others studies[1, 2] that reported 18–36 h. Of analgesia.

Conclusions: Intrathecal morphine is safe and effective for the control of postoperative pain after surgery of spinal deformities Pain could be controlled by standard analgesics and parenteral opiates are avoided.

A.492 Biblocks in congenital club foot surgery

E Civran, M. Grazzini, D. Carren, G Manani[1], G.P. Giron. *Istituto di Anestesia e Rianimazione, Università di Padova; [1] Cattedrà di Anestesia Generale e Speciale Odontostomatologica, Università di Padova, Italy*

In most surgical procedures in paediatric orthopaedic practice regarding the lower limbs, regional anaesthesia is recognized as an effective method of providing analgesia in children The aim of this study is to show our experience in relation to regional anaesthesia in newborns and in children under six years of age, who should undergo surgery for the lengthening of Achille's tendon in club foot

Material and Methods: The present study was conducted, after obtaining parents' consent, on 32 children under six years of age with club foot who were divided into two groups· 21 children under 24 months (10 5 ± 1.7 ms) and 11 children over 2 years of age (4.6 plusmn; 1.0 ys), ASA I o II. Sleeping phase was obtained with intramuscular ketamine 7–10 mg/Kg, intramuscular atropine 0.02 mg/Kg and intravenous diazepam 0.2 mg/Kg. To guarantee the immobilization of the child during the operation, isolated doses of intravenous ketamine or diazepam 0.1 mg/Kg were administered. The performance of the biblocks (femoral nerve block and sciatic nerve block) (1) was obtained using not traumatic needles 20–21 G, 3.5 cm, connected to a neurostimulator Medival, set to 0 5–1 mA and 3 Hz (2). Isobaric Bupivacaine 0 25% was used as local anaesthetic and the total dose was of 2 5 mg/Kg.

Results and Discussion: All the 32 patients, under six years of age, who underwent surgery for congenital club foot were subjected to biblocks and the perioperative analgesia was excellent; all blocks were successful at the first attempt. Biblock technique guaranteed analgesia; furthermore it did not cause a motor block and all the discomforts related to it. A subarachnoid block or a general block were never necessary. There were no collateral effects due to the local anaesthetic. Postoperative analgesia was excellent. The analgesics was usually administered 12 hours after surgery. The oral hydration and the feeding were respectively begun 3 hours and 6 hours after the end of the operation.

Conclusion: B blocks in paediatric orthopaedic surgery can be considered a safe and good alternative to central blocks and general anaesthesia as it guarantees a good perioperative analgesia

A.493 Infraclavicular block in children: is it an alternative to axillary block?

Robert J. Steur. *Kinderspital Wildermeth 2502 Biel, Switzerland*

Introduction: In October 1995 we introduced the infraclavicular block as an alternative for the axillary block. Our success rate was around 85%, comparable with the figures in the literature. The success rate for the supraclavicular block was around 97%. We looked for an alternative for the axillary block, something as good as the supraclavicular block, but without the dangers and complications of this block. We might have found it in the infraclavicular block

Technique: The patient is supine The arm may be in every position, as long as it comfortable for the patient The landmarks are clavicle, interscalene groove and the fold between arm and thorax. One draws a line from the interscalene groove to the end of the fold Halfway this line is the injection point. The needle must be introduced perpendicular to all planes The needle length has to be chosen to the size of the patient We use isolated needles with a nerve stimulator to find the nerves. In children one has to use a nerve stimulator for every peripheral block in children, because they will not tell you when they feel paraesthesia. We search for movements in the hand, forearm or shoulder/upperarm, or in the range of the ulnar, median and radial nerve.

Indications: All operations below the shoulder, with or without a bloodless field.

Results:

Year	Number	Comb anest.	Sedation	<2 years	<7 years	≥7
1995	29	8		1	5	23
1996	128	38	9	7	19	102
1997	65	13	5	6	12	47
	222	59	14	14	36	172

We had 9 partial blocks (failure rate 4%). This is much less than the figures of the axillary block This reaches the range of the figures of the supraclavicular block. We found a good alternative for the axillary block In fact is it a more universe block, while it can be performed with the arm in every for the patient comfortable position. The duration of the block varies.

Complications: We have had 1 clinical not significant pneumothorax. This was in the learning phase of this block.

Conclusion: The infraclavicular brachial plexus block is a good alternative to the axillary block, with a higher success rate It is a very useful block in children, because it is to perform independent of the position of the arm *and* the head.

A.494 Caudal ropivacaine (0.25%) and bupivacaine for postoperative pain relief in children

D. Ozcengiz, H. Özbek, H. Unlugenç, G. Işık. *University of Çukurova, Adana, Turkey*

Background & Goal of Study: Ropivacaine is a new local anaesthetic agent and very similar to bupivacaine, structurally (1, 2). We aimed to compare the effects of caudal ropivacaine and bupivacaine on postoperative analgesia in children.

Materials & Methods: The study was performed in thirty four children, aged between 1 and 9, undergoing for elective inguinal hernia repaired after approval by the ethical committee. No premedication and analgesic drug were applied Systolic arterial pressure (SAP), diastolic arterial pressure (DAP), peripheral O_2 saturation (SpO_2) and ECG were observed continuously in the operation room. Anaesthesia was obtained with halothane

(3%) and N_2O (67%) in oxygen and maintained with halothane (1–2%) and N_2O (67%) in oxygen Succinylcholine was administrated in patient who needed endotracheal intubation or muscle relaxation. At the end of the operation, all patients were taken in left lateral position and sterilized The patients were divided into two groups, randomly. Patients in group I (n = 17) received 0.5 ml/kg bupivacaine (0 25%) and patients in group II (n = 17) were applied 0 5 ml/kg ropivacaine (0 25%), caudally All patients were taken in postoperative recovery room following caudal application and turning off the anaesthesia The level of analgesia was assessed using paediatric objective pain score at 15th min, 1st, 2nd, 3rd and 4th hours postoperatively Bromage's modified motor block scale was used for the assessment of motor block

Results & Discussion: There was no difference between groups in weight and age POPS was not any differences between the groups at 15th min, 1st, 2nd, 3rd and 4th hours postoperatively POPS decreased at 1st and 2nd hours compared with 15th min value, however, there was no difference at 3rd and 4th hours. POPS was not higher than 5 point in any patients. Motor block was not seen. SAP, DAP and HR were the same in both groups No side effects related to local anaesthetic were observed in our patients

Conclusions: We concluded that ropivacaine (0 25%) is as efficacious as bupivacaine (0 25%) in producing postoperative analgesia for inguinal hernia

A.495 Comparison of postoperative analgesia in children after continuous I.v. infusion of morphine or nalbuphine through a single-use infuser (Baxter)

D. Velegrakis, Chr Loizou M Papageorgiou, A Malissiova,
A. Avgerinopoulou. *Anaesth. Depart. of Children's hospital of Athens, Greece; "P & A Kynakou "*

Background and Goal of Study: With this study we wanted to evaluate the efficiency of morphine or nalbuphine through continuous infusion in post-operative pain control during the 24-hours after Intervention. For this purpose we have used the Baxter Travenol Infusor [1]

Materials and Methods: In this study we included 60 children undergoing major orthopaedic surgery (duration 3–5 hours). For the Induction and maintenance of anaesthesia and the intraoperative analgesia we followed the same protocol for all children

At the end of the surgery and in the recovery room the children were assigned to two groups. Group A (n = 30) received I.V morphine 0.1 mg/kg as a bolus dose and was connected with NCA through an independent vein The elastic balloon was filled with morphine sulfate 20 μg/kg/h [2] diluted in 50 mls of D/5% with a flow of 2 ml/h. Group B (n = 30) received a bolus dose of 0 2 mg/kg of nalbuphine and the elastic balloon was filled with 0 05/kg/h nalbuphine [3] diluted in the same way as above.

Tropisetron (0 2 mg/kg-total dose 5 mg) was given IV to all children because of its antiemetic action.

Every six hours additional paracetamol (15 mg/kg) or proparacetamol (30 mg/kg) was given per os or I V

Every two hours we assessed the following parameters. pain scores, arterial oxygen saturation, consciousness level, respiratory rate, nausea and vomiting, urine retention. pruritus

Parametric data were analyzed using x-square test.

Results and Discussion: There were no significant statistical differences between the two groups. A mild to moderate pain was observed in two children of group A and three children of group B. Urine retention was observed in two children of group A and one of Group B Pruritus appeared in one child of Group A and in one of Group B

Constant infusion of both medicaments with a light, small device ensures constant plasma concentration, good analgesia and minimal side-effects

Conclusion: We recommend both methods as safe and effective for the control of post-operative pain

A.496 Does propofol protect against postoperative vomiting after tonsillectomy in children?

A. Malissiova, E. Kalliardou, S. Mitsiou, P Matsota, M. Papageorgiou.
Anaesthesiology Dept , P&A Kirlakou Children's Hospital, Athens, Greece

Background & Goal of Study: The goal of this study was to evaluate the antiemetic properties of propofol as a drug of induction in anaesthesia in tonsillectomies in children. We compared it to pentothal, a drug widely used by our practitioners for the same reason This study is part of a wider investigation still conducted in our department concerning postoperative nausea and vomiting in all paediatric surgical patients

Materials & Methods: 93 healthy children ASA I–II, aged 2–12, were randomly assigned to receive either propofol 2 5 mg/Kg or pentothal 5 mg/Kg as an induction factor All children were orally premedicated with diazepam 2 mg/Kg In both groups anaesthesia was maintained with oxygen-nitrous oxide and fentanyl 2 γ/Kg The mean age of the propofol group (A), (n = 49) was 6 44 with SD 3.04 and of pentothal group (B), (n = 44) was 5.68 with SD 2 82. The mean time of operation was in (A) group 19 21 min, SD 2 4 and in (B) group 21 45, SD 1.97. We used no antiemetic drugs Gastric contents were strictly aspirated in all patients after beginning and before the end of anaesthesia.

Paracetamol suppositories 30 mg/Kg were administered in all children while being in the recovery room

Results & Discussion: Vomiting was recorded for 24 h postoperatively by nursing stuff while subjects were in hospital and by parents after discharge from hospital. We found that 17 children of the (A) group and 19 from the (B) group vomited once or more times after surgery The difference between the two groups using the X^2 test was not statistically significant, $p > 0$ 05 Rescue antiemetics were administered when patients vomited more than twice This happened to two children of each group

Conclusions: We concluded that propofol as an induction factor is not an effective means of preventing vomiting after tonsillectomy in children compared to pentothal

A.497 Incidence and therapy of midazolam-induced hiccups in paediatric anaesthesia

P Marhofer, C. Glaser, C.G Krenn, C Grabner, M Semsroth *Dept. of Anesthesiology and General Intensive Care, Univ of Vienna, A-1090 Vienna, Austria*

Background: Rectal midazolam premedication is the golden standard in pediatric anesthesia (1) One of the side effects of this technique are hiccups, which can cause aspiration during mask-induction for general anesthesia (2), aspiration before or during rapid sequence intubation in emergency surgery or movements during diagnostic examinations (i e computertomography) Aetiology, Incidence and therapy of these hiccups are unknown. The goal of our study was to investigate a possible therapy of midazolam-induced hiccups by intranasal chlormethyl-spray application, which causes an intranasal cold stimulation, and a possible age or dose dependence of midazolam-induced hiccups.

Methods: After institutional approval and informed consent 100 children (ASA I, 3–15 kg) undergoing elective minor surgery were enrolled for the study. Group A was rectal premedicated with 0.5 mg/kg midazolam, Group B was rectal premedicated with 1 mg/kg midazolam If the children had hiccups during the following 20 min, we treated them with two short intranasal applications of chlormethyl-spray (Chlormethyl Dr Henning Spray™). The time from spray application to the possible interruption of the hiccups was measured All results were expressed as mean ± SD Statistical analysis was performed by ANOVA and Student's t-test. A $p < 0$ 05 was considered significant.

Results: We found 22% hiccups in group A and 26% in group B (n s) Time from rectal midazolam premedication to the first hiccup was 9 ± 5 min in group A and 12 ± 8 min in group B (n s). The intranasal chlormethyl-spray application (24 cases) was successful in 100% in both groups. We observed no side effects of our therapy Time from chlormethyl-spray application to interruption of the hiccups was 14 ± 23 sec in group A and 12 ± 11 sec in group B (n s) The mean age levels between children with or without midazolam-induced hiccups were 5 ± 9 months vs 21 ± 19 months in group A ($p < 0.01$) and 6 ± 7 months vs 20 ± 14 months in group B ($p < 0.01$).

Conclusions: The most important finding of our study is that intranasal chlormethyl-spray application is an effective therapy with no side effects for midazolam-induced hiccups in pediatric anesthesia The incidence of midazolam induced hiccups is high significantly age but not dose dependent. Because of the high incidence of midazolam induced hiccups intranasal chlormethyl-spray application is a possible therapy for this symptom in pediatric anesthesia

A.498 Reinforced laryngeal mask airway for adenotonsillectomy in children: problems and comparison with tracheal intubation

F. Cassinello, L. Ruiz, L. Muñoz, J. Rodrigo, A. Mayor, J C De la Pinta.
Fundación Jiménez Díaz, Avda. Reyes Católicos, 2 28040 Madrid, Spain

Background and Goal: Reinforced Laryngeal Mask Airway (RLMA) is an alternative to tracheal intubation for adenotonsillectomy With the laryngeal mask you do not need to use muscle relaxants and previous studies show less incidence of laryngeal spasm (1, 2). The aim of this prospective non randomized study is to evaluate the use RLMA for adenotonsillectomy in paediatric patients We will also compare the incidence of laryngeal spasm at the end of surgery in a group of intubated children.

Patients, Material and Methods: 30 consecutive children; 2 to 9 years (4.83 ± 1.95), 9 girls and 21 boys were included The retrospective control group included the last 16 children, 2 to 10 years (4.35 ± 1.87), 5 girls and 11 boys, that were intubated. Anaesthesia for both groups included. induction with sevoflurane, intravenous line: propofol 1 mg/kg, atropine 0.01 mg/kg and fentanyl 1–2 mcg/kg The control group also received succinylcholine 1 mg/kg for tracheal intubation. Maintenance of anaesthesia: nitrous oxide 50–66% and sevoflurane 2–3%. We studied in the control group the incidence of laryngeal spasm at the end of surgery. In the RLMA group we studied: problems with RLMA insertion (air leakage, cough, number of tries); problems with mouth gag insertion and during surgery (oxygen desaturation, airway obstruction or laryngeal spasm, RLMA displacement, surgical access) and problems at the end of surgery (airway obstruction or laryngeal spasm, cough). We compared the incidence of postoperative laryngeal spasm in RLMA and intubated children (Chi square, $p < 0.05$).

Results: Only one patient required reinsertion of RLMA; air leakage in one child before opening mouth gag; we had to relieve the mouth gag and open it again in four cases because the LM tube was in the middle of the mouth and in one case due to RLMA tube obstruction; only once the surgeon referred a difficult access related to a small oral cavity, RLMA displacement 2 cases; only one case of laryngeal spasm after RLMA removal. In the tracheal tube group the incidence of laryngeal spasm was 25% (4 of 16)

Conclusions: RLMA reduces the incidence of laryngeal spasm compared with tracheal intubation and is safe in adenotonsillectomy

A.499 End-tidal and transcutaneous carbon dioxide monitoring during paediatric laparoscopic surgery

M. Dubreuil, F Maigrot, B Grenier, Y. Meymat, F Masson, L Sanz,
A. Dupeyrat *Departments of Anaesthesia, Bordeaux University, France*

Background: End tidal carbon dioxide (PetCO2) is monitored during paediatric laparoscopy to approximate arterial (Pa)CO2. A good correlation between PaCO2 and transcutaneous (Ptc)CO2 monitoring has been demonstrated during adult anaesthesia (1).

Goal of Study: To prospectively compare end tidal PetCO2 and PtcCO2 changes during paediatric laparoscopy in order to adjust ventilation

Materials and Methods: After institutional and parental approval, 21 ASA I–II children (2–14 yrs) were studied. Exclusion criteria were: cardiovascular, respiratory and haemoglobin diseases and morbid obesity. PtcCO2 sensor heated to 44°C (Kontron®) was applied above right claviocula. Children were induced with halothane (1.5–2.5 MAC) or with propofol and maintained with muscle relaxant, fentanyl and isoflurane (1.2–1.8 MAC) through endotracheal tube PetCO2 (Capnocap® Datex) was applied to every children. Their lungs were ventilated with FiO2 50% (air/O2) and a minute ventilation = [10 ml/kg frequency 10 ml/kg frequency adjust to the age]. Ventilator settings were kept constant during the study. Data were collected before CO2 peritoneal inflation (TO), 5 min after insufflation (T5), then every 10 min and at exsufflation (Texs) Data were analysed with ANOVA for repeated measures and Fisher's PLSD and expressed as mean ± SD with $p < 0.05$ significant. CO2 measurement techniques were compared with the Bland & Altman plot.

Results: Age was 7.2 ± 4.5 years and weight 30.2 ± 18.4 kg There is a significant increase of PetCO2 with time ($P < 0.05$) without any change of PtcCO2. The bias (comparison between the two methods) is 0.8 mmHg with agreement limits of –8 and 6.4 mmHg (bias ± 2SD).

	T 0	T 15	T 20	T Exs
PetCO2	30 ± 4.5	34 ± 6*	36 ± 5.5*	36 ± 7*
PtcCO2	29 ± 5	31 ± 6	33 ± 5.5	33 ± 7

Mean ± SD for PetCO2 and PtcCO2 (mmHg), * $p < 0.05$, vs T0

Discussion: It seems important to reconsider changes in PetCO2 as a non accurate estimate of PaCO2 When P(a-et)CO2 gradient becomes negative, PetCO2 overestimates PaCO2 (2) A range of 14 mmHg difference between the two techniques is of clinical importance. Adjustment of ventilator settings using only PetCO2 is inappropriate during paediatric laparoscopy; PetCO2 should be compared with PtcCO2 or PaCO2 to limit the risks of hyperventilation.

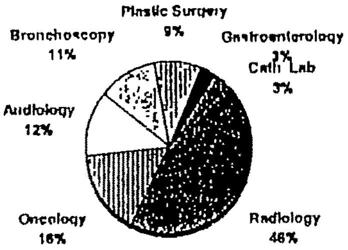
A.500 A paediatric sedation unit in a university hospital: a one-year survey

D. Gozal, A Kadan, Y. Gozal *Dept of Anesthesiology and CCM, Hadassah University Hospital, Jerusalem, Israel*

Background: Increases in diagnostic and invasive medical, surgical and radiological procedures in children have resulted in escalating need for anesthetic care in non-operating room locations We report the initial results of 1-year activity of our pediatric sedation unit

Materials and Methods: Between May 1996 and May 1997, ASA I–III patients, less than 18 years old, were sedated-anesthetized by our sedation team [composed of an anesthesiologist, specialist in pediatric anesthesia and a nurse anesthetist certified in pediatric intensive care] in remote locations: radiology (CT, MRI, radiation therapy, interventional radiology), oncology clinic, gastroenterology clinic, bronchoscopy suite, audiology and visual research institutes, cardiac catheterization laboratory (including electrophysiological studies), and pediatric plastic surgery clinic, in a 800-bed university hospital An anesthesia machine, scavenging suction, O2 source and routine monitors (pulse oximetry, ECG, automatic blood pressure, capnometer, precordial stethoscope, temperature) were available at all remote locations Following each procedure, recovery was managed in a suitable environment. The data was retrieved from our computerized database

Results: During this 1-year period, 1300 sedations-anesthetics were provided to 1100 patients aged 6 months to 18 years (mean ± SD = 5 ± 4 years). The average number of cases was 93/month. Average duration of cases was 60 min (range 30–120 min). ASA repartition was I (18%), II (76%), and III (6%) Radiology was the most involved department (44%), followed by the oncologic clinic (16%) (fig. 1). Propofol was the drug of choice in 55% of the cases whereas triclofos (27%) and midazolam (18%) were less used.



Conclusion: The creation of this pediatric sedation unit has offered the possibility of doing complicated cases, that were previously only done in the OR, in their natural environment. The increasing demand for remote sedation-anesthetics confirms the mutual satisfaction of physicians, nurses, technicians, parents, and above all children.

A.501 Physical and emotional conditions after ambulatory paediatric surgery: results of 413 questionnaires as part of postoperative quality assurance

M. Kumm. *Klinik für Anästhesie, Klinikum St. Marien, D-92224 Amberg, Germany*

Day surgery is a small but growing part of medical care in the German health system To overcome traditional and still current objections quality control is an important tool. As a first step in the improvement of ambulatory care in our 600 bed city hospital we used a questionnaire to evaluate the incidence of typical postoperative complications and of short-termed behavioral changes.

Methods: Over a period of 12 months we asked the parents of 552 pediatric day care patients (age 6 m–12 y) to fill out a questionnaire 48 hours after treatment Midazolam 0.5 mg/kg (max. 15 mg) was given orally for premedication Anesthesia was provided for surgery in the ENT-, urological, dental (MKG) and surgical department. Induction was performed via inhalation (halothane, N_2O, O_2) or intravenously (thiopentone and suxamethonium/atracurium or propofol/remifentanil) and continued with halothane and N_2O/O_2 Paracetamol 30 mg/kg was given rectally as analgetic during the procedure and Nalbuphin 0.3 mg/kg was added intravenously in the PACU if necessary The patients were permitted to go home after they met our strict requirements for discharge.

Results: 413 questionnaires (74.8%) were returned Patients of the questionnaire-group were comparable to the whole population concerning age (4 9 ± 2.5 y vs 5 0 ± 2 5 y), weight (20.1 ± 9.0 kg vs 20 1 ± 8 6 kg) and premedication (0 42 ± 0.14 mg/kg vs 0 42 ± 0 14 mg/kg) The procedures were distributed as follows ENT 65 6%, surgery 10.4%, urology 13.3%, MKG 10.2%, others 0 5% Anesthesia was performed with endotracheal intubation in 86.2%, mask ventilation in 9.4%, laryngeal mask in 4.1% and ketamine iv in 0 2% Complications occurred intraoperatively in 4 cases (1%), but discharge home was not delayed and no patient had to be admitted for inpatient treatment At home treatment with analgetics was necessary in 34 6% (Paracetamol 88 4%, ASS 1 0%, others 10.6%). The general practioner or the hospital had to be contacted by 2 patients (1 persistent vomiting, 1 postoperative hemorrhage) after returning home 92 5% of all parents were satisfied with all aspects of their children's treatment and 7.5% were not. 91 3% would prefer a future surgical treatment on day care basis, 2 4% would prefer inpatient care and 6.3% couldn't decide

	PACU	Transfer	24 h	48 h
Nausea	21 3	10 4	8 2	0 2
Vomiting	16.2	10 4	14 8	0 7
Pain	44 3	35 8	50 1	22 5
Dizziness	31 5	19 6	3 6	0 0

Discussion: Postoperative nausea and vomiting were comparable with other publications (1, 2) The high incidence of pain until 48 hours postoperatively was the reason for an accurate revision of our analgetic regime. For better monitoring we introduced an additional phone call in the evening after surgery

A.502 Adverse effects after paediatric magnetic resonance imaging

A. Sandner-Kiesling[1], M Vizenci[1], A Fall[1], G Schwarz[1], F Ebner[2], W.F. List[1]. *Dept. of Anesthesiology and [1] Intensive Care Medicine; [2] MRI-Institute, University of Graz, Austria/Europe*

Background & Goal of Study: To find out type, incidence and duration of adverse effects in children after anesthesia for Magnetic Resonancy Imaging (MRI) questionnaires were handed out to parents.

Materials & Methods: MRI examinations in anesthesia (duration 46 ± 16 min; 23–155 min) were performed in 140 children (mean age 3.75 ± 2 8 years; 6 days–13 yrs) After premedication with midazolam (0.1–0.2 mg/kg BW iv) and atropine (0 01 mg/kg BW iv.) anesthesia was induced with thiopental sodium (5–8 mg/kg BW iv.) Maintenance was done with isoflurane (0.6–1 0 Vol%) in 77 children (55%), sevoflurane (0 7–1.0 Vol%) in 36 children (25.7%), desflurane (1–3 Vol%) in 14 children (10%), and halothane (0 6–0.8 Vol%) in 12 children (8 6%) in an oxygen/air mixture (FiO_2 = 0 4; flow 51/min) using an open mask in supine position In each patient a conventional multiparametric cardiorespiratory monitoring was performed [1] 0.1 mmol/kg BW Dimeglumingadopentetat was used in 60 children (43%) as contrast agent Questionnaires about postanesthetic adverse effects within the first 72 hours were handed out to 201 parents For statistics contingency analysis was used.

Results & Discussion: Responses were received from 140 parents (69 7%) out of 201 Adverse effects were reported for the time of 1 hour (n = 54), 24 hours (n = 25), and even 72 hours (n = 19) after MRI examination. Solitaire adverse effects were found in 68, combined in 25 children. In 66 children different adverse effects were reported: restlessness (n = 28), nausea (n = 18), vomiting (n = 17), singultus (n = 11), conjunctival injections (n = 10), rhinitis (n = 8), diarrhea (n = 7), tiredness (n = 7), rash (n = 7), dizziness (n = 4), headache (n = 2), flatulence (n = 2), abdominal pain (n = 1), fever (n = 1), laryngitis (n = 1), asthma (n = 1) None of the inhalational agents showed a statistical significance in the incidence of adverse effects [2].

Conclusions: MRI examinations induce a high variance of adverse effects More than one adverse effect is possible, the appearance is not predictable and occurs within the first 72 hours of observation time To evaluate whether anesthetic or contrast agents cause the adverse effects, further studies are necessary Parents should be informed about the increased incidence of adverse effects after diagnostic procedures for MR Imaging in anesthesia

A.503 Tonsillectomy for children: evaluation for ambulatory practice

S. Colombani, C Boudey, D Esteben, M. Milacic, A M Cros *Department of Anaesthesia-Reanimation IV, Hospital Pellegrin-Enfants, 33076 Bordeaux cedex, France*

Goal of Study: is to evaluate the safety of ambulatory anaesthesia (1) in tonsillectomy considering monitoring criteria six hours pre and postoperative.

Materials & Methods: This prospective study concerns 206 children ASA I having tonsillectomy. The average age is 5 ± 2 6 years All of them were premedicated with midazolam given orally or rectally The induction was either by inhalation of halothane or intravenous injection of propofol All children had an intravenous line, were orotracheally intubated and manually ventilated Fentanyl (2 µg/kg) was only given to 56% of them Maintenance of anaesthesia was provided by inhalation of halothane or isoflurane in 50% gaz mixture Heart rate, blood pressure and SaO_2 were monitored all through the surgery and in PACU The anaesthesia's average time was 23 ± 14 min Two surgical techniques were used· the guillotine tonsillectomy for 86% and the dissection for 14% Postoperative analgesia was conducted by diclofenac rectally and intravenous propacetamol immediately postoperative, repeated four hours later, then taking over with paracetamol rectally Early postoperative detection of respiratory, bleeding complications as well as monitoring of pain (C H E.O P S 's scale) and vomiting were recorded during the first hour (H), every hour during six hours and every two hours during the first twenty-four hours postoperative

Results and Discussion:

In PACU	≤H6	>H6
Desaturation 22		
Vomiting 14	vomiting 61	
Bleeding with revision 2	bleeding with revision 5	bleeding with revision 1
	without revision 5	
Week pain 105	great pain. 7	pain with revision 1

Children with no complications during the first six hours did not have complications beyond the sixth hour

Conclusion: In tonsillectomy, children without morbidity during the first six hours postoperative (87%) could be the subject of an ambulatory anaesthesia, provided that strict monitoring protocole is used

A.504 Evaluation of sevoflurane anaesthesia for children requiring cardiac catheterization

C. Giannelloni, F. Abdo, C Dauphin[1], I Curt, M. Montetagaud, J E Bazin. *Département d'Anesthésie et de Réanimation; [1] Cardiologie, CHU, 63003 Clermont-Ferrand, France*

Background and Goal of the Study: General anaesthesia for cardiac catheterizations for children with congenital heart diseases is a real challenge Sevoflurane (S) which allows inhalation induction and a rapid return to consciousness combined with few cardiovascular effects 1 might well be useful. We assessed the characteristics of anaesthesia using S in this indication.

Patients and Methods: After explanation and agreement from the parents, 40 consecutive child patients aged 4 months to 10 years who were scheduled for cardiac catheterization were anesthetized according to a standardized protocol 0.35 mg/kg intrarectal midazolam and application of EMLA 1 h before the procedure ECG monitoring, noninvasive arterial pressure, SpO2. Induction by inhalation with 8% S in a mixture of air + O2 (FiO2:0.21) (TO) After the eyelash reflex disappeared (T1) the concentration of S was lowered to 3 5% until a laryngeal mask was inserted (T2). A venous line was installed (G5%, 10 ml/kg/h) The concentration of S inhaled was then kept at between 1.5% and 3% with O2 + air (FiO2 0 21) depending on movement or no movement occurred to stimulus At the end of the procedure, administration of S was stopped when vascular compression ended, after withdrawal of the introducing devices. The times (T0–T1), (T0–T2) and the times between interruption of S and eyes opening, removal of the laryngeal mask and the first cry, together with the time at which the child left the recovery room were assessed. All the side effects during induction, procedure and recovery were noted The results are expressed as means ± SD.

Results and Discussion: 18 boys and 22 girls, mean age 3 years 3 months ± 2 years 8 months were anesthetized using this protocol The times T0–T1 and T0–T2 were respectively 34 ± 8 s and 217 ± 35 s The side effects to induction were· cough (2), brief agitation (5), apnea (8) of which 5 resulted in a drop of SpO2 > 5% of initial value, requiring manually assisted ventilation. The facial mask was always remarkably well accepted The mean duration of anesthesia was 57.5 ± 13 min and the mean concentration of S inhaled during catheterism was 2 1 ± 0.4%. The changes in arterial pressure and levels of ETCO2 never exceeded ± 20% of the base values. In 5 cases desaturation was observed during catheterism corrected by enriching the 02 content of the mixture inhaled. Recovery time was 6.3 ± 2 1 min for ablation of the laryngeal mask, 7.1 ± 3.5 min to the first cry and 8 4 ± 3.8 min to eyes opening. On average 12.5 ± 4 3 min after S ceased to be administered, all the children presented PACU discharge criteria. The side effects observed during recovery are headache 4, cough 2, agitation 2, shivering 1

Conclusion: Sevoflurane has few negative inotropic effects and provides very rapid loss and recovery of consciousness, so would seem to be well indicated for carrying out general anesthesia for diagnostic or interventional cardiac catheter procedures in young children with congenital heart diseases.

A.505 Spontaneous recovery of neuromuscular transmission after mivacurium in children under balanced, halothane and isoflurane anaesthesia

B Woloszczuk-Gebicka *Memorial Children's Health Institute, Warsaw, Poland*

Volatile anaesthetics significantly potentiate the neuromuscular (n-m) block produced by mivacurium (MIV). MIV requirement under halothane and isoflurane [1] anaesthesia is by 1/3 to 2/3 lower than under balanced anaesthesia, one may therefore expect that the presence of volatile anaesthetics may slow down the recovery from the n-m block.

Methods: With approval from the Institutional Ethics Committee and parental consent, 29 children (2–12 years old, ASA PS group I-II) scheduled for surgical procedures not exceeding 90 min were studied They were assigned at random to receive N_2O/O_2 narcotic (BAL), N_2O/O_2-halothane (HAL) or N_2O/O2-isoflurane (ISO) anaesthesia MIV, 0.2 mg kg^{-1} was given to facilitate intubation and MIV infusion was used during the surgery. The n-m block was allowed to resolve spontaneously. The n-m transmission was monitored by recording EMG activity of the adductor pollicis in the response to the supramaximal stimulation of the ulnar nerve at wrist with repetitive trains-of-four, 2 Hz for s, at 10 s intervals. Core body temperature was kept above 36°C. IPPV was used and normocapnia was maintained. End-tidal concentration of anaesthetics was and maintained at 1 MAC level throughout the procedure until the first twitch response (T_1) recovered >95% and TOF ratio (T_4/T_1) >90%. The time of the T_1 recovery from 25% to 75% (RF_{25-75}) and the time from the T_1 recovery from 10% to TOF ratio = 70% (T_{10}-$TOF_{70\%}$) were measured. ANOVA was used and p < 0.05 was considered significant)

Results: The study groups were similar in the respect of age and body weight. The parameters describing the recovery the neuromuscular transmission are summarised in the table.

	BAL n = 10	HAL n =.10	ISO n = 9
RF_{25-75} (min)	4 3±2 2 [1.5–0 3]	5.3±1 2 [3 5–0 2]	5 3±1.4 (NS) [4.2–7 2
T_{10}-TOF_{70} (min)	8 1±3 3 [3 3–14 8]	9.9±2 4 [6 2–14.6]	11 5±3 8 (NS) [6 0–18 2]

Values are given as mean (±SD) and [range]

Conclusions: Even though the recovery of the n-m transmission takes a little longer in the presence of volatile anaesthetics than under balanced anaesthesia, it remains short and reliable. It seems that the spontaneous recovery from the n-m block produced by mivacurium can be allowed even in patients anaesthetised with halothane or isoflurane

OBSTETRIC ANAESTHESIA

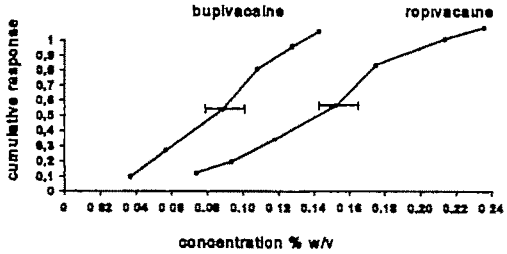
A.506 Determination of the minimum local analgesic concentration of epidural ropivacaine in labour

G. Capogna[1], D. Celleno[1], G. Lyons[2], M. Columb[3]. *Departments of Anesthesiology, [1]Fatebenefratelli Hospital, Rome, Italy; [2]St James's University Hospital, Leeds; [3]Manchester University Hospital, UK*

Background: The concentration of ropivacaine to be used for labor analgesia has been arbitrary decided[1, 2]. A clinical model was devised to determine the effective local anesthetic concentrations in 95% (EC_{95}) as well as in 50% of patients (EC_{50}) and EC_{50} was defined as the minimum local analgesic concentration (MLAC)[3]. The aim of this study is to determine the MLAC of ropivacaine and to determine the relative analgesic potencies of bupivacaine and ropivacaine for labor analgesia.

Methods: After Institutional Ethical approval, 88 healthy primiparus women, at more than 37 weeks gestation requiring epidural analgesia for labor pain were enrolled in the study. After epidural catheter placement, 20 mL of the local anesthetic solution being tested was given. The concentration was determined by the response of the previous patient to a higher or lower concentration using double-blinded, up-down sequential allocation. Efficacy was assessed using a 100 mm visual analogue pain scores (VAPS) scale with less than 10 mm within 1 hour defined as effective MLAC was determined by the Dixon and Massey formula[4].

Results: No differences were noted in demographics. Of the 44 women entered into the ropivacaine group, 4 were rejected, leaving 40 for analysis. MLAC of ropivacaine was 0.156% (95% CI 0 136 to 0.176) Of the 44 women entered into the bupivacaine group, 3 were rejected, leaving 41 for analysis. MLAC of bupivacaine was 0.093% (95% CI 0 076 to 0 110). (MLAC of ropivacaine vs: bupivacaine P < 0 0001, 95%CI 0.036 to 0.090). The concentration response plots are reported in the figure. Relative median potency of ropivacaine to bupivacaine was 0.60 (95%CI 0 42 to 0 77). Molar EC_{50} (MLAC) was 5.02 mmol/L (95% CI 4.37 to 5 66) for ropivacaine and 2.86 mmol/L (95% CI 2.33 to 3.38) for bupivacaine Molar potency ratio was 0.57 (95% CI 0.40 to 0 74)



Conclusions: Ropivacaine is significantly less potent than bupivacaine. By using the MLAC data it should be possible to optimize the concentration of local anesthetic to provide the greatest effect at the minimum disadvantage.

A.507 A comparison of ropivacaine 0.10% and sufentanil 10 μg with ropivacaine 0.20% for epidural labour analgesia

D. Celleno[1], G. Capogna, D. Quarta, A. Amato[2], M. Emanuelli.
Departments of Anesthesiology, [1]St James's Hospital, Fatebenefratelli Hospital; [2]Catholic University, Rome, Italy

Background: The addition of opioids to local anesthetic for labor analgesia is a well established technique. In this study we evaluated the effects of the addition of sufentanil to ropivacaine for epidural labor analgesia.

Methods: Forty nulliparous parturients, with uncomplicated pregnancies and a cervical dilatation at 2 to 5 cm were randomly allocated to receive epidural analgesia with 20 mL of ropivacaine 0.20% (n = 20) or ropivacaine 0.10% plus 10 μg of sufentanil (n = 20). Monitoring of FHR and uterine activity was started at least 10 min before induction of epidural block. Maternal blood pressure, HR and SaO_2 were monitored before induction and every 5 min. Pain of contractions was assessed on a 100-mm visual analogue pain scale (VAPS) every 5 min Onset time was defined as the time from the injection to pain relief (with a VAPS at least <20). Duration of action of each dose was defined as the time from injection to request for further pain relief Statistical analysis was performed using unpaired t-test or Mann Withney U-test, where appropriate.

Table 1

	Ropivacaine 0 20%	Ropivacaine 0.10% with 10 μg sufenta
Onset of analgesia (min)	18 2 (3 5)	15 5 (3.5)
Duration of analgesia (min)	130 (9 7)*	101 (26 7)

*P < 0.0001, t-test

Results: The two groups were comparable with regard to age, weight, height, cervical dilatation and VAPS before epidural. The analgesia was satisfactory in all cases. Analgesia was significantly longer (P < 0.0001) with the higher concentration of ropivacaine In the 0.20% ropivacaine group, five parturients have moderate hypotension (<90 mmHg) and one patient had severe and prolonged hypotension requiring i.v. ephedrine Only patients who received sufenta had transient, moderate pruritus The lower concentration of ropivacaine allowed for ambulation in all cases while only four patients receiving the higher concentration were able to walk alone.

Conclusions: The addition of 10 μg of sufenta to 0.10% ropivacaine produced a maternal analgesia similar to that produced by 0 20% ropivacaine with a similar onset time Although the duration of analgesia was approximately 30 minutes longer with 0 20% ropivacaine, patients receiving 0 10% ropivacaine and sufenta were able to walk and had less hypotension and these features may be of great advantage for labor analgesia

A.508 Ropivacaine 0.10% plus sufentanil and bupivacaine 0.0625% plus sufentanil are equianalgesic mixtures for epidural analgesia during first stage of labour

G. Capogna, D. Celleno, D. Quarta, A Amato[1] *Departments of Anesthesiology, Fatebenefratelli Hospital, [1]Catholic University, Rome, Italy*

Background: On the basis of a previous study we determined that the ropivacaine bupivacaine potency ratio is 0 60 (unpublished study) In this study we evaluated the analgesic effects of two equianalgesic concentrations of ropivacaine and bupivacaine during the first stage of labor.

Methods: 44 nulliparous parturients, with uncomplicated pregnancies and a cervical dilatation at 2 to 5 cm were randomly allocated to receive epidural analgesia with 20 mL of 0 10% ropivacaine and 10 μg of sufentanil or 0.0625% bupivacaine with 10 μg of sufentanil Monitoring of FHR and uterine activity was started at least 10 min before induction of epidural block Maternal blood pressure, HR and SaO_2 were monitored before induction and every 5 min Pain of contractions was assessed on a 100-mm visual analogue pain scale (VAPS) every 5 min. Onset time was defined as the time from the injection to pain relief (with a VAPS at least <20) Duration of action of each dose was defined as the time from injection to request for further pain relief

Table 1

	Ropivacaine	Bupivacaine
Onset (min), mean (sd)	14 5 (2 9)	18 3 (7 6)
Duration (min) mean (sd)	100 (25 4)	96 5 (31)
Ability to walk (n of patrunents)	44 (100%)	44 (100%)

Results: The two groups were comparable with regard to age, weight, height, cervical dilatation and VAPS before epidural The analgesia was satisfactory in all cases Median values of VAPS were comparable during the period of observation. There was no lower limb weakness and the parturients were able to walk without difficulty. Non changes in FHR were detected. No maternal hypotension was observed.

Conclusions: According with the potency-ratio, the two concentrations examined were equianalgesic in potency and duration Further studies are in progress to evaluate the use of a such ultra-low concentration of ropivacaine for epidural continuous infusion.

A.509 Epidural analgesia, progress of labour and maternal motor blockade. A comparison of ropivacaine and bupivacaine

G Gobber, T. Battistini, G. Apollonia, N. Facchin, R. Cassol, M C Luise, A. Mazzaro, A Tanfani, F. Laterra, L. Chianni *Dept. of Anaesthesia, General Hospital Feltre, Italy*

Aim of the Study: Aim of this study was the evaluation of the efficacy of peridural analgesia with ropivacaine and bupivacaine in different concentrations during labour and delivery, with reference to the progress of labour.

Materials and Methods: By previous informed consent and request, 75 women received peridural analgesia for labour and delivery, they were divided in 5 groups

Group 1 Bupivacaine 0 125% 10 ml bolus and infusion rate of 5 ml/h;

Group 2: Bupivacaine 0 125% 15 ml bolus and infusion rate of 10 ml/h;

Group 3; Ropivacaine 0.2% 10 ml bolus and infusion rate of 5 ml/h,

Group 4: Ropivacaine 0.2% 10 ml bolus and infusion of ropivacaine 0.1% at the rate of 10 ml/h;

Group 5: Ropivacaine 0.2% 10 ml bolus and infusion of a solution with ropivacaine 0.75 mg/ml at the rate of 10 ml/h.

We evaluated: The analgesic efficacy using VAS 30 minutes after the onset of infusion and during fetal expulsion, bromage scale and the onset of paresthesia, the length of fetal expulsion and the necessity of ventouse extraction delivery.

Results:

Every group showed apgar scores and the data on the progress of labour of complete safety The best results on analgesic efficacy were obtained by groups 2 and 5, with the difference that in group 5 motility was not so affected as in group 2. Excluding the data about cesarean sections, all the groups with ropivacaine have a lower rate of ventouse extraction delivery and better score of bromage scale.

Conclusions: In every group satisfactory results were obtained. The results of the present study seem to point out a good analgesic efficacy of ropivacaine with a lower motor blockade than bupivacaine Further studies would be appropriate for evaluating the higher rate of vomiting and nausea in the groups treated with ropivacaine.

A.510 Ropivacaine 2 mg/ml *vs* ropivacaine 1 mg/ml + sufentanil 0.2 μg/ml for extradural analgesia in labour

S Lopez, J.M Ferrer, G Aya, R Mangin, C Robert, J J Eledjam
Département d'Anesthésie réanimation, Hopital Carémeau, Rue du Pr Debré, 30029 Nimes cedex, France

Background and Goal of the Study: The recommended ropivacaine concentration for the maintenance of épidural labor analgesia is 2 mg/ml, using 6 or 8 ml/h The purpose of this randomized study was to compare ropivacaine 2 mg/ml with ropivacaine/mg/ml + sufentanil 0 2 μg/ml used for the maintenance of analgesia

Materials and Methods: 25 healthy parturients with singleton, uncomplicated pregnancies, in active labor were included after the epidural analgesia induction with ropivacaine in sufficient amount to obtain a good quality of analgesia The parturients were randomly allocated to one of the two groups to receive continuous extradural infusion either ropivacaine 2 mg/ml or ropivacaine 1 mg/ml + sufentanil 0.2 μg/ml. The continuous extradural infusion rate in both groups was 6 ml/h if the woman was less than 160 cm tall and 8 ml/h if she was more than 160 cm Additional boluses of 5 ml of ropivacaine 2 mg/ml were injected if necessary Visual analogic pain score, dilatation, analgesia sensory level and degree of motor block were measured at the beginning of continuous infusion, 30 mn later and hourly to the beginning of expulsive efforts Maternal satisfaction was assessed when the analgesia was achieved and the lumbar catheter withdrawn

Results and Discussion: The two groups were comparable concerning age, height and term Maintenance dose of ropivacaine was higher in the 2 mg/ml group 97 17 mg versus 69 27 mg ($p < 0.05$) Visual analogic pain score at any time was not statistically different between the two groups But, the last one before delivery was higher in the 1 mg/ml + sufentanil group The mean superior sensitive level was comparable in the two groups (mean level = T9). There were more motor blocks in the 2 mg/ml group 4/12 versus 1/11 ($p > 0\ 5$) and one of the women in the 2 mg/ml group has a Bromage score egal to 2. Maternal satisfaction scores were not statistically different between the two groups

Conclusion: Ropivacaine 1 mg/ml + sufentanil 0.2 μg/ml seems to be adequate during labor analgesia, and permit to use less local anesthesic But, ropivacaine 1 mg/ml + sufentanil 0 2 μg/ml is inadequate for the second stage of labour and needs an additional bolus just before expulsive time

A.511 Minimum local analgesic volume for epidural bupivacaine 0.125% in labour

G. Lyons, M O Columb, H. Gorton *Obstetric Anaesthesia, St, James's University Hospital, Leeds, UK*

Background and Goal of Study: Epidural analgesia in labour with plain bupivacaine 0.125% is associated with a significant failure rate[1]. And yet this is a concentration that lies on the flat upper part of the dose response curve for epidural bupivacaine [2], implying that it should be effective in most instances.

We performed this study to examine the role of bolus volume in pain relief in labour with bupivacaine 0.125%

Materials and Methods: Ethics approval and informed consent were obtained 50 women requesting epidural pain relief in labour were recruited The syringe volume of the initial bolus was decided by double blind up and down sequential allocation using a 1 ml dosing interval No test dose was given, and the first woman received an arbitrarily chosen 15 ml bolus Opaque syringes were used. Efficacy was accepted if visual analogue pain score (VAPS) fell to 10 or less within 30 minutes.

Results:

Age	Mean (SD)	27 7 (6 7)
Weight	Mean (SD)	77 9 (15 1)
Height	Mean (SD)	163 4 (5 7)
Gestation	Med (IQR)	40 (40–41)
Nullips	Count	27
Cervix	Median (IQR)	2 (2–3)
Initial VAPS	Median (IQR)	70 (57–84)

The effective volume in 50% of the women studied was 17.7 ml (95%CI 15 2–20.2).

Discussion: Our findings suggest that previously reported failures of analgesia with plain bupivacaine 0 125% w/v were due to inadequate volume

17 7 ml of 0 125% w/v contains 22 mg bupivacaine. The same analgesic point can be achieved with 20 ml 0.07% w/v [2], which contains 14 mg bupivacaine. Plain bupivacaine 0.125% is not an efficient solution for use in epidural pain relief in labour.

A.512 Patient-controlled analgesia: extradural fentanyl and intravenous morphine compared after Caesarean section

U Saleh, D Cooper, D Ryall, K. Kokri, W Desira, M. Tremlett
Department of Anaesthesia, South Cleveland Hospital, Middlesbrough, Cleveland TS4 3BW, USA

Background and Goal of Study: Following Caesarean section patient-controlled extradural fentanyl (PCEF) has been found to produce effective analgesia with a remarkably low incidence of nausea and vomiting (1, 2). This study was designed to compare PCEF with patient-controlled intravenous morphine (PCIM).

Materials and Methods: After ethical approval, 84 ASA I–II women having an elective Caesarean section in the morning, under a standard combined intrathecal and extradural (CIE) anaesthetic, were entered into this randomised, double-blind, study. Patients were attached to both extradural and intravenous patient-controlled analgesia (PCA) devices in the recovery room. The extradural PCA device was programmed to allow a 5 ml bolus with a 10 minute lockout interval and the intravenous PCA device to allow a 0.5 ml bolus with a 5 minute lockout. Group PCEF received extradural fentanyl 4 μg/ml and intravenous normal saline. Group PCIM received extradural normal saline and intravenous morphine 2 mg/ml. Patients were told to use both PCA devices. Patients were assessed in recovery, at 4 h and 8 h after delivery, at 2300 and at 0800. Mann-Whitney and Kruskal-Wallis tests were used to analyse data

Results and Discussion: Groups PCEF (n = 42) and PCIM (n = 42) were matched. All patients received rectal diclofenac at operation. PCEF patients used a median of 18 μg/h (interquartile range (IQR) 11–32) of fentanyl. PCIM patients used 1.7 mg/h (1 2–2 4) of morphine The mean hourly volume of intravenous PCA solution delivered was 41% lower for PCEF than for PCIM patients (P = 0.002). Pain scores were lower for PCEF at 4 h, 8 h and 0800 The highest pain score (VAS 0–100 mm) experienced at rest for PCEF patients was median 19 (IQR 10–33) compared to 32 (14–52) for PCIM patients (P = 0 02). On coughing the highest score was 31 (21–41) for PCEF compared to 56 (31–71) for PCIM (P = 0.0003) There was less Nausea (N) and vomiting (V) with PCEF (N = 14%, V = 2%) than with PCIM (N = 33%, V = 12%) (P = 0.03). There was also less drowsiness with PCEF from 8 h onwards; this was most marked at 0800, when 14% were drowsy with PCEF compared to 58% with PCIM (P = 0 0002). Pruritus was similar with both regimes.

Conclusion: PCEF produced more effective analgesia, with less nausea, vomiting and drowsiness, than PCIM We consider it to be a practical alternative to PCIM

A.513 Effect of fluid preload on coagulation as measured by thromboelastography

H. Gorton, G. Lyons, P Manraj. *St. James's University Hospital, Leeds, UK*

Background and Goal of Study: During pregnancy, thromboelastography (TEG) shows a hypercoagulable state [1]. Moderate haemodilution also enhances coagulation We studied the effect of preloading patients presenting for caesarean section on TEG parameters.

Materials and Methods: After informed consent and ethical committee approval, we performed TEG on 20 patients undergoing caesarean section with spinal anaesthesia, before and after infusion of 500 mls of colloid. Data was collected and analysed using an SPSS computer package

Results:

	Mean Diff	95% CI	Sig
R time	6 85	0 35, 13 35	0 04
K time	3 80	1 51, 5 48	0 02
R + k time	10.35	2.39, 18 30	0 013
α angle	−7.00	−12 9, −1 13	0 022
MA	0 675	−4.03, 5 38	0 767

Discussion: We have found small but statistically significant changes in TEG variables that indicate that preloading patients enhances coagulation. This has been reported in in-vitro studies [2], and also in in-vivo studies in patients undergoing general surgery [3] It is not clear whether these changes are clinically relevant.

Conclusion: This in-vivo study agrees with published in-vitro studies of the effect of preload on TEG. Preloading induces a hypercoagulable state

A.514 Effects of the Valsalva manoeuvre on the cerebral circulation in pregnancy

R Buckland, D. Radakrishna, J. Pickett, B. Matta *Department of Anaesthesia, Addenbrooke's Hospital, Cambridge, CB2 2QQ, UK*

Background and Goal: The Valsalva manoeuvre (VM) has been used to assess cerebral autoregulation in volunteers Labour often involves periods of straining similar in nature to VM. This study was designed to investigate the changes in cerebral blood velocity during the VM and to explore its potential use for the evaluation of cerebral autoregulation in late pregnancy.

Materials and Methods: With local ethics committee approval and informed consent, 7 healthy pregnant women (>34 weeks gestation) were recruited. All patients had their arterial blood pressure (Finapress, Ohmeda, USA) and blood velocity in the middle cerebral artery (Vmca) continuously monitored The Vmca was measured using a 2 MHz transcranial Doppler probe (DWL, Sipplingen, Germany) which was fixed in position throughout the study period. After adequate instruction and a period of stable arterial and Vmca reading, patients were asked to perform 3 VMs. The VM were performed in a semi-recumbent position by taking a deep breath and forcefully exhaling against a closed valve connected to an anaeroid pressure gauge aiming to maintain a pressure of 30 cm water for 15 seconds. Changes in Vmca and mean blood pressure (MAP) during phase II and IV of the VM were used to calculate autoregulation indices (AR-II and AR-IV respectively) previously described.[1]

Results and Discussion: The main findings of this study are outlined in Table 1. The autoregulatory response to the valsalva maneuver in pregnant patients was lower than reported in the non-pregnant patient.

Possible indices of autoregulation

	AR-II	AR-IV
Pregnant	1 14 ± 0 44	1 07 ± 0 11
Non-pregnant	2 87 ± 1 3	1 36 ± 0 25

All values are mean ± SD.

Conclusions: Analysis of VM in pregnancy provides important information about cerebral autoregulation. This may be of value in assessing cerebral haemodynamics in pregnancies complicated by neurologic abnormalities such as pre-eclampsia.

A.515 Vascular effects of propofol and thiopentone in the isolated perfused human placental cotyledon

Reinhold H Jensen[1], Olav B. Petersen[2], Jørgen H. Christensen[1], Aksel Formann[2]. [1]*Department of Anesthesiology;* [2]*Research Laboratory, Department of Obstetrics and Gynecology, Aarhus University Hospital, Denmark*

Background: Concucting intravenous general anesthesia to women during pregnancy as well as for cesarean sectio, thiopental has for years been the well-established drug of choice (1). Since late eighties, propofol has gained use for the same purposes. We studied the effect of propofol and thiopental on the vasculature in the isolated perfused human placental cotyledon.

Materials and Methods: Placentas were obtained from 24 healthy women, all having had an uncomplicated pregnancy and a normal vaginal delivery. In two intact cotyledones the artery and the corresponding vein were cannulated, enabling as well perfusion of the fetal compartment of the cotyledones as monitoring the arterial pressure. Perfusion was started within 15 minutes of vaginal delivery of the placenta, using an aerated modified Krebs-Ringer solution. Perfusional flow rate was adjusted to a stable arterial pressure of 20–30 mm Hg. Preconstriction were done in half the experiments by continuous infusion of Thromboxane (U46619), achieving a stable arterial pressure 200–250% of the above resting pressure. Propofol and thiopental were administered by continuous infusion of incremental doses in 12 experiments each, half of these preconstricted

Results: Neither propofol nor thiopental had any effect on perfusion pressure in the non-preconstricted cotyledones. In the pre-constricted cotyledones perfusion pressure was reduced significantly by thiopental 32 yg/ml or propofol 4 yg/ml ($p < 0.05$, Mann-Whitney). Both concentrations are very high in the clinical relevant interval, but may both be reached in induction(2, 3)

Conclusion: This in vitro study suggests high concentrations of thiopental and propofol to exert a dilatational effect on the feto placental vasculature, if preconstricted by thromboxane

A.516 Incidence of fetal acidaemia after spinal anaesthesia for elective Caesarean section – a persistent trend in the midnineties?

G. Schuepfer, C. Konrad, M.D. Mueller, S. Durrer, H Bruhwiler *Institute of Anesthesiology, Kantonspital Lucerne, Switzerland*

Introduction: With an increasing frequency of Spinal anesthesias (SPA) for elective Cesarean sections the incidence of severe fetal acidemia also increased in a Swiss epidemiological study (1) One may argue that such historical data are biased and anesthesia care in the past was not consistent with recent standards of care. Therefore data from 1995 and 1996 were analyzed to see if this trend is consistent

Patients and Methods: The presented epidemiological study used data of the Swiss obstetric study group After exclusion of all cases with extraneous factors that may have affected the health of the neonate, umbilical artery pH, Apgar score, and other neonatal outcome measures with reference to anesthetic technique were analyzed The goal of the data filtering procedure was to eliminate all factors which could have influenced the choice of the anesthesia technique. Gestational age had to be between 37 and 42 weeks The Relative Risk of fetal acidemia and the Odds Ratio were calculated using the patients having c-section under general anesthesia as reference. For both parameters the 95% confidence interval was calculated In addition to the pH-values the neonatal well-being was analyzed similarly. P values of less than 0.05 were considered significant

Results: 1445 elective cesarean sections of the 75464 recorded deliveries entered the analysis (792 SPA, 406 Epidural anesthesia (EDA); 247 general anesthesia (GA)). The frequency of fetal acidemia ($pH < 7.10$) was significantly increased in the SPA group: Odds-Ratio 5 35 (95% Confidence Interval 1 82–17.7) compared to GA Apgar Scores and other measurements of neonatal well-being did not differ in all three groups.

Conclusion: The risk of severe fetal acidemia is clearly elevated after elective cesarean delivery after spinal but not epidural anesthesia compared to GA. It is not clear at present what possible causal relationship could exist between SPA and fetal acidemia.

A.517 Influence of urodilatin on perfusion pressure in pre-eclampsia. A study of the placental model *in vitro*

D. Szukiewicz[1], A. Szukiewicz[2], D. Maślińska[1], M. Olszewski[3]. [1] *Dept. of General & Experimental Pathology,* [2] *Dept. of Anaesthesia & Intensive Therapy, University School of Medicine, Warsaw;* [3] *Dept. of Gynaecology & Obstetrics, Medical Care Centre, Ostrów Mazowiecka, Poland*

Background & Goal of Study: The hypothesis that preeclampsia may be associated with an increase in the response of the placental arteries to vasoconstrictors is well known (1). Preeclampsia is characterized by hemoconcentration and plasma volume depletion It may alter atrial natriuretic peptide (ANP) mechanisms of liberation (2) Urodilatin (URO, CDD/ANP-(99–126) is a new member of the natriuretic peptide family isolated from human urine Intravenous URO infusion may be useful in treatment the preeclamptic hemodynamic changes in placental circulation. The goal of this work was to compare the perfusion pressure changes induced by URO in placentas from normal and preeclamptic pregnancies

Material & Methods: Placentas obtained from 12 nulliparas (6 cases of preeclampsia and 6 uncomplicated pregnancies, control) after elective cesarean sections, were perfused in vitro using modified Cedard manner Perfusion pressure, measured continuously, was the main parameter of changes in vascular status over 120 min period. Concentration-response curves to various doses of URO (given as infusion) were determined.

Results & Discussion: In our study, we found significantly higher ($p < 0\ 05$) decrease of perfusion pressure after URO administration in the group of preeclamptic placentas, compared to control placentas This effect was transient, and the period of lowering pressure has been found shorter in the preeclamptic group (statistical significance).

Conclusion: 1.) Response to urodilatin of the placental vasculature seems to be increased in preeclampsia, but this effect is temporary, **2.)** The range of placental vessels oscillations is wider in preeclamptic group

A.518 Intrapartum fetal oxygen saturation monitoring during epidural analgesia for labour

P Fusco[1], P. Forleo[1], G. Capogna, D Celleno *Departments of Anesthesiology and* [1] *Obstetrics, Fatebenefratelli Hospital, Department of Anesthesiology St James's Hospital, Rome, Italy*

Background: A pulse oximeter made specifically for non-invasive, continuous intrapartum monitoring of SpO_2 has been recently introduced[1] In this preliminary open study we investigated the possible effects of uncomplicated epidural analgesia on SpO_2 during labor and delivery

Methods: Forty five healthy nulliparous parturients, at term, with uncomplicated pregnancies in established normal labor with cervical dilatation at least 2 cm requesting epidural analgesia were recruited and gave their consent for this study At least 10 min before epidural analgesia, all parturients were monitored with blood pressure, pulse oximetry, HR and FHR, uterine contractions and non-invasive fetal SpO_2 by an HP 50XM and Nellcor N-400 monitors and all these data were continuously recorded on the CTG trace until delivery. All parturients received epidural analgesia with 20 mL of 0 0625% bupivacaine with 10 μg of sufentanil, followed by a continuous infusion (10 mL/h) of bupivacaine 0 03% with sufenta 5 μg/mL

Results: The oxysensor was introduced without any problem in the majority of parturients (42/44) and minor adjustment were made to sensor placement when SpO_2 readings were not displayed on the monitor The duration of monitoring varied between 370 min to 34 min and the sensor gave adequate recordings in 74% (range 32–100%) of registration time The mean SpO_2 averaged throughout the first stage of labor was 50% (sd 10) and for each individual fetus SpO_2 values were relatively constant A transient reduction of SpO_2 was noted during uterine hypertonus due to maternal administration of oxytocin or maternal hypotension, in the presence of reactive FHR trace and normal outcome In two cases a stable reduction of SpO_2 (<20%) during end-stage decelerations was noted and associated with forceps delivery, neonatal acidosis and poor Apgar scores at delivery In three cases a cesarean section under epidural anesthesia was performed for failure to progress (n = 1) or for not reassuring FHR tracing (n = 2) and we were able to make a continuous measurement of fetal SpO_2 during the onset of epidural block and during surgery until the delivery of the baby. In these cases was noted, during the onset of epidural block, a trend toward an increase of SpO_2

Conclusions: There was no measurable effect on fetal SpO_2 following an uneventful epidural analgesia Epidural anesthesia for cesarean section may improve fetal SpO_2 Further studies on correlation between FHR changes and fetal SpO_2 during epidural anesthesia are in progress.

A.519 A large randomized controlled trial comparing epidural bupivacaine with intramuscular pethidine for pain relief in labour in primiparous women

B.A. Loughnan, F Carli, M Romney, C Dore, H. Gordon *Departments of Anaesthesia and Obstetrics, Northwick Park Hospital MIDDX HA1 3UJ, England*

Background and Goal of Study: Epidural analgesia may increase the likelihood of obstetric intervention Previous randomised studies have been small and were not analysed on an intention to treat basis [1] This randomised controlled trial examines the effect of epidural analgesia on obstetric outcome.

Methods: Following local Ethical Committee approval, written informed consent was obtained from 797 primigravidae in the later stages of uncomplicated pregnancy. Only women uncommitted to any particular form of analgesia were recruited

On admission to delivery suite in established labour, 164 women declined their randomised treatment, and 190 women required entonox only. Of the 633 women who required analgesia, 321 were randomly allocated to receive pethidine 100 mg by intramuscular injection and 312 to receive epidural bupivacaine 10–15 ml 0 25% followed by an infusion of 0 125% bupivacaine at 10 ml. Hr^{-1} with top-ups of bupivacaine 0 25% 5 ml as required. The management of labour was standardised according to the criteria for the active management of labour[2]

Pain relief scores were assessed 24 hour after delivery by the mother on a 5 point scale (excellent, good, moderate, poor, very poor). Outcomes of labour measured included the duration of the 1st and 2nd stage of labour, whether oxytocin augmentation was required and mode of delivery. Statistical analysis was performed on an intention to treat basis using Mann Whitney U test, t test and Fisher's exact test as appropriate. We also compared the groups on the basis of treatment received.

Results and Discussion: 132 women in the pethidine group (41%) required an epidural for uncontrolled pain. The intention to treat analysis showed caesarean section rates identical in both groups (12%). There no difference between the groups in other modes of delivery or syntocinon administration. When analysis was performed on the basis of treatment received, there was no significant difference in caesarean section rate but the epidural group had a significantly lower spontaneous vaginal delivery rate (56% vs. 69%, $p = 0.005$) and a longer duration of second stage ($P < 0.001$). Mothers receiving epidural analgesia rated their analgesia higher than those receiving pethidine ($P < 0.001$)

Conclusions: Our results suggest that epidural analgesia does not result in a significantly higher rate of caesarean section or instrumental delivery.

A.520 Effect of the addition of a mini dose of clonidine to intrathecal sufentanil for labour analgesia

L Saltel, C. Cabiro, M. Cesarini, M. Mekki, J. Lichay, R. Torrielli
Department of Anaesthesia-Reanimation IV Maternité de Pellegrin, 33076 Bordeaux cedex, France

Background: Intrathecal (IT) sufentanil 5–10 μg provides good analgesia. The addition 30 to 200 μg of clonidine prolonges IT sufentanil duration but increases incidence of hypotension (1, 2). Goal of study was to evaluate the analgesic efficacy and the side effects of IT sufentanil combined with 15 μg of clonidine during first stage labor.

Methods: 90 parturients, ASA 1–2, para 0–1, cervical dilatation ≤ 5 cm, were enrolled. Patients were assigned to receive through a combined spinal-epidural (CSE) needle, one of the intrathecal solution in 2 ml of saline: sufentanil 2.5 μg (S2.5); sufentanil 5 μg (S5); sufentanil 2.5 μg and Clonidine 15 μg (S2.5 C15). Duration of IT analgesia was defined as the time between IT injection and the need for epidural bupivacaine analgesia. Analgesic efficacy was assessed with a VAS was recorded before the CSE (VAS 0), at 5 min (VAS 5) and at 15 min (VAS 15) after IT injection, and the peridural injection of bupivacaine (VAS max). Total dose of bupivacaine was recorded. Hypotension was defined as a SBP < 95 cm Hg and/or a decrease >20% from baseline. Parameters recorded were: non invasive blood pressure and heart rate ephedrine requirement, motor block, respiratory rate, SpO_2, sedation, pruritus, nausea, FHR anomalies, mode of delivery. Data are expressed as mean ± DS, groups were compared with and ANOVA and Fisher'exact test. $P < 0.05$ was considered significant.

Results:

	S2.5 (n = 30)	S5 (n = 30)	S2.5 C15 (n = 30)
Analg (min)	90 ± 28*	122 ± 67	133 ± 45
VAS 0	7 ± 2	7 ± 2	7 ± 2
VAS 5	2 ± 2.3	0 ± 0.8*	1 ± 2
VAS 15	0	0	0
VAS max	5 ± 1.8	5 ± 2.1	5 ± 2
Bupi (mg)	65 ± 42	68 ± 35	54 ± 25

* $p < 0.05$ vs other groups

The incidence of hypotension (30 vs 3%) and the ephedrine requirement were increased in gr S2.5 C15. No patient had any motor block. The incidence of cesarean was doubled in group S2.5 C15 (20% vs 10%). There was no statistically significant difference among other parameters but nausea and sedation were more frequents in group S2.5 C15.

Conclusion: The association of low dose clonidine improves the analgesic efficacy of IT Sufentanil. However the incidence of hypotension is increased. Doubling IT sufentanil (2.5 to 5 μg) produced a significantly longer duration of spinal analgesia without hemodynamic effects.

A.521 Parturient-controlled epidural analgesia: the advantages of programming volume limit per hour

D. Bresard[1], F Nemoz[1], D. Goumard[2], J. Fusciardi[1] [1]*Department of Anaesthesiology, University Hospital of Poitiers, 86021 Poitiers,* [2]*Department of Anaesthesiology, Saint Louis Hospital, 17000 La Rochelle, 17000 La Rochelle, France*

Controlling the maximum volume per hour (MVH) enables for a given bolus volume (B.PCEA) a shortening of the lock-out interval (LI) while limiting maximum volume. The aim of this study was to compare two different PCEA modes, each having identical B.PCEA and MVH, but differing LI's.

Methods and Materials: 94 parturients were selected. Only those at full term, ASA1, with cephalic presentation were included in this randomised two centre study. PCEA procedure consisted of 1) one Abbott MENAGER pump, 2) 42 ml of solution comprised of. bupi. 1.25 mg/ml sufentanil 0.75 μg/ml; epinephrine 1.25 μg/ml, 3) a 10 ml initial bolus, 4) 4 ml B.PCEA, 5) 12 ml MVH. After an effective initial analgesic bolus (EVA = 0), parturients were randomly placed into one of the two groups· group A with LI at 20 mn (n = 47), group B with LI at 10 mn and if needed, the possibility of lengthening LI to maintain appropriate MVH (n = 47). Residual pain (EVA ≥ 5) was treated with additional boluses (ADB) of bupi 0.25% or 0.375%. Analysis criteria were the ratio of the nb of B.PCEA to the nb of requests (B/D), the average nb of B.PCEA, average number of ADB, bupi. time-dose and the proportion of ADB (bupi.ad), sufentanil time-dose, EVA, satisfaction at 24 hours. The tests utilised were· Student's t-test and the chi-2.

Results: In the two groups, demographic, obstetric, neonates, analgesic procedures in time and quality as well as 24 h satisfaction were all comparable. Utilisation modes were different (table).

	Group A n = 47	Group B n = 47	p
B/D	0.74 ± 0.27	0.94 ± 0.10	<0.0001
B PCEA. nb	2.72 ± 1.85	3.53 ± 1.88	0.038
B ad. nb	0.46 ± 0.62	0.21 ± 0.41	0.021
Bupi mg/h	9.25 ± 4.28	8 ± 2.42	0.065
% Bupi.ad	18.1 ± 23.1	7 ± 13.7	0.007
Suf μg/h	4.14	4.42	0.32

Discussion and Conclusion: Given the comparable bupi consumption, identical analgesia and satisfaction, the PCEA return is better in group B since 94% of requests are satisfied. With this improved return, we are able to limit the number of ADB. MVH control may be more simply by programming decreased volume limit per hour if available on device rather than by secondary LI modifications such as in the case of our study.

A.522 Intrathecal bupivacaine reduces uterine activity in labouring and non gravid rats

P. Malassiné[1,2], G Germain[1], J. Seebacher[2], J. Rousseau[1], P Conat[2]
[1]*Laboratoire de Neurobiologie des Fonctions Végétatives, INRA, 78352 Jouy-en-Josas cédex;* [2]*Dept. d'Anesthésie-Réanimation, Hôpital Pitié-Salpêtrière, 75651 Paris cédex 13, France*

Background and Goal of Study: Loco regional analgesia can reduce uterine activity in parturient [1] and dog [2]. The aim of our study was to evaluate the effect of intrathecal (IT) 0.25% bupivacaine (BUPI) on uterine activity in labouring (G) and non gravid rats (NG)

Materials & Methods: 4 groups of 6 female Sprague-Dawley rats received IT: normal saline (Control Groups G and NG) or BUPI (groups BUPI, G and NG). Under ketamine anaesthesia and mechanical ventilation, arterial pressure (AP), intravenous (IV), IT (located between L1–L2 and L3–L4 nerve roots), and intrauterine pressure (IUP) catheters, and temperature (T) probe were implanted. After a baseline period of 20 min, 3 cumulative IT doses of BUPI (10, 10, and 20 μl) or saline were injected, followed by a recording period of 20 min. AP was maintained constant (iv starch loading). Data are mean % of baseline ± SD. Repeated-measure ANOVA was used.

Results: IUP changes are given in Figs. 1 et 2. No significant variations in AP and T were noted.

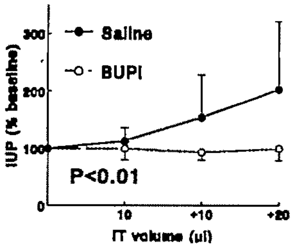

Figure 1. IUP in G rats

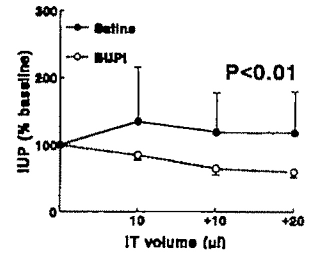

Figure 2 IUP in NG rats

Conclusion: Our results suggest that IT BUPI reduces uterine activity both in NG and G rats

A.523 Current management of inadvertent dural taps occurring during epidural analgesia for pain relief in labour: a French postal survey

V Souron, L Simon, P. Sacquin, J. Hamza. *Dépt d'Anesthésie-Reanimation, Hôpital St Vincent de Paul 74-82, av. Denfert Rochereau, 75014 Paris, France*

Background and Goal of Study: According to a survey in the United Kingdom, management of dural taps occurring during epidural analgesia (EA) in labour varies widely from an institution to another (1). The different measures to manage inadvertent dural taps before and after postdural puncture headaches (PDPH) are still controversial. As the routine prophylactic and curative treatment in France is unknown, we designed a questionnaire that was sent to all french obstetric units to survey this practice.

Materials and Methods: From april to june 1997, a questionnaire including 22 items was sent to 799 french obstetric units located in both teaching and not teaching public hospitals and private institutions.

Results and Discussion: We received answers from 267 french obstetric units (response rate of 33.4%) Although management of dural taps was the same for every anesthesiologist in 52.4% of the institutions, only 8.2% had a written protocol In case of dural puncture, EA was still performed by 94.9% of the units but usually by choosing another interspace (86.8%). Large oral intake was the most frequent prophylactic measure (81.3%) To prevent PDPH, bed rest was largely ordered (76.4%) and lasted 24 hours in 46.5% of institutions. Prophylactic epidural blood patch (EBP) was performed in 13 4% of the obstetrical units. To treat PDPH, a majority of anesthesiologists performed an EBP (91 8%) and most of them respected a delay of 48 hours (62.5%). Intravenous and oral caffeine was used by 30 7% and 23.6% of the units. Prior to EBP, coagulation was assessed in about 20% of the units and blood culture in only 2.6%. 65 2% of the units stopped the injection of EBP when the patients felt backache A large range of volumes were injected but usually less than 20 mL (81 3%). 60.6% of the units discharged the patients home after an overnight stay in the hospital. If the first EBP failed, a second one was performed by 60 7%. The feeling of the anesthesiologists about performing an EBP is shown in fig. 1

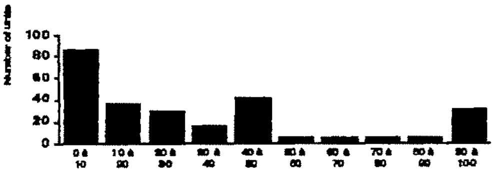

Fig 1. Distribution along analogue scale-personnel feeling about performing EBP (0 = happy/100 = unhappy) n 267

Conclusion: Management of dural taps occurring after EA for pain relief in labour differs widely from a french obstetrical unit to another Comparing with the practice in the United Kingdom (1), the main differences are: not so many protocols, no use of epidural saline infusions and larger use of caffeine

A.524 Obstetric analgesia as a guide to progress of labour. Is it possible?

N Sáiz-Sapena, A Macías, A. Sáez-Fernández, R. Zarauza, R. Calderón, M Adame *Department of Anaesthesiology, University Clinic, School of Medicine, University of Navarra, Spain*

Background & Goal of Study: Obstetricians are aware that a deep regional anaesthesia can at times interfere with the progress of labour and delivery That is why many of them still lack confidence about the real advantages of regional anaesthetic techniques It would be ideal to get a protocol that fits everyone: effective enough for the parturient, and with full agreement from the obstetrician We have developed an analgesic protocol that, being well followed by the staff and well accepted by the parturients, is also helpful for midwifes and obstetricians to know about the progress of labour.

Patients & Methods: In the last five years we have tested a combination of different local anaesthetics, concentrations, adjuvants, and perfusion rates, in order to minimally affect the progress of labour, and at the same time have a guidance about it. We selected the one that best fitted our aim, and prospectively applied it when possible.

Selected patients were those pregnant women in labour, scheduled for epidural analgesia having a cervical dilatation of 3–5 cm or in trial labour under oxytocin stimulation. After the epidural space was identified, 2 cc mepivacaine 1% was administered through the Tuohy needle The catheter was inserted and another 2 cc mepivacaine 1% administered Then a local anaesthetic perfusion was started, containing bupivacaine 0.0625% + epinephrine 1:800.000 + fentanyl 0 0002% The perfusion rate was adjusted according to the cervical dilatation (i e 4 ml/h for 4 cm cervical dilatation and so on). When the patient started to feel discomfort, a bolus of 2 cc of the perfusion solution was administered and a higher rate initiated The anaesthesiologist survey was continuous, to adapt the perfusion rate to the needs of the patients.

Results & Discussion: With the protocol described we observed that the dose of analgesia the patients needed was directly related with the cervical dilatation, in such a way that the needs of analgesia could guide the midwifes about the progression of labour. The analgesic needs were 20% higher in the cases of trial labour under oxytocin The perfusion and doses described were analgesic enough, without reducing aesthesia in lower limbs as to be unpleasant Patient satisfaction with labour assistance (pain, environment, people) was qualified as very good in more than 90% cases, what at some extent we attribute this fact to the high confidence of the patient when she feels coordination and understanding in the obstetrical-anaesthetic team. What is more, midwifes collaboration was excellent They qualified this protocol also as excellent, because they found it very useful for their practice. Since the perfusion rate was so related to the cervical dilatation, the number of gynaecological examinations was also reduced.

Conclusions: The analgesic rate of a perfusion of bupivacaine 0 0625% + epinephrine 1 800.000 + fentanyl 0.0002% to be analgesic enough is directly related to the cervical dilatation (1 ml/h per cm dilatation, plus a 20% in trial labour under oxytocin). In our hands his has proved to be a very useful guidance about labour progression

A.525 Combined spinal-epidural analgesia in labour: comparison of two doses of intrathecal bupivacaine with fentanyl

B B. Lee, W.D Ngan Kee. *The Chinese University of Hong Kong, Prince of Wales Hospital, Hong Kong, China*

Background and Goal of Study: Combined spinal-epidural (CSE) analgesia is an effective and popular method of labour analgesia[1] Local anaesthetic is frequently added to intrathecal opioid. However, this may cause undesired sensory and motor block, and the optimum dose is not known. We compared two doses of bupivacaine with 25 μg fentanyl

Materials and Methods: In a prospective randomized double-blind trial, 50 parturients were assigned to receive either 1.25 mg bupivacaine (Gp A) or 2.5 mg bupivacaine (Gp B), with 25 μg fentanyl, intrathecally during CSE analgesia Baseline visual analogue pain score (VAPS) was taken at the peak of a uterine contraction. After intrathecal injection, VAPS were recorded at 5-min intervals for 15 min, then every 15 min for 2 hr or until next analgesic request Sensory block, motor block, BP, HR, sedation, nausea, and pruritus were also recorded Data were analyzed using Chi-square and Mann Whitney-U tests. $p < 0\ 05$ was considered significant.

Results and Discussion: 45 patients completed the study (Group A = 21, Group B = 24). There were no differences in patient characteristics. Median VAPS of 0 was achieved by 5 min in both groups Both sensory and motor block were significantly greater in Group B. Other side effects were similar.

	Group A	Group B	p-value
Median sensory level (15 min)	T11	T6	0 002
Motor block (15 min)	Yes (n = 0) No (n = 21)	Yes (n = 6) No (n = 18)	0 0138
Median duration of analgesia (interquartile range)	75 min (75, 105)	113 min (90, 120)	0.017

Conclusions: We recommend using 1 25 mg bupivacaine intrathecally during CSE as it is as effective as 2 5 mg, with lower incidences of sensory and motor block.

A.526 Thermoregulatory response during labour, with and without epidural analgesia

O.P.F. Panzer[1], N. Ghazanfari[1], M. Greher[1], A Donner[1], P. Germann[1], Y. Yucel[2], D I Sessler[3], A. Kurz[1]. *Department of [1]Anesthesia and [2]Obstetrics, [3]University of California, San Francisco, USA, University of Vienna, Austria*

Background: Shivering-like tremor and sweating are common during labour and delivery Their etiology, though, remains unclear One potential cause of shivering-like tremor is normal thermoregulatory shivering induced by core hypothermia or skin-surface cooling, and is preceded by peripheral vasoconstriction. On the other hand, thermoregulatory sweating occurs as a result of core hyperthermia which is preceded by vasodilation. However, both, shivering and sweating can sometimes occur in normothermic subjects as well. Non-thermoregulatory mechanisms such as pain, stress, and endocrinological responses during pregnancy might explain this phenomenon. Furthermore, shivering etiologies might differ when epidural analgesia is provided. Accordingly, we evaluated thermoregulatory response patterns during labour in delivery, with and without epidural analgesia

Methods: With IRB approval, we studied 40 consenting patients undergoing normal labour and delivery. Twenty-one patients were given epidural analgesia (bupivacaine 0.125%, 10–15 ml bolus, 0.125%, 0.1–0.2 mg/kg/h continuous infusion) The remaining group (n = 19) either had no pain medication or received a bolus dose of piritramid (0.1 mg/kg PRN).

Thermoregulatory responses were recorded at 30-minute intervals until two hours after normal delivery, or until a cesarean delivery was required. Mean core temperature was measured orally, and at the tympanic membrane. Arterio-venous shunt vasomotion was evaluated by using forearm minus fingertip skin temperature gradients Shivering and sweating were evaluated using a qualitative scale from 0 to 2 Thermal discomfort as well as pain were recorded using a 100 mm-long VAS. Data were analyzed (referring to the total number of epochs) using unpaired two-tailed t-test and $p < 0.05$ was considered significant

Results: Sweating was observed in 26% of the whole (312) epochs At 14% of the sweating epochs, patients were surprisingly hypothermic (36.3 ± 0.2°C) and vasoconstricted Shivering was observed in 23% of all epochs. Interestingly, 18% of shivering epochs was observed when the patients were normothermic (37.4 ± 0.8°C), and vasodilated At 9% of the epochs, shivering and sweating were observed at the same time in normothermic subjects (37.1 ± 0.6°C). In this group, the average pain score was found as 81 ± 20 In the epidural analgesia cases, average core temperature was found to be 0.5°C higher than the group without epidural analgesia.

Conclusion: At both, shivering and sweating epochs, the pain scores were significantly higher than the remainders. At the epochs where shivering and sweating were observed at the same time, pain seemed to be the major cause. We observed many shivering and sweating epochs which were not thermoregulatory. These extraordinary responses might be explained by pain or/and endocrinological processes occurring during labour and delivery.

INTENSIVE CARE MEDICINE

A.527 Effect of endothelin-1 on LPS clearance and bacterial killing in rabbits

T. Koch, S. Heller, A. Heller, T.-L.-H. Phan, J. Schmeck, R. Urbaschek.
Dept. of Anaesthesiology and Operative Intensive Care Medicine, Faculty of Clinical Medicine Mannheim, University of Heidelberg, FRG

Introduction: The vasoactive peptide endothelin-1 (ET) seems to play a key role in inflammation via interaction with the release of cytokines, the generation of eicosanoids, and NO synthesis [1]. Since LPS is one potent trigger of ET-synthesis in various tissues, the aim of this study was to investigate whether ET affects host defence mechanisms such as LPS clearance and bacterial killing in rabbits.

Methods: To enable quantification of the clearance process, a defined number of viable *Escherichia (E.) coli* (10^8 CFU) were injected intravenously in anaesthetised rabbits after infusion of ET (n = 9) and in untreated controls (n = 9) respectively. Mean arterial and airway pressures were continuously monitored. To evaluate bacterial and LPS clearance, blood samples were drawn in short intervals. 180 min after bacterial injection, the animals were sacrificed and tissue samples of liver, kidney, spleen, and lung were collected for microbiological examinations.

In addition PMN, burst and phagocytic activity was determined in a flowcytometric assay to assess neutrophil microbicidal functions

Results: ET-infusion resulted in a higher MAP and airway pressure during the observation period While blood clearance of *E. coli* and LPS in ET challenged animals did not significantly differ from controls, there was an increased extrahepatic organ colonisation due to ET-infusion with fourfold higher bacterial counts in spleen and lung and a twofold increase in the kidney. PMN burst and phagocytic activities were currently evaluated

Conclusion: The increased organ colonisation after ET-infusion points towards an impaired host defence against microbial infections. Whether these effects may be related to disturbances in the microcirculatory blood flow remain to be elucidated

A.528 Effects on platelet function of systemic inhibition of endogenous nitric oxide production by L-NMMA

J. Albert, H. Wallén, N. Li, C. Frostell, P. Hjemdahl *Dept. of Anesthesiology, and Dept. of Clinical Pharmacol, Karolinska Institute at Karolinska Hospital, Stockholm, Sweden*

Background: Endogenous nitric oxide (NO) produced by endothelial cells has been shown to act as a continuous vasodilator of the circulatory system. *In vitro* studies have also indicated that NO produced by endothelial cells inhibit platelet function Animal studies have indicated that inhibition of NO production has prothrombotic effects and that endogenous and exogenous NO may have antithrombotic effects. Septic chock is in part mediated by increased NO production, and treatment of septic shock with N^G-monomethyl-L-arginine (L-NMMA), an inhibitor of endogenous NO, is being evaluated in clinical multicenter trails

Material and Methods: We have studied the effects of L-NMMA on platelet function *in vivo* in healthy volunteers during a 60 min infusion (n = 14) During the last 30 min concomitant inhalation of NO 30 ppm was given. The study design was randomised double-blind, placebo-controlled cross-over trial for L-NMMA (0.3 mg/kg/min for 30 min, followed by 0.15 mg/kg/min for 30 min). This dose of L-NMMA suppressed NO in nasal air by ≈65% in a previous study. Platelet function was assessed by filtragometry *ex vivo*, flow cytometry in whole blood (P-selectin expression and fibrinogen binding), measurements of platelet secretion products (β-TG) in plasma and bleeding time. In addition, thrombin generation markers (TAT, F1 + 2), and cGMP in plasma and platelets were measured.

Results: L-NMMA infusion increased systolic blood pressure by 24% ± 7% and decreased heart rate Plasma cGMP was not influenced by L-NMMA, but increased significantly during NO inhalation (from 4.00 ± 0.48 to 12.19 ± 0.86 and from 3.97 ± 0.32 to 9.23 ± 0.57 during L-NMMA and placebo, respectively, $p < 0.001$); no changes in platelet cGMP could be found. Neither platelet aggregation measured with filtragometry *ex vivo*, nor P-selectin expression or fibrinogen binding (to GPIIb-IIIa receptors) or plasma β-TG revealed significant changes, either during L-NMMA or during NO inhalation. Plasma TAT and F1 + 2 were stable. Bleeding time increased following NO inhalation ($p < 0.001$), and this effect was similar in L-NMMA and placebo experiments (24% during L-NMMA, and 28% during saline)

Conclusion: Inhibition of NO synthesis by L-NMMA had no significant effects on platelet function despite clear-cut effects on blood pressure. The addition of NO inhalation had no effects on platelet function measured with several different techniques, apart from a slight increase of bleeding time, both during L-NMMA and placebo infusions

A.529 LPS does not induce changes in hepatocellular microtubule cytoskeleton and phosphorylation of MAP-kinases

S. Russwurm, M. Wiederhold, K.J. Böhm[1], P. Mühlig[1], I. Stonans;
E. Unger[1], K. Reinhart. *Department of Anesthesiology and Intensive Therapy; [1] Institute of Clinical Immunology, Friedrich-Schiller-University of Jena, D-07740 Jena, Germany*

Introduction: Lipopolysaccharides (LPS) are known to be involved in the pathogenesis of septic shock and multiorgan failure. It has been demonstrated that LPS may cause changes in monocyte cytoskeleton and directly influence assemblation of isolated microtubuli. As liver failure is increasingly observed during septic shock we estimated the influence of LPS on microtubule cytoskeleton of cultivated hepatocytes and human blood monocytes.

Methods: HepG2 cells, murine hepatocytes, or human monocytes (positive control) were incubated with LPS FITC labelled or unlabelled (0.1–200 µg/ml) up to 48 h. After staining with antibodies to tubulin and tau proteins cells were analysed by fluorescence and laser scan confocal microscopy. Activation of MAP-kinases was investigated by Western Blot using phosphospecific antibodies.

Results: Immunofluorescence revealed that the cytoskeleton of hepatocytes was not affected by LPS. Furthermore, no phosphorylation of MAP-kinases was found after LPS-incubation Mouse hepatocytes and HepG2 cells did not accumulate FITC labelled LPS. In contrast, human blood monocytes showed an accumulation of FITC-LPS, an activation of MAP-kinases and changes in microtubule cytoskeleton.

Conclusions: Our results might explain the frequently observed late onset of liver failure during sepsis-syndrom. Further studies on possible protective factors in hepatocytes and the complex co-operation between LPS and cytokines leading to hepatocellular damage are necessary.

A.530 Human peripheral blood mononuclear cells express mRNA for procalcitonin

M Oberhoffer, S. Russwurm, I. Stonans, E Stonane[1], U Junker[1], H Vogelsang[1], L Jager[1], K Reinhart *Department of Anesthesiology and Intensive Therapy, [1]Institute of Clinical Immunology, Friedrich-Schiller-University of Jena, D-07740 Jena, Germany*

Introduction: Procalcitonin (PCT), the precursor of calcitonin, is produced under physiological conditions in the thyroid It was recently identified as a marker of severe especially bacterial infection. Elevated PCT levels have been demonstrated in septic patients also after thyroidektomy Therefore other sites of PCT expression have to be considered.

Methods: Possible PCT mRNA expression in peripheral blood mononuclear cells (MNC) from healthy humans was assessed by reverse transcriptase polymerase chain reaction (RT-PCR) using a novel primer set (B R A H M S, Berlin). Levels of PCT mRNA expression were estimated in control and cultures of MNC stimulated by lipopolysaccharides (LPS) and sepsis related cytokines. Restriction mapping was performed to verify the specificity of PCR primers for human PCT by digestion of PCR amplified thyroid medullary carcinoma cDNA

Results: RT-PCR analysis demonstrated that MNC express mRNA for PCT and that LPS as well as various cytokines may modulate this expression In the cultures stimulated with LPS from E. coli B4 and Salmonella abortus equi the final RT-PCR product for PCT mRNA was elevated up to 200% to 2300% in comparison with 100% in control culture. Pronounced effects were also observed for IL-1β – 100–1800%, IL-6 – 200–3500%; TNF-α – 200–9000%; IL-2 – 250–1500%. IL-10 had no effect on the expression of mRNA for PCT.

Conclusions: We demonstrate for the first time that PCT is expressed in MNC This expression is modulated by bacterial LPS and sepsis related cytokines Therefore MNC may be one of the sources for elevated plasma PCT levels in septic patients

A.531 Effects of L-NAME on PMN-function and bacterial clearance in rabbits

S Heller, J Weikel, A. Heller, J Schmeck, R Urbaschek, T. Koch *Dept. of Anaesthesiology and Operative Intensive Care Medicine, Dept. of Med Microbiology, Faculty of Clinical Medicine Mannheim, Univers of Heidelberg, FRG*

Introduction: Since the release of NO has been shown to play an important role in the vasoregulation during sepsis the use of nitric oxide synthase inhibitors was investigated in different animal models Aim of this study was to investigate, whether pretreatment with the inhibitor of nitric oxide synthase N-nitro-L-arginine-methylesther (L-NAME) affects host defense mechanisms against microbial infections. For this purpose bacterial clearance from the blood and tissues as well as PMN phagocytosis and burst activity were determined in anesthetized rabbits.

Methods: To evaluate potential effects of L-NAME on bacterial elimination and killing, blood-clearance of Escherichia (E.) coli and organ colonization were investigated in anesthetized rabbits after pretreatment with L-NAME (5 mg/kg b.w./h, n = 14) and in sham operated animals (controls, n = 14) respectively To enable quantification of the clearance process, defined numbers of exogenous E coli (10^8 CFU) were injected intravenously 60 min after the beginning of L-NAME application To characterize elimination kinetics of injected *E. coli*, blood samples were drawn for bacterial counts in short intervals Samples of liver, lung and kidney were collected 180 min following *E coli* injection, to assess organ colonization. Parameters monitored were rates of bacterial elimination from the blood, arterial pressure, blood gases and white blood cell counts 180 min after bacterial injection tissue samples of liver, kidney, spleen and lung were collected for microbiological examinations PMN phagocytosis and burst activity were determined using a flow cytometric assay Differences between groups were tested by ANOVA and subsequent multiple range test (LSD)

Microbiological Results: Compared with controls, L-NAME treatment resulted in a significantly prolonged bacterial clearance process with higher E coli concentrations in the blood ($p < 0.05$). The delayed blood-clearance was associated with significantly ($p < 0.01$) higher values of bacteria in liver, lung and kidney

Flow-cytometric Results: Pretreatment with L-NAME reduced significantly the PMN-phagocytosis ($p < 0\ 05$) but enhanced oxygen radical production

Conclusion: The impaired bacterial elimination from the blood and the enhanced organ colonisation in relation to the reduced PMN-phagocytosis point towards an impaired granulocyte dependent bacterial clearance function after pretreatment with L-NAME, thus predisposing the host to increased risk of infection.

A.532 Distribution of microcirculatory blood flow in the gastrointestinal tract during haemorrhagic shock

V. Krejci[1], D. Erni, A Banic, A Wheatley, G H Sigurdsson[1]
[1]Departments of Anaesthesia & Intensive Care Medicine, Plastic & Reconstructive Surgery, Visceral & Transplantation Surgery, Inselspital University Hospital of Berne, 3010 Berne, Switzerland

Background: Hypoperfusion of splanchnic organs after hemorrhagic shock may cause severe complications such as multiple organ failure The intestinal mucosa is very vulnerable to ischemia due to a particular microvascular arrangement of the villi and high oxygen consumption of the mucosal cells that leads to low pO 2 at the villus tip even during normal blood supply. Little is known about dynamic flow-distribution within the splanchnic region in circulatory shock Recently a multichannel laser Doppler system has become available that can measure microcirculatory flow (MCBF) in multiple organs simultaneously and continuously (incl the intestinal mucosa)

Methods: Eight pigs were anesthetised and ventilated MCBF was measured in the intestinal mucosa (stomach, jejunum, colon), pancreas, liver and kidney using a six-channel laser Doppler flowmeter system Systemic hemodynamics (CI, MAP etc), superior mesenteric artery flow (SMA flow, TTF) and gastric mucosal pH (pHi, tonometry) were also measured After preparation, the animals were bled to MAP of 40 mmHg during 30 min and kept at 40 mmHg for 180 min before retransfusion of shed blood and fluids

Results: The main results are summarized in the table

Relative changes to baseline (mean ± SD)	Baseline t = 0 min	After blood loss t = 30 min	Before retransfusion t = 180 min	After retransfusion t = 210 min	After retransfusion t = 330 min
CI	100	53 ± 15	55 ± 14	99 ± 42	107 ± 32
MAP	100	43 ± 8	42 ± 8	73 ± 19	71 ± 15
SVR	100	85 ± 14	77 ± 18	78 ± 29	69 ± 19
SMA flow	100	68 ± 14	85 ± 21	153 ± 94	133 ± 37
LDF Stomach	100	65 ± 27	72 ± 28	114 ± 45	120 ± 44
LDF Jejunum	100	94 ± 15	101 ± 32	129 ± 43	115 ± 30
LDF Colon	100	84 ± 24	77 ± 29	124 ± 38	109 ± 19
LDF Pancreas	100	41 ± 14	39 ± 16	81 ± 43	80 ± 45
LDF Liver	100	71 ± 21	57 ± 36	71 ± 26	82 ± 36
LDF Kidney	100	70 ± 20	63 ± 25	124 ± 99	141 ± 98
pHI	7 23 ± 0 06	7 20 ± 0 08	7 13 ± 0 07	7 17 ± 0 04	7 19 ± 0 07

Discussion: During shock, mucosal flow in the stomach and colon decreased by 15–30%, similar to the SMA flow, while the jejunal flow remained virtually unchanged Flow in the liver and kidney decreased somewhat more (30–40%), but flow in the pancreas was most severely affected (decreased by 60%) After retransfusion of shed blood SMA flow increased by 30–50% and mucosal flow (stomach, jejunum, colon) by 10–30% as compared with baseline Although microcirculatory flow in the pancreas and liver increased slightly after retransfusion it remained significantly depressed (20–30% below baseline)

Conclusion: During hemorrhagic shock and after fluid volume resuscitation there was a considerable difference in microcirculatory flow changes in the various parts of the gastrointestinal tract studied The jejunal mucosa was the least severely affected (remained unchanged) while the pancreas was most the most severely affected organ studied with 60% decrease in microcirculatory flow during shock.

A.533 Tissue hypoxanthine reflects splanchnic vulnerability in porcine endotoxin shock

Anders Oldner, Michael Wanecek, Michel Goiny[1], Anders Rudehill, Urban Ungerstedt[1], Alf Sollevi. *Dep Anaesthesia & Intensive Care, Karolinska Hospital; [1]Dep. Pharmacology & Physiology, Karolinska Institute, Stockholm, Sweden*

Background & Goal of Study: The splanchnic region has been reported as specifically vulnerable during shock states[1–3]. In this study we evaluated potential interorgan differences in interstitial hypoxanthine, a metabolite of ATP degradation and cellular energy failure, during progressive endotoxin shock in the pig.

Materials & Methods: Seventeen pigs were anaesthetised and catheterised. Tissue levels of hypoxanthine, assessed by in vivo microdialysis (human probe 30 mm, CMA, Sweden), were monitored in several organs (ileum, liver, lung, skeletal muscle, subcutaneous fat and arterial blood) simultaneously in addition to central hemodynamics. Ten pigs were subject to endotoxemia (20 $\mu g \cdot kg^{-1} \cdot min^{-1}$) while seven sham animals served as controls The experiments were terminated 5 h after onset of endotoxemia

Results & Discussion: Tissue hypoxanthine and hemodynamics proved to be stable in the sham group while marked changes were seen in central hemodynamic parameters in response to endotoxemia. The most prominent increase in hypoxanthine was seen in the ileum (277% of baseline at 5 h) while only limited changes were observed in skeletal muscle and fat Intermediate increases were seen in the liver, lung and arterial blood. These results indicate a differentiated development of ATP degradation and cellular energy failure in response to endotoxemia in different organs Considering the high amounts of xanthine oxidase seen in the gut the increases in hypoxanthine may provide an important substrate for reactive oxygen species formation in these organs. Furthermore, these results suggest that microdialysis in subcutaneous fat commonly used in the clinical setting may prove to be of limited sensitivity during septic conditions

Conclusion: These findings support previous reports of specific vulnerability of the splanchnic organs during endotoxemia.

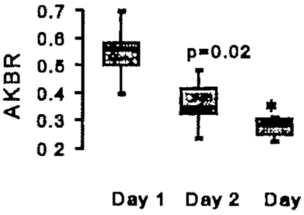
A.534 Mitochondrial redox state in septic shock

K. Yassen, H.F. Galley[1], A. Lee, N R Webster[1] *Department of Anaesthesia, Royal Infirmary of Edinburgh; [1]Academic Unit of Anaesthesia, Aberdeen University, UK*

Background and Goal of Study: Patho-physiological changes occurring as a result of severe infection may poison normal intracellular metabolic processes. There is much interest in measurement of arterial ketone body ratio (AKBR), the ratio of acetoacetate to 3-hydroxybutyrate in patients with sepsis as a marker of mitochondrial redox state Aim is to investigate AKBR and plasma lactate in critically ill patients with and without septic shock, and to assess their usefulness as indices of clinical status.

Materials and Methods: Patients were enrolled into the study following Ethics Committee approval and patient consent. Ten patients fulfilled the Consensus Conference Criteria for sepsis. Ten non-infected APACHE II matched control patients were also studied. Blood samples were taken after an intravenous bolus administration of 15 g glucose (to suppress ketogenesis). Sampling was repeated at 24 and 48 hrs. AKBR was measured using the Ketorex C Kit (Genzyme Diagnostics). Data expressed as median and range and compared by using Mann Whitney U test or Kruskal-Wallis analysis of variance.

Results: Six (60%) patients died in the septic group and 3 patients (30%) died in the control group. AKBR decreased over the 3 days in the septic patients who died ($p = 0.002$, Figure) and AKBR was lower on day 3 in these patients compared to survivors ($p = 0.019$). AKBR in non-septic controls did not change and was not different from septic patients. However, AKBR in all patients was lower on day 3 in those who died than in survivors ($p = 0.002$).whether septic or non-septic Lactate did not change over the 3 days in any group, but the lactate concentrations were higher in non-survivors on day 3 than in survivors, in septic ($p= 0.01$), non-septic ($p = 0.017$) and all patients ($p = 0.002$). Lactate correlated negatively with AKBR on day 3 ($r = -0\ 53$, $p = 0\ 015$)



Conclusion: Decreased AKBR and increased lactate concentration were associated with non-survival in critically ill patients, especially with sepsis: Serial AKBR could be useful to assess effectiveness of therapeutic interventions

A.535 Role of the liver in interleukin-10 production in a porcine model of endotoxicosis

B. Ickx, C.E Velghe-Lenelle, S. Pierre, J. Closset, V Donckier, M. Goldman, A. d'Hollander. *Service d'Anesthesiologie-Réanimation, C.U.B. Erasme, Bruxelles, Belgium*

Background and Goal of Study: Sepsis induces the release of several endotoxins, including proinflammatory and anti-inflammatory mediators. An uncontrolled inflammatory response has been implicated as an important pathogenic component of multiple systemic organ failure (1). It has been observed that interleukine-10 (IL-10), an anti-inflammatory cytokine, prevents lethality in experimental endotoxemia (2). The endogenous release of this cytokine could be produced in the early stage of sepsis and contribute to the control of proinflammatory mediators release such as TNF and IFN-γ, hence exerting a protective effect. It has been suggested that the liver itself could be a major source of IL-10 in Orthotopic Transplantation (3) The aim of the present study was to evaluate the particular role of the liver in IL-10 secretion in a porcine model of septic shock.

Materials and Methods: Pigs were injected with 1 to 50 μg of liposaccharide (LPS) via the portal vein (PV) ($n = 5$) or the pulmonary artery (PA) ($n = 6$), under general anesthesia Control animals ($n = 4$) were injected with saline in the same conditions Systemic and pulmonary blood pressure, cardiac output and oxygen extraction were continuously monitored during the experience. Serum levels of TNF and IL-10 were measured on blood samples from PV, suprahepatic vein, PA and femoral artery at different times after LPS injection. Cytokines levels were compared by student T-tests. $p < 0.05$ was accepted as significant

Results: In all experimental conditions, independently from the site of injection, the administration of LPS induced a profound state of septic shock indicated by systemic hypotension, tachycardia, decreased cardiac output and progressive acidosis This was correlated with TNF secretion (mean ± SE. 280 ± 281 U/ml at the peak, 60 min after LPS injection). In the 11 pigs injected with various amounts of LPS, in a dose-dependent manner, we detected a significant release of IL-10 (mean ± SE 450 ± 278 U/ml at the peak, 45 min after LPS injection) ($p < 0.05$ control vs LPS group). IL-10 was not measurable at any time in control pigs, injected with saline. There was no statistical differences in cytokines production between PV or PA LPS site of injection. Finally, we found no significant differences in IL-10 concentrations between portal vein, suprahepatic vein, pulmonary artery and femoral artery.

Conclusions: Septic shock, induced by the injection of LPS in pigs, is associated with a rapid and massive release of IL-10. The liver is not a predominant site of production of this cytokine in this situation

A.536 Prognostic value of immunomonitoring in patients with polytrauma and sepsis

K. Tschaikowsky, N Lehnert, A. Schiele, M Hedwig-Geissing, S. Kirchner-Holley, K Spegel. *Dept of Anesthesiology, Univ. Erlangen-Numberg, Krankenhausstr. 12, D-91054 Erlangen, Germany*

Background and Goal of Study: Thrombomodulin (TM) and procalcitonin (PCT) are released as a result of endothelial damage and systemic inflammation, respectively In addition, the expression of HLA-DR (%HLA-DR), and the ratio of T-helper to T-suppressor cells (CD4/CD8) on peripheral blood mononuclear cells (PBMC) are important markers of the corresponding cellular immune response. In this study, the prognostic value of TM, PCT, CD4/CD8 and %HLA-DR in patients after polytrauma and sepsis was investigated

Materials and Methods: 65 intensive care patients with polytrauma (P) and sepsis (S) were studied on day 1, 2, 3, 7, 10 and 14. TM and PCT were measured in plasma using ELISA (Diagnostica Stago) and ILMA (B.R.A H.M S.), respectively HLA-DR expression and CD4/CD8 were determined on PBMC by flow cytometry. We analyzed the relation between these soluble and cellular markers and the survival in group P and S

Results and Discussion: TM plasma concentrations (ng/ml) were significantly higher in septic patients than in patients after polytrauma (91 ± 45 vs. 40 ± 7 on d3). Polytrauma survivors and non-survivors can be discriminated by TM (60 vs. 31 ng/ml, mean d1–3) within the first three days. PCT plasma levels always decreased during the first days after polytrauma regardless of the outcome, but increased again in non-survivors. In group S, PCT was significantly increased and returned back to normal in survivors, but remained elevated above normal in non-survivors. Mean %HLA-DR positive blood monocytes was significantly reduced until day 10 both in group P and S compared with normal subjects. Whereas %HLA-DR was significantly lower on day 10 and 14 in septic patients who died, %HLA-DR could not discriminate survivors and non-survivors in polytrauma patients. In group S, non-survivors also showed diminished CD4/CD8 ratios that were consistently lower than in survivors, whereas in group P, CD4/CD8 was always increased and independent of the outcome.

Conclusion: TM may serve as a marker for injury severity in polytrauma patients discriminating survivors and non-survivors. The course of PCT seems to correlate with the outcome after polytrauma and sepsis. HLA-DR expression on monocytes and CD4/CD8 ratio are valuable prognostic markers in septic, but not in polytrauma patients.

A.537 Lactic acidosis during fulminant hepatic failure: determinants and infectious complications

J. Martínez, G Martínez-Pallí, J. Beltran, J. Ortells, P Taurà, C. Gomar. *Dept. of Anesthesiology, Hospital Clinic, Univ. of Barcelona, Spain*

Background and Goal of Study: In patients with fulminant hepatic failure (FHF), regional oxygen uptake becomes inadequate for tissue requenments The presence of lactic acidosis is a common feature which suggests tissue hypoxia. It contributes to bacterial translocation and sepsis leading to multiple organ failure which has a poor prognosis The aim of the study is to identify the hemodynamic and oxygenation parameters as well as the degree of encephalopathy and the incidence of infectious complications that may correlate with lactic acidosis in patients with FHF submitted to liver transplantation

Patients and Methods: Fifty-four patients with FHF (failure group (FG)) and 100 patients with end stage liver disease (control group CG) were studied Variables analyzed were age, mean arterial blood pressure, cardiac index, systemic vascular resistance, portal pressure gradient, arteriovenous oxygen difference, oxygen consumption, oxygen extraction ratio, respiratory quotient, plasma lactate levels, intrapulmonary shunt, degree of encephalopathy, intracranial pressure and infectious complications Statistical analysis was performed by means of *t* test and regression analysis. Data are reported as mean ± SE

Results: Both groups differed only in the degree of portal hypertension (FG: 12 5 ± 1 *vs* CG: 20 ± 0.7 mmHg, $p < 0\ 001$), and encephalopathy (FG. 3.8 ± 0 2 *vs* CG. 1 2 ± 0 05, $p < 0.001$) Moreover, 14/54 patients (51%) with FHF versus 13/100 (13%) presented any infectious process ($p = 0.04$) Among variables analyzed, only respiratory quotient was significantly related to the level of lactic acidosis.

Conclusions: 1) Both, hyperdynamic state and the degree of encephalopathy during FHF did not correlate with lactic acidosis. 2) There was no association between the degree of lactic acidosis and the incidence of infection 3) Finally, our data suggest an association between FHF and infectious complications.

A.538 Influence of n-acetylcysteine on leucocyte functions in critically ill patients

G Groth, A Heller, R. Breitkreutz, M. Quintel, T Koch *Dept of Anaesthesiology and Op Intensive Care Medicine, Faculty of Clinical Medicine Mannheim, University of Heidelberg, FRG*

Introduction: The antioxidant N-Acetylcysteine (NAC) has been shown to attenuate septic tissue injury [1, 2]. To evaluate whether NAC affects host defence mechanisms in critically ill patients, thus predisposing to increased risk of infection, the current study focuses on neutrophil phagocytotic and burst activity after treatment with NAC.

Patients and Methods: Until now, 26 patients diagnosed with sepsis/SIRS, pancreatitis or multiple trauma from the operative intensive care unit were included. All of them were mechanically ventilated when enrolled in the study 14 patients were treated with NAC in increasing doses (Table) for four days Blood samples were taken prior to NAC infusion (day 1), after increasing doses of NAC (day 3 and 5) and four days after the last treatment (day 8)

NAC (g/24 h)	6	12	18	18	–	–
day	1	2	3	4	5	8
PMN function	x	–	x	–	x	x

The same protocol was performed in 12 patients with comparable diseases which did not get NAC (controls). Neutrophil oxidative burst activity after stimulation with *Escherichia coli* and phorbol 12-myristat 13-actate (PMA) as well as PMN phagocytosis were determined in a flow cytometric assay. Differences between groups were tested by Student's t-test.

Results: Baseline values of PMN functions were comparable in both groups NAC treatment resulted in a significantly improved phagocytosis activity after increasing NAC up to 18g per day ($p < 0.05$, day 5) compared to control patients (mean values ± SEM: 398.2 ± 99.5 vs. 65 ± 8 4). In contrast to this, PMN burst activity did not differ significantly in NAC treated and control patients during the observation period.

Conclusion: These findings suggest that infusion of NAC in high doses did not impair granulocyte function in critically ill patients The enhanced phagocytotic activity point towards an improved granulocyte dependent host defence which may reduce the risk of infection

A.539 Plasma purification in treatment of patients with destructive forms of pancreatitis

V V Mamontov, V A Mokhov, V.N. Lucach, S I Vozlublenyi. ,

Goal: study of the efficiency of plasma purification during complex treatment of the patients with destructive forms of pancreatitis.

Stage of the intoxication was defined following clinical picture, presence of circulatory disorders, and three tests as well leucosytic index of intoxication, middle molecules mass in plasma and erythrocytes, circulating immune complexes Following it three groups of endotoxins were subtracted:

1st group 1.5 middle molecules fraction 0 25–0 5

2nd group 4–8 middle molecules fraction 0 5–1

3rd group 9–11 middle molecules fraction >1

Every patient underwent plasma purification by PF-05 apparatus, in constant regimen, involving venous extracorporal circle, using subclavian and femoral veins, volume of plasma exfusion was 70–80%

The efficiency of plasma purification was judged by such features as clinical and biochemical blood analysis.

Usage of plasma purification during complex treatment of the patients with destructive forms of pancreatitis gives the possibility to reach marked clinical effects and to improve the value of immunological status thus reducing the period of treatment of the patients in the intensive therapy department and to reduce mortality rate

---

A.540 Procalcitonin and systemic inflammatory response syndrome in postoperative intensive care patients

G Molter, R Kottke, S. Walcher, S Soltèsz, K Hegenauer[1], M Silomon
Clinic for Anaesthesiology and Intensive Care, [1]Department of General Surgery, Abdominal and Vascular Surgery, University Hospital, D-66421 Homburg/Saar, Germany

Background and Goal of the Study: Recent studies provide evidence that procalcitonin (PCT) is a reliable parameter for the evaluation of the activity and severity of infectious diseases in critically ill patients (1, 2) The present study was performed to investigate if the determination of serum procalcitonin concentrations can be useful in order to differentiate the state of systemic inflammatory response syndrome (SIRS) in postoperative intensive care patients.

Materials and Methods: 44 patients, 36 of whom met at least two of the criteria of SIRS [3], were studied With regard to the origin and course of the systemic inflammatory process the patients could be allocated to four groups: patients without apparent SIRS (I, control), patients suffering from SIRS without infection (II), without microbiologically proven infection but with successful anticipated antibiotic treatment (III), with microbiologically documented infection and confirmed or adjusted antibiotic treatment (IV). Mean values were calculated considering the daily determined serum PCT concentrations of day 1 to 5, and the maximal PCT levels of the intervals day 6 to 9 and day 10 until patients' discharge, respectively Within-group statistical analysis was performed using a Friedman-test followed by a Wilcoxon-Wilcox test, between-group statistics was calculated using a Kruskal-Wallis-test followed by a Durr-test

Results and Discussion: Serum PCT concentrations in group II remained almost within normal range and did not differ from the values obtained in the control group By contrast the PCT levels in group III and IV were markedly, and in part significantly, elevated compared to the control group These findings indicate that, in case of systemic inflammatory response, serum PCT concentrations are related to the presence or absence of microbial infection In addition, serum PCT concentrations in group III and IV decreased significantly under successful antibiotic treatment, suggesting that serum PCT concentrations reflect the state of severity of infection

Conclusions: Serum PCT concentration seems to be a suitable parameter to assess systemic inflammatory response in postoperative intensive care patients In addition, PCT may be helpful in surveying the efficacy of antibiotic treatment during the course of microbial infection

A.541 Criteria of severity and prognosis of severe asthma and status asthmaticus: a new approach to diagnosis

V.P Shano, A N. Nesterenko *Donetsk State Medical University Department of Anaesthesiology, Intensive Care and Emergency Medicine, Ukraine*

Background & Goal of Study: Effective and objective assessment of patient state's severity degree (PSSD) in Status Asthmaticus (SA) is a matter of topical interest in intensive care (IC). To raise efficacy of IC of SA through accelerating diagnosis and prognosis of SA outcome we used mathematical modelling.

Materials & Methods: Mathematical models of SA had been worked out on the base of statistical analysis computing data massif from 130 indices of 230 patients with severe asthma in SA Correlation analysis, the A. Ivakhnenkos' arguments group registration method had been used.

Results & Discussion: Mathematical models of SA have a form of the regression equations Here we present one version Y = −1.114 + 0 092X1 + 0.147X2 + 0 009X3 + 0 195X4 + 0.046X5 + 0 078X6 + 0 087X7+ 0.043X8 + 0.057X9 + 0.002X10 + 0.0095X11 + 0.214X18 + 0.134X27 + 0.372X37 + 0.001X44, where Y = index of PSSD, X1 = lucidity of consciousness; X2 = activity (position in bed); X3 = number of respiration per min., X4 = character of respiration; X5 = state of skin; X6 = cyanosis degree, X7 & X8 = lung auscultation data; X9 = sputum drainage; X10 = pulse rate; X14 = leucocytonic intoxication index; X16 = capillary blood PaCO2; X18 = lactic acid blood concentration; X27 = activity of blood AsAT, X37 = concentration of blood medial molecular peptides, X44 = concentration of circulating immune complexes. The meanings of $Y < 1.5$ conforms to the prolonged asthmatic attack; $1\ 5 < Y < 2.5$ conforms to I–II stages of SA, Y more than 2 5 conforms to III stage of SA The meanings of Y more than 3 5 with a tendency to rising were considered as unfavourable prognostication sign The trustworthiness of mathematical models' prognosis is 85%

Conclusion: Applying of mathematical modelling techniques led to reduction of the diagnosis time by a factor of 3; to ensuring the diagnosis reliability no less than 85%. It gives an efficient choice of optimum of IC and timely application of "active" methods· hemapheresis, hemoperfusion, hemo- or plasmoxenosplenoperfusion through pig spleen, ultraviolet irradiation of autoblood It allowed to reduce SA cupping time by a factor of 2.

A.542 Severe asthma and status asthmaticus: a role of xenosplenoperfusion in intensive care based on SIRS conception

V.P. Shano, A.N Nesterenko. *Donetsk State Medical University Department of Anaesthesiology, Intensive Care and Emergency Medicine, Ukraine*

Background & Goal of Study: It is not obvious, but the main mechanisms of pathogenesis of severe bronchial asthma (BA) and status asthmaticus (SA) is nonspecific systemic response (to allergens, infection, etc) with endogenous intoxication which intensified blockade of beta-2-adrenoreceptors. The goal of study was to prove on base of Systemic Inflammatory Response Syndrome (SIRS) conception that intensive care (IC) of severe BA and SA demands application of methods of active mediatoric management (MAMM) as obligatory component.

Materials & Methods: Analysis of treatment of 90 cases with severe BA (70 – in SA, stage I–II; 20 – in hypoxic & hypercapnic coma) had been done. Routine IC had been applied in 68 cases, IC with MAMM – in 22 ones. Protocol of treatment with active mediatoric management included fractional plasmapheresis with subsequent xenosplenoperfusion of obtained plasma through pig spleen, plasmatransfusion or hemoxenosplenoperfusion (original technique reserved: 29 12 87 SU 1556680; 24.07.97 UA 24223).

Results & Discussion: It had been considered that SA is a critical state with MOSF Simultaneous lesion of 4 organs had been revealed in 65 cases; 3 organs – in 78 ones. Respiratory insufficiency (artificial lung ventilation were carried out in 12 cases), incompetence of systemic and pulmonary circulation, endogenous intoxication due to severe metabolic, immunologic disorders and disbalance of cytokines confirmed SIRS presence It had been considered that complex IC with MAMM secured 30–50% reduction of SA cupping time and 40–50% reduction of treatment term in ICU, prolonged remission to 6–14 months. The lethality level had been decreased by a factor of 1.5–2

Conclusion: Complex IC of severe BA and SA with MOSF by application of active mediatoric management methods (plasma-or hemoxenosplenoperfusion) secured improvement of treatment results due to active detoxication, immunocorrection; restoration of patient's natural mechanisms of anti-infectious defence and systemic ability to detoxication

A.543 Tip-Hub story. Our experience

G Gucev, A. Damevski, V. Teneva, J. Hristova, M Micevski, M Petrovska, Z. Cekovska, T. Grdanoska, L. Damevska. *Clinic of Anesthesiology and Intensive Care, Medical Faculty-Skopje, Macedonia*

Background and Goal of Study: This prospective study was designed to analyze colonization of different parts of Central Venous Catheters and their relation to catheter-connected infections.

Materials and Methods: 84 PVC single lumen catheters for routine IV therapy and alimentary support of surgical ICU patients were included in the study After removal, 5 cm peace of the distal segment including the catheter tip was sectioned and sent to microbiology laboratory in sterile tube. The same was done with the catheter hub. Microbiological culture was done with Brun-Buison[1] modification of Cleri's[2] quantitative dilution technique. Findings were compared with the patient's clinical status x^2-test was employed for non-parametric data analysis.

Results and Discussion: Of 84 catheters, there were 27 positive tip cultures and 38 positive hub cultures Twenty one of 27 positive tip cultures were also positive hub cultures. This population of 21 was further analyzed by tipisation of the microorganisms. Tipisation revealed that in 15 cases catheter tip was colonized with the same flora as the hub, which suggests the hub as portal of entry ($x^2 = 3.85$). Join tip-hub colonization was connected with the highest incidence of catheter related sepsis and with the highest number of organisms recovered from quantitative culture ($5 \times 10^3 - 10^4$ CFU/ml).

Conclusion: The results of this study suggest that catheter hub colonization is an important step in pathogenesis of catheter related sepsis in our population of patients

A.544 Incidence of infection of arterial catheters in intensive care patients

P Kalfon[1], J. Prost[2], D. Kenmogné[1], F H Ansari[1], K. Chebbo[1], M Niault[1], F. Thomas[1], D. Francoual[2]. [1]*Réanimation polyvalente,* [2]*Laboratoire de biologie médicale, Hôpital des Diaconesses, Paris, France*

Background and Goal of the Study: First, the indications of invasive monitoring of arterial pressure with an indwelling catheter and its site of insertion in intensive care patients remain controversial Secondly, in comparison with studies dedicated to central venous catheters, there is little information about arterial catheter related sepsis (ART-CRS). That is the reason why we have initiated a prospective survey of ART-CRS in our polyvalent intensive care unit without modifying our existing practice

Methods: Thanks a catheter report form enclosed in each medical patient file, the following variables have been prospectively collected· **1) after the insertion of the catheter:** patient clinical data (underlying disease, SAPS II, ...), insertion site (radial, femoral, or humeral), number of punctures, operator's level of training, and insertion context (emergency or scheduled), **2) events during the use of the catheter:** antibiotic therapy, shock, **3) after the removal of the catheter:** reason for removal (suspicion of ART-CRS, mechanical problems [complete or partial obstruction leading to not reliable arterial pressure monitoring, inadvertent withdrawal], no more indicating, death), inflammation around of the exit-site just before the removal, and duration of catheterization.

A quantitative culture of the tip of the intravascular device according to *Brun-buisson et al* was performed. The diagnosis of catheter-related sepsis was based on clinical and microbiologic criteria[1].

Results: Between November 1996 and July 1997, 108 patients (age 67 ± 16 years), 141 catheters, and 1368 catheter-days were analysed. The following table shows the microbiologic results according to the insertion site.

	Total	(+)	$>10^3$	ILC	Duration (d)
Radial	108	31 29%	20 19%	4 4%	8 8 ± 7.3
Femoral	21	10 48%	7 33%	1 5%	9 1 ± 5 8
Humeral	12	7 58%	5 42%	2 17%	19 8 ± 9 7

Conclusion: A prospective survey of ART-CRS in intensive care patients permitted us to show prolonged catheterization durations (mainly for humeral catheters, probably because of difficult arterial access of the concerned patients) associated with high colonization and infection rates.

A.545 An intravenous catheter does not influence cytokine plasma concentrations

H. Keyer, K. Vissers, C. De Deyne, G. Vundelinckx, R. Heylen, R. De Jongh *Depts of Anesthesia, ZOL Sint-Jan, Genk, Belgium*

Background: Plasma levels of several substances are used as prognostic or biological markers and as a tool to study patho-physiological pathways. However, preanalytical variance can disturb the measurement accuracy. We studied the effect of the presence of an intravenous catheter in human volunteers on measurements of several biological substances in plasma.

Materials and Methods: In this cross-over randomized study, at 8 a m twelve volunteers received no catheter or a catheter in the antecubital vein after initial bloodsampling. At 3 p.m. another blood sample from the contralateral vein was withdrawn.

Results and Discussion: Good correlations and no significant differences between samples were found for gp 130, IL-6, IL-6R, LIFR, CRP, IL-1RA, sCD8, sCD25 Cortisol and CC 16 (Clara Cell Protein) levels were significantly lower at 3 p.m. both with and without catheter

Conclusion: for all measured cytokines, no influence of the presence of intravenous catheters was found. Circadian variations for cortisol and CC16 were observed.

A.546 Central venous catheterization in leukaemic patients with bleeding risk

A A Cogliati, G Conti, L Tritapepe, B Bottari, G. Rosa. *Department of Anesthesia and Intensive Care, University "La Sapienza" of Rome, Italy*

Background: We report our experience in positioning tunnelized central venous catheters in patients affected by hematological malignancies with bleeding disorders. Correction of bleeding disorders with Fresh Frozen Plasma and/or platelets infusion may decrease the incidence of related complications, but the administration of blood products is no risk-free and often it is impossible administer blood products prior to obtaining central venous access

Materials: We enrolled 68 consecutive patients (38 M/30 F) (median age. 34 yrs) with the following PLT counts PLT > 30.000 < 50 000/mL: 16 pts, PLT > 10.000 < 30 000/mL 32 pts, PLT < 10 000/mL 20 pts. In all patients PTT and PT was lower than 1 2 the normal values for the laboratory The catheters placed included Groshong 7F (60 pts) and 12 F dialysis catheter (8 pts) No patients received PLT infusion prior to the procedure.

Results: The subclavian vein was cannulated in 52 pts, the internal jugular vein in 16 pts. Fifty-four catheters (80%) were placed with a single pass of the needle, eight catheter placement (11%) required 3 or more (maximum 6) attempts. No serious complications were recorded (pnx, hemothorax, hemomediastinum, arterial puncture, etc) Five patients (7.3%) developed bleeding at the catheter exit site and seven (10 3%) had bleeding related to skin suture treated with local pressure and ice-bag

Conclusions: In our experience serious bleeding problems related to central venous cannulation is rare. Minor bleeding problems are easily controlled by local pressure and ice-bag The risk of bleeding complications seem to be independent to the approach used (1, 2) Correction of bleeding disorders by infusion of FFP and PLT is often done prior CVC insertion to minimize the bleeding risk but to our knowledge there are no report confirming this assumption. We conclude that CVC insertion can be safely performed by experienced physicians in patients with low thrombocyte count even without PLT infusion prior to the procedure

A.547 Significance of *Candida* species growth in respiratory samples from non-neutropenic patients in a surgical ICU

A. Alcón, N. Fábregas, F.X González, M A López-Boado, J P de la Bellacasa, J Balust, E. Zavala *Anaesthesia and Surgical Departments, Surgical Intensive Care Unit, Barcelona University, Hospital Clínic, Barcelona, Spain*

Background and Goal of Study: Critically ill surgical patients mechanically ventilated and treated with broad spectrum antibiotics are at risk of fungal colonization[1]. The threshold for infection and the indication for antifungal treatment are a dilemma

Materials and Methods: 656 patients admitted for more than 48 hours in a 8 bed Surgical Intensive Care Unit (SICU), from January 95 to October 97, were retrospectively analysed for the presence of *Candida* in respiratory samples taken from patients with respiratory tract infection.

Results and Discussion: 69 of the 656 patients (10.5%) had *Candida* growths in respiratory quantitative cultures Groups A = 11 patients with clinical pneumonia (VAP) whose *Candida* was the only isolated microorganism, B = 25 patients with VAP and polymicrobial culture; C = 8 patients with purulent tracheobronquitis (PTB) where only *Candida* was isolated and D = 25 patients suffering PTB with *Candida* and other isolated microorganisms 58% of the patients received antifungal therapy

Patients group	Apache II	Infection day	M v days	SICU length
VAP *Candida*	21 5 (7 7)	5 7 (2 4)	14 4 (7 4)	19 8 (14)
VAP Polymic	20 2 (5 7)	8 6 (7 3)	16 8 (13)	21 (13 4)
PTB *Candida*	22 5 (6 1)	5 5 (4 2)	11 7 (6 7)	17 (10)
PTB Polymic	18 4 (7 5)	6 7 (5 6)	14 5 (10)	17 (10 2)

M v = mechanical ventilation Data mean (SD)

We have not found statistically significant differences between the four studied groups. Only 1 patient developed invasive candidemia with a fatal outcome (1/69:1.4%) 2 patients (2/69·2.9%) had positive blood cultures. Crude mortality was 33.3% (23/69). None of the patients with PTB died due to infection.

Conclusion: *Candida* isolation in respiratory samples does not seem to imply a severe infection, hence suggesting a colonization

A.548 Community acquired pneumonia of rare origin

I Varga, B Hauser, C Diószeghy, E Benkovics, I Pénzes *Semmelweis Medical University, Budapest Dept of Anesthesia and Intensive Therapy, Hungary*

Community acquired pneumonia (CAP) is usually an uncomplicated case However, sometimes intensive care and even mechanical ventilation and circulatory support can be necessary if complicated with severe cardiorespiratory insufficiency (According to the literature in these cases the mortality of the mechanically ventilated patients can reach the 65–100%!)

Between 1995 and 1997 24 patients were admitted to our department with the diagnosis of CAP because of severe cardiorespiratory insufficiency Mean age was 29 years, 13 female and 11 male BAL, serology and the other conventional technics were used for establishing diagnosis The invective agents were· Mycoplasma in 10 cases, Legionella in 5 cases, Clamydia in 2 cases, virus in 2 cases and fungi in 3 cases We could not identify the invective agent in 2 cases

11 patients needed mechanical ventilation, the mean time on the ventilator was 26 days Mechanical ventilation could be avoided for 13 patients using the combination of the drug therapy and the aggressive physiotherapy (drug inhalation, NIPPV and Directed Forced Inspiratory Breathing) Severe clinical status was typical for all the 24 cases, but there was a correlation between the clinical presentation and the chest X-ray only in 6 cases (25%) When the chest X-ray morphology and clinical presentation suggested atypical agent, the usual empirical (combined) antibiotic therapy were supplemented with macrolid agent Targeted antibiotic therapy was started after the results of the resistance All the patients with septic shock (10 patients of all) were mechanically ventilated and 100% of them needed the combined inotropic therapy (dopamine + dobutamine + norepinephrine or/and epinephrin) and large dose volume substitution Among those who required artificial ventilation (11), 3 patients had died (27%).

We concluded, that the community acquired pneumonia caused by atypical agents often occur in healthy young adults with severe cardiorespiratory insufficiency The mycoplasma infection considered mild in nature so far, seems to be more dangerous. The complex intensive therapy and aggressive physiotherapy could be the lifesaving cornerstones of the treatment

A.549 Early postoperative percutaneous dilatational tracheotomy after cardiac surgery

M Bockelmann, N. Hubner, W Rees[1], U Christmann, H Warnecke *Dep Anesthesiology, [1]Dep Cardiac Surgery Schuchtermann Klinik, Bad Rothenfelde, Germany*

Methods: From 11/95 until 4/97 45 (1.6%) percutaneous dilatational tracheostomies were performed in a nonselected patient series of 2788 open cardiac surgery cases

Results: Tracheotomy was performed as early as postop, day (mean 6, range 2–14), when extubation was not foreseen within the next few days Duration of intubation was 13 days (mean) In five patients we observed 6 complications (13 3%), including, bleeding, misplacement of the tube, subcutaneous emphysema and superficial infection of the tracheostoma Mediastinitis and wound infection of the sternal wound did not occur in a single case Overall mortality was 26 7% No death occurred because of tracheotomy. Underlying disease was reason for the mortality Clinically evident tracheal stenosis and inadequate granulation of the stoma were nor seen after extubation.

Conclusions: Percutaneous dilatational tracheotomy is feasible with good results and minimal risk early after cardiac surgery with midline sternotomy. Increasing incidence of mediastinitis or infection of the sternal wound was not seen In our opinion, percutaneous dilatational tracheostomy is superior to standard surgical tracheotomy early after cardiac surgery

A.550 Early extubation after cardiac surgery: safe postoperative care management

M. Basora, G. Fita, C Gomar, I. Rovira, R. Cartaña, N Peix. *Departament of Anaesthesia, Hospital Clinic, University of Barcelona, Spain*

Background and Goal of Study: "Fast track" concept, which includes early extubation and early discharge from ICU [1,2], is a new trend to manage patients after cardiac surgery (CS). The goal of the study was to evaluate whether rapid emergence from anaesthesia along with earlier extubation would provide stable postoperative haemodynamics and good balance between oxygen delivery and oxygen consumption (DO_2/VO_2) after CS

Patients and Methods: We studied 20 cardiac patients, 59 (±11) years old undergoing elective CS. All patients were anesthetized with balanced technique with moderate doses of fentanyl. Anesthesia was maintained with isofluorane before bypass and with propofol infusion during and after bypass We measured mean blood pressure (MBP), mean pulmonary artery pressure (mPAP), continuous mixed venous saturation (cSvO2) and cardiac output. Cardiac index (CI), systemic and pulmonary vascular resistances (SVR, PVR) and quotient DO_2/VO_2 were calculated by standard formulae. All parameters were measured at post-anaesthesic induction (T1), after-bypass (T2), 20 minutes after initiation spontaneous ventilation (T3) and at extubation (T4).

Results: Results are shown in table 1. Time from the end of surgery to extubation was 330 ± 65 minutes

Table 1

	T1	T2	T3	T4
MBP (mmHg)	76 ± 11	78 ± 10	83 ± 14	79 ± 9
mPAP (mmHg)	20 ± 5	20 ± 5	20 ± 4	19 ± 4
CI (L/min/m^2)	1 8* ± 0 4	3 1* ± 0.9	3 3 ± 0 5	3.5 ± 0 5
PVR (mmHg)	167* ± 84	125* ± 47	138 ± 45	139 ± 63
SVR (mmHg)	1717* ± 480	1036* ± 230	1034 ± 293	1040 ± 346
SvO_2 (%)	76 ± 7	80 ± 6	76 ± 7	76 ± 7
DO_2/VO_2 (%)	0 25* ± 0 7	0 26* ± 0.7	0 22 ± 0.7	0 21 ± 0.6

Values expressed as Mean ± SD. *p < 0 05 T1 *vs* T2 (T-Test).

Conclusions: Fast track of patients undergoing CS does not result in haemodynamic instability nor in an imbalance between DO_2/VO_2

A.551 Lung injury score after cardiac surgery with CPB

J. Cruz, C. De La Cruz, A Castillo, F. Palma, A Mínguez, J Sarmiento. *Anaesthesiology Service (Surgical Intensive Care Unit), "Virgen de la Victoria" University Hospital, Campus Universitario Teatinos, Apartado 3091, 29010-Málaga, Spain*

Background & Goal of Study: It is well known since long time ago, that cardiopulmonary bypass (CPB) alters pulmonary function, inducing a spectrum of lung pathology similar to that of acute lung injury[1] The aim of this study is to report prospectively the evolution of the Lung Injury Score (LIS)[2], as a mean to evaluate the degree of this acute lung injury after cardiac surgery with CPB.

Material & Methods: Patients admitted to the surgical intensive care unit (SICU) after scheduled cardiac surgery were included. Obstructive chronical pulmonary disease was an exclusion criteria The score was obtained at admission in the SICU, at intervals of six hours the first 24 hours and at the 2nd and 3rd day. Type of surgery, length of CPB and cross-clamping and length of mechanical ventilation were recorded. Data are presented as mean values; for LIS scores, 95% confidence interval is given between brackets Statistical analysis was made with the Student's t and ANOVA tests, considering $p \leq 0.05$ as significance level.

Results & Discussion: Fifty patients were studied, age 60.2 years, 31 men (62%) and 19 women (38%). CABG was performed in 29 (58%). Time of CPB and cross-clamping were 111.6 and 72 9 minutes respectively. Extubation could be performed before 24 hours (10 5 hours) in 88% and in the remaining 12% after (49.1 hours) Scores in LIS were: admission, 0 2 (0.03–0.37); 6 hours, 0.15 (0 03–0.33), 12 hours, 0.4 (0 2–0.6); 18 hours, 0.58 (0.38–0.77); 24 hours, 0 46 (0.26–0 66); 48 hours, 0 45 (0.25–0 66) and 72 hours, 0.47 (0.23–0.7). This increase in LIS score from 18 hours and on, was significant ($p < 0\ 0009$). There were not differences between CABG and valve surgery ($p < 0.11$). Patients with CPB lengthening more than 90 minutes did not have higher scores ($p < 0.1$). Patients with mechanical ventilation ≥ 24 hours had a maximal score of 1 14, and patients with <24 hours a score of 0.74 ($p < 0.025$). General anaesthesia, midesternal incision, extravascular lung water, CPB and other factors are responsible for increase in LIS after cardiac surgery[3]. An elevated work of breathing after extubation is reflexed by a new increase in LIS from 18 hours postadmission.

Conclusion: Evolution of LIS after cardiac surgery reflexes in a right way postoperative pulmonary changes.

A.552 Sedation after coronary artery bypass surgery

P. Broere, H. Cromheecke, A. de Boer, J Leusink. *St. Antonius Hospital, Nieuwegein, The Netherlands*

Background: In the first hours after CABG-surgery the patient will often present with haemodynamic instability. This possibly increases the risk for postoperative myocardial ischaemia. Adequate postoperative sedation is therefore indicated until the patient has been stabilised (1) This study compares the quality of sedation and the haemodynamic effects of propofol, midazolam and diazepam in these first hours after CABG-surgery

Methods: 45 patients, scheduled for primary CABG, were included. Preoperative anaesthetic regimens were standardized. Postoperatively patients were allocated randomly to three groups (N = 15). Two groups received double-blind either propofol or midazolam by continuous infusion The third group was given diazepam 5 mg boluses on a p r n. basis (max 20 mg in the first four hours) All patients were sedated for at least the first four hours postoperatively, titrating infusion-rates to maintain patients at sedation-level 3–4 on the Ramsay sedation scale

Results: Adequate sedation was achieved during 78 6% of the period for propofol, during 71 4% for midazolam and 66.7% for diazepam. After stopping sedation spontaneous ventilation resumed fastest in the midazolam group (after resp 283 minutes for midazolam, 353 minutes for propofol and 485 minutes for diazepam). These differences are not statistically significant During the first four postoperative hours diazepam had for 55% of this period a pulse-rate >90 beats/min. This is significantly longer as compared with both midazolam (34%) ($p = 0\ 01$) and to propofol (40%) ($p = 0.05$). Propofol exceeded for the shortest time-interval the maximal systolic target value of 120 mmHg (12.6%), although this was not significant compared with midazolam (17.6%) and with diazepam (23 1%). Patients given diazepam had a significantly greater amount of postoperative blood-loss (567 ml), as compared with patients given propofol (445 ml) ($p = 0.05$), and patients given midazolam (409 ml) ($p = 0\ 03$).

Discussion: Propofol and midazolam provided a comparable quality of sedation. After stopping sedation patients given midazolam resumed spontaneous ventilation quickest. As compared with diazepam both propofol and midazolam provided an haemodynamically more stable sedation, with a significant reduction in heart-rate and less postoperative blood-loss.

A.553 B-mode echography in the diagnosis of radiological maxillary sinusitis

A C Dzierzeck, S. Robert, J.C. Ferné[1], L. Paladini, J.M Pechier, J Fusciardi. *Department of Anaesthesia and Surgical Intensive Care;*
[1]Department of Radiology University Hospital of Poitiers, France

Goal of the Study: Nosocomial maxillary sinusitis is a complication of nasotracheal intubation (1) Doing a CT scan (CT), which is the gold standard for the diagnosis of RMS, can be difficult in instable ICU patients. The B-mode E has good specificity and sensibility (2), but ICU patients were not evaluated. The aim of this prospective study was to assess the B-mode E in the diagnosis of nosocomial RMS

Materials and Methods: 18 consecutive ICU patients, oro-trachealy intubated and recuiring a CT were studied. In everyone were performed CT paranasal sinuses slices and a E E was realised with a 3.5 Mhz probe, in the canine fossa, using longitudinal and transversal sections, in dorsal decubitus and half seated positions. E was performed by the 2 same intensivists who were not aware of the CT result When the posterior sinus wall was seen, E was defined as positive

Results: 36 sinus were studied *CT* showed 15 empty sinus cavities, 11 mucosal thickening (2 of them with an virtual sinus cavity), 6 air fluid levels and 4 complete opacities *E:* the feasibility was 100%, 26 were negatives and 10 positives.

CT scan	RMS–	RMS+
Positive echography	2	8
Negative echography	24	2

For E: sensibility was 80%, specificity 92%, positive predictive value 80% and negative predictive value 92%.

Discussion: Our results shown that performance of E observed in non ICU patients is verified in ICU patients (2). We had 2 false positive because this technique can't differentiate a total filling of the sinus cavity by a mucosal thickening or a liquid (mucosal or purulent) We did not compare these morphologic exams to the bacteriological analysis of the sinus aspirate, because few of our patients had clinical criteria for an infectious sinusitis. More inclusions are needed to study this point.

Conclusion: Bedside B-mode E in the diagnosis of RMS is easy and reproducible. To our opinion it could be an alternative to CT in the diagnosis of nosocomial RMS in unstable ICU patients

A.554 Acute renal failure in the ICU

H. Flaatten. *Dep of Anaesthesiology and Intensive Care, University Hospital of Bergen, Norway*

Background: This study was conducted in order to compare two different groups of patients with ARF in the ICU. The association with multiorgan failure (MOF) and the six months survival rate were also investigated

Materials and Methods: Since 1994 our ICU patients with ARF have been assigned to one of two groups *Postoperative ARF* (ARF occurring in a patient within 72 hours after surgery) and *non-operative ARF* (as occurring after major infections) Only patients in need of renal replacement therapy (RRT) were included. Using a clinical database (REGINA®), age, sex, length of stay, diagnosis and therapeutic interventions (including ventilator days and days with RRT) were prospectively registered. Since January 1996 all patients have been scored (after 24 h) using the SAPS II severity scoring system (1) and with a daily simplified therapeutic intervention score, NEMS (2) Follow up of deaths occurring after discharge was possible by searching the Norwegain health registry

Results: 146 patients have been included in the 46 months period from January 1994 until October 1997, 72 with postoperative ARF and 76 with non-operative ARF Differences (mean ± SEM or %) between the two groups are given in table 1.

Table 1

	Postoperative ARF (n = 72)	Non-operative ARF (n = 74)
Age (years)	71.9 ± 1 3	55 9 ± 2 3
ICU stay (days)	9 5 ± 1.0	13 7 ± 1 7
Ventilator days	8.0 ± 1.0	12 0 ± 1 7
RRT (days)	6 2 ± 0.9	10 3 ± 1 6
SAPS II	56 1 ± 2 1	65.1 ± 3 4
NEMS/ICU stay	329 ± 34	480 ± 65
MOF (%)	76.3%	88%
ICU survival	54 1%	49 3%
6 months surv	37 5%	37 3%

The SAPS II estimated hospital survival was 42% for the postoperative ARF group and 23% for non-operative ARF

Conclusions: Most patients with ARF also have MOF in the ICU, and this combination still have a high mortality. Patients with postoperative ARF patients are older but less sick compared to non-operative ARF No significant differences in six months survival rate could be found, indicating that age more than severity of disease determines long term survival.

A.555 Pancreatitis-associated protein reveals protective effects on pulmonary vasculature

A Heller, V. Lück, A Samakas, F. Fiedler, T Koch. *Dept. of Anaesthesiology and Op Intensive Care Medicine, Faculty of Clinical Medicine Mannheim, University of Heidelberg, FRG*

Introduction: Severe pancreatitis is often complicated by acute lung failure. It has been demonstrated that a specific pancreatic secretory protein is elevated during pancreatitis in the blood (200–1400 ng/ml) [1]. The expression of PP correlates with the severity of pancreatitis but increased PP levels prevented lethal pancreatitis in rats. Aim of this study was to investigate potential protective effects of PP on pulmonary vasculature after inflammatory PMN activation with fMLP.

Material and Methods: The experiments were performed in isolated and ventilated rabbit lungs which were perfused with 200 ml of Krebs-Henseleit buffer with a constant flow of 150 ml/min in a recirculating system It was tested whether pretreatment with PP (260 ng/ml; n = 9 or 500 ng/ml; n = 2) prior to fMLP injection influences pulmonary artery pressure (pap) and edema formation as assessed by lung weight gain

Results: Baseline values of pap were 8.0 ± 1.7 mmHg fMLP application resulted in an acute significant ($p < 0\ 01$) increase of pap (26 1 ± 6 1 mmHg). After pre-treatment with PP the pressure response due to the fMLP challenge was dose dependently reduced to 14.6 ± 2.3 mmHg (PP 260 ng/ml; $p < 0.05$) and 8 8 ± 3.9 mmHg (PP 500 ng/ml), respectively. Lung edema formation occurred in the fMLP group but was absent after PP-treatment in either concentration.

Conclusion: PP did prevent fMLP induced vasoconstriction and edema formation in the lung These findings point towards a protective effect of PP on PMN mediated lung injury. Elevated levels of pap during pancreatitis could reflect a compensatory organ protective mechanism Further studies are required to elucidate the pathophysiological impact of PP.

A.556 Partial liquid ventilation, positive end-expiratory pressure and nitric oxide inhalation in an animal model of acute lung injury

M Max, R. Kuhlen, S.M. Reyle-Hahn, J Baumert, R Dembinski, R. Rossaint. *Klinik für Anaesthesie, RWTH Aachen, Pauwelsstraße 30, 52074 Aachen, Germany*

Background: Partial liquid ventilation with perfluoro-carbons and PEEP lead to a recruitment of collapsed alveoli, thereby improving arterial oxygenation in acute lung injury (ALI). Inhalation of NO can further increase PaO_2, depending on the number of well-ventilated lung segments We compared the effects of PEEP and partial liquid ventilation, each with and without inhaled NO on gas exchange and hemodynamics in experimental ALI.

Methods: ALI was induced in seven pigs (25 ± 5 kg BW) using a saline lung lavage model Gas exchange and hemodynamic parameters were determined at two levels of PEEP (5 cmH_2O and 15 cmH_2O) before and after initiation of partial liquid ventilation (10 ml/kg BW perfluoro-carbon, FC3280®, 3M), each with and without the combined inhalation of 10 ppm NO. Data are presented as mean ± SD, statistical analysis was performed using ANOVA for repeated measurements followed by Bonferoni's multiple comparison test.

Results: Significant changes in cardiac output (CO) and PaO_2 were observed only at a PEEP level of 15 cmH_2O during mechanical ventilation as well as partial liquid ventilation. Inhalation of NO had a distinct, although not significant effect on PaO_2 without affecting CO The venous admixture (Q_{VA}/Q_T) improved due to inhaled NO, PEEP and partial liquid ventilation, while all studied hemodynamic parameters remained substantially unchanged when compared to ALI.

	PEEP [cmH_2O]	NO [ppm]	PaO_2 [mmHg]	CO [l/min]	(Q_{VA}/Q_T) [%]

V	15		291 ± 148*	3 7 ± 1 4*	21 ± 6*
	15	10	317 ± 147*	3 7 ± 1 8*	19 ± 5*

* $P < 0\ 05$ when compared to ALI

Conclusions: We conclude that the application of high levels of PEEP can be as effective as partial liquid ventilation with small doses of perfluorocarbon in improving PaO_2 and Q_{VA}/Q_T in a saline lung lavage model of ALI.

A.557 Predicting the patient's response to changes in mechanical ventilation: a comparison of physicians and a physiological simulator

N M. Bedforth, J G. Hardman, R P. Mahajan, A.R. Aitkenhead *University Department of Anaesthesia, University Hospital, Nottingham, NG7 2UH, UK*

Background and Goal of Study: Changes to ventilator settings are part of the normal management of mechanically ventilated patients on the intensive care unit (ICU). Physiological simulations have provided useful predictions of blood gas responses to interventions in mechanical ventilation [1]. We have developed a physiological simulator (The Nottingham Physiology Simulator: NPS). In order to have value as a clinical predictive tool, the simulator needs to be consistently more accurate than a physician. This study aimed to compare the ability of the NPS and ICU physicians to predict changes in arterial oxygen tension (*PaO_2*) after alterations were made to ventilator settings.

Materials and Methods: The NPS is a computer simulation of original multi-compartmental physiological models We collected 25 data sets from mechanically ventilated ICU patients before and ten minutes after changes had been made in ventilator settings (inspired oxygen fraction and minute volume) Each data set included arterial blood gas analysis, ventilator settings, haemoglobin concentration and temperature. The simulator and 6 ICU consultants were provided with the patients' pre-intervention data sets and details of changes in ventilator settings Each provided predictions for changes in *PaO_2*

Results and Discussion: Mean magnitude of change of FiO_2 was 0 15 (SD 0.06) and mean magnitude of change of minute volume was 700 (SD 1000) ml. Mean absolute change in PaO_2 was 5.95 (SD 3.23) kPa. Values in the table are given for the mean absolute size of error (bias) for the NPS and the 6 ICU consultants (1–6). A negative value thus represents an underestimation of the size of change in PaO_2 and vice versa The scatter of error sizes is described by the 95% confidence interval of the bias (CI_{95}). The NPS was more accurate and consistent than any of the six ICU consultants.

	NPS	1	2	3	4	5	6
Bias (kPa)	0.3	−3 2	−1.4	−2 8	−1.3	−3 6	−0 7
CI_{95} (kPa)	± 0.4	± 1.3	± 0 7	± 1 2	± 1 2	± 1 2	± 1 1

Conclusion: The simulator may prove to be a useful predictive tool in the management of ventilation on ICU

A.558 Consecutive sucralfate 0.7% aspiration into the lungs of rats: acute, subacute and chronic histological effects

H Canatay *Marmara University Faculty of Dentistry, Istanbul, Turkey*

Background & Goal of Study: Aspiration of gastric contents continues to be a concern of physicians involved in the care of critically ill patients. Previous researches have focused on the single aspiration of sucralfate in various concentrations and amounts (1, 2) But recurrent events of aspiration are more likely to happen in critically ill patients. The aim of this study was to evaluate acute, subacute and chronic histologic effects of recurrent % 0.7 sucralfate aspiration.

Materials & Methods: 24 Sprague-Dawley rats were randomly divided into two groups (Control group, (n: 6); study group (n: 18)). Simulated aspiration of 0.5 ml/kg either % 0.7 sucralfate or % 0.9 normal saline with 24 hours interval for 3 days were induced by direct tracheal instillation. Control and study groups were divided into A, B, and C subgroups. Animals in subgroubs A (Acute), B (subacute), C (Chronic) were killed respectively, 4 hours, 7 days, 21 days after the last aspiration to evaluate acute, subacute and chronic histological changes of airways.

Results: In the control animals, there were no significant difference ($P > 0.5$) in histologic findings in the acute subacute, and chronic periods. In the acute period of the study subgroup (4th hour), there were significantly different ($P < 0.5$) acute inflammatory reactions, atelectasis and edema at any time interval studied. In the subacute period of the study subgroup (7th day), there were significant ($P < 0.5$) chronic inflammatory reactions. These chronic inflammatory reactions were not significant in the 21st day among other subgroups.

Conclusion: Recurrent 0 7% low volume sucralfete aspiration produced significant inflammatory airway lesions in the acute period These abnormalities resolved without any chronic progression in the chronic period

A.559 Bronchoalveolar lavage with a diluted surfactant suspension before surfactant instillation improves the effectiveness of surfactant therapy in experimental acute respiratory distress syndrome

D. Gommers, E P. Eijking, A. van 't Veen, B Lachmann. *Dept. of Anesthesiology, Erasmus University Rotterdam, The Netherlands*

Goal of the Study: To assess whether bronchoalveolar lavage (BAL) with a diluted surfactant suspension prior to surfactant instillation prevents the only transient improvement in lung function as reported after surfactant instillation in severe acute respiratory distress syndrome (ARDS) [1]

Materials and Methods: Adult male Spraque-Dawley rats underwent repetitive whole lung saline lavage to induce acute lung injury.[2] Then, animals were randomly divided into six study groups: the first group received surfactant (150 mg/kg) within 10 min after the last lavage (early treatment), whereas in the other five groups mechanical ventilation was continued for 3 h before treatment (late treatment). Treatment consisted of: surfactant instillation (150 mg/kg); BAL with saline; BAL with a diluted surfactant suspension (2.5 mg/ml); BAL with saline, immediately followed by surfactant instillation (150 mg/kg); and BAL with a diluted surfactant suspension (2.5 mg/kg), immediately followed by surfactant instillation (150 mg/kg)

Results: Blood gases were measured for 6 h and then BAL was performed to measure protein concentration and surface tension properties Mean PaO_2 values increased immediately after surfactant instillation to pre-lavage values and remained stable only in the group that received surfactant immediately after lavage procedure and the group that underwent BAL with a diluted surfactant suspension prior to surfactant instillation

Conclusion: BAL with a diluted surfactant suspension prior to surfactant instillation at a later time point in lung injury resulted in a stable improvement of lung function. This improvement is comparable with the results seen after surfactant instillation immediately after lung lavage

A.560 Mechanical ventilation during closed system suctioning

M. Kirmse, C. Schmidt, H Mang *Clinic for Anaesthesiology University of Erlangen-Nuremberg, 91054 Erlangen, Germany*

Background & Goal of Study: Closed systems for tracheo-bronchial suctioning (CSS) are superior to open suctioning with regard to gas exchange and hemodynamics. However, the interaction of modern ventilators and CSS regarding preservation of PEEP and ventilation has not been described yet [1]

Material & Methods: We did a bench test evaluation of a 14F closed tracheal suction system and four different ICU ventilators Our lung model had an FRC of 900 ml, compliance was 29 ml/mbar and resistance was 12 mbar/l/s. Suction was 0.7 Bar against occlusion. Against atmosphere, flow through the system was 341/min. We measured pressure and flow at the Y-piece and in the artificial trachea with two Bicore CP 100 pulmonary mechanics monitors. We investigated tube sizes 7.0, 7 5, 8 0 and 8 5 mm I.D. and volume (VCV) and pressure constant ventilation (PCV) with PEEP = 12 mbar, I·E ratio = 1:1, f = 15/min, minute ventilation (MV) = 101/min or inspiratory pressure = 21 mbar above PEEP Measurements were taken for 15s before (baseline) and after introducing the suction catheter and during continuous suctioning.

Results & Discussion: 1. Introducing the suction catheter during PCV led to a reduction in MV which depended on tube size. Auto-PEEP developed with 7.0 and 7.5 mm tubes only and was higher with VCV than with PCV. 2 With PCV and tubes of 8.0 and 8.5 mm PEEP was maintained during suctioning. 3. With PCV, FRC was maintained whereas it was fully (7.0 and 7.5 mm) or partly (8.0 and 8 5 mm) evacuated with VCV. 4. With PCV and 7.0 and 7.5 mm tubes, there was no ventilation during suctioning whereas with 8.0 and 8.5 mm tubes we found a MV of 7.3 and 9.51/min, respectively. With VCV, there was no relevant ventilation. A sensitive trigger was essential for PEEP upkeep and ventilation during CSS.

Conclusions: With a 14F catheter, only pressure constant ventilation with an active inspiratory trigger and a 8.0 mm I.D. or bigger tracheal tube maintained FRC and ventilation during suctioning.

A.561 Induction of chromosome aberrations in peripheral blood lymphocytes after short-term inhalation of nitric oxide

O. Luhr, C. Frostell, R. Heywood, S. Riley, P-A Lonnqvist. *Division of Anaesthesia and Intensive care, Karolinska Institute at Danderyd Hospital, Stockholm, Sweden*

Background and Goal of Study: Inhalation of nitric oxide (INO) leads to vasodilation of pulmonary vasculature in ventilated regions of the lung resulting in selective pulmonary vasodilation. The clinical use of INO, although not formally approved as a drug, is widespread. NO may rapidly form nitrogen dioxide (NO_2) in an oxygen containing gas mixture. NO_2 has been shown to induce chromosome aberrations and mutations in both animal and bacterial test systems. A widely used end-point to evaluate the potential of a chemical agent to induce somatic mutations in exposed individuals, is measurement of chromosome aberration frequencies in cultured human peripheral blood lymphocytes. We investigated whether a 2-hour exposure to NO would increase frequencies of cells with chromosome aberrations in peripheral blood lymphocytes of human volunteers We also studied the effect on liver, kidney and haematological routine laboratory measurements.

Materials and Methods: Ten volunteers were exposed to inhaled NO 40 parts per million (ppm) for 2 hours. Pre- and post-exposure blood samples were analysed for chromosome aberrations using a chi-square probability distribution.

Results and Discussion: The proportion of cells from the pre-exposure samples from the volunteers all fell within the normal range with respect to structural aberrations (without and with gaps) No statistically significant differences ($p \leq 0$ 05) were observed between frequencies of aberrations in cultures established from the pre- and post-exposure samples No clinically significant alterations in kidney, liver or haematologic laboratory parameters after the exposure could be detected

Conclusion: This study demonstrates, in healthy adult volunteers, that a 2-hour exposure to inhaled nitric oxide 40 ppm in 30% oxygen, results in no detectable increase of chromosome aberrations in cultures established from peripheral blood lymphocytes in samples isolated prior to inhalation and 60 minutes after discontinuation of inhalation

A.562 Resonant frequency in ARDS using superimposed high-frequency jet-ventilation

A Kepka, G. Ihra, C Schabernig, P Kraincuk, A. Aloy. *Dept. of Anaesthesiology and Intensive Care Medicine University of Vienna, A-1090, Austria*

Background and Goal of the Study: The mechanisms how high-frequency (HF) jet-ventilation techniques work have not been resolved completely (1, 2). Animal models lead to the assumption that HF ventilation with respiratory rates close to the resonant frequency (RF) could improve oxygenation The RF is achieved by the HF-part of the ventilation and may improve oxygenation (3).

Materials and Methods: 1 patient with ARDS was studied using SHFJV characterized by the simultaneous application of a low-frequency and a high-frequency jet-stream The RF was found by measuring airway pressure amplitudes inside the endotracheal tube during a stepwise increase of the HF pulsation's. The pressure changes were recorded and wave forms analyzed The area with the largest amplitudes represented the respirator setting were HF-rate was close to RF RF was determined at normal pulmonary function and during increasing pulmonary insufficiency due to pneumonia The measurements were continued until the patient regained normal lung function

Results: The results are presented in the following table.

Day	Murray Sc	Pa02/FiO2	RF
1	1	209 5	730
5	2 3	140 8	630
7	3 3	73 6	500
10	3	250	600
11	2	341 3	730

Discussion: The invasiveness of mechanical ventilation correlated with increasing pulmonary insufficiency and determined RF shift to a lower frequency. These changes correlated with the Murray Score However, improvement of pulmonary function was accompanied by a shift of RF back to the original higher frequency.

Conclusion: This presented case demonstrates that RF does change when lung function deteriorates and may be markedly lower than during normal lung function As RF may change daily it has to be determined regularly to set HF-rate for optimization of gas exchange.

A.563 Superimposed high-frequency jet-ventilation combined with inhalation of nitric oxide in ARDS

A. Kepka, C Schabernig, G. Ihra, P Kraincuk, A Aloy *Dept Anaesthesiology and Intensive Care Medicine, University of Vienna, A-1090, Austria*

Introduction: Inhaled nitric oxide (NO) reduces pulmonary hypertension in severe ARDS and improves arterial oxygenation by redistributing blood flow to areas with a nomal ventilation/perfusion ratio (1) As high peak inspiratory pressure (PIP) may contribute to pulmonary damage ventilatory strategies like high-frequency (HF) ventilation search to minimize PIP This study was designed to evaluate the combined benefits of superimposed high-frequency jet-ventilation (SHFJV), a new HF jet-ventilation technique, with addition of inhalational NO

Methods: 10 patients with severe ARDS were evaluated. All patients where ventilated with a conventional respirator (Evita, Drager Germany). The indication for SHFJV was a Horrowitz Index below 100. An electronic prototype jet-ventilator (Alexander 1, Reiner, Austria) used for SHFJV provided simultaneous low- (14–20/min) and high-frequency (400–600/min) jet-streams, which were applied with a special jet-adapter For application of NO we used the Pulmonox mini (Messer Griesheim, Austria) including a specially developed computer software for precise addition of NO (10 ppm) to the HF jet-stream during inspiration (2). After 3 hours of jet-ventilation we additionally applied NO

Results: PaO_2/FiO_2 and Horowitz index increased during SHFJV and NO application, while PIP could be reduced maintaining the same levels of CO_2 (Table 1)

Table 1

	CPPV	SHFJV	SHFJV and NO
Oxygenation	19 7	16 8	13 9
Horrowitz	96	118	149
PIP (cm H_2O)	34	30	30

Conclusion: The beneficial effect of SHFJV on oxygenation can be combined with the selective effects of inhaled NO. Thereby, impaired pulmonary function can be further improved.

A.564 A new high-frequency jet-ventilation technique in a patient with ARDS

G. Ihra, C Schabernig, A. Kepka, P. Kraincuk, A. Aloy *Dept of Anaesthesiology and Intensive Care Medicine, University of Vienna, Austria*

Introduction: High-frequency (HF) jet-ventilation has been introduced by Klain et al and is utilized as alternative ventilatory modality for patients during laryngeal surgery or pulmonary insufficiency (1) Here we report about a patient with ARDS, where superimposed HF jet-ventilation (SHFJV), an advanced jet-ventilation technique, applied with a special jet-adapter, considerably improved oxygenation

Case: A 44 yr old man was admitted to a surgical intensive care unit because of severe sepsis due to intrabadominal infection Subsequently, adult respiratory distress syndrome developed (Murray score 3 5) and the patient was ventilated with FiO_2 0 7, I E = 1, PEEP = 15 cm H_2O, Ppeak = 32 cm H_2O when HF ventilation was initiated on the 6th day after admission to the ICU. A new jet-ventilation technique, superimposed HF jet-ventilation (SHFJV), was utilized SHFJV was characterized by the simultaneous application of a high-frequent and a low-frequent jet stream via two separate small-bore cannulas using a special jet-adapter, which was connected to the conventional endotracheal tube. Settings of the electronic prototype jet-ventilator (Alexander I, Reiner, Austria) and airway pressures were comparable with the preceding conventional ventilation except the high-frequency rate set to 500/min and the low-frequency respiratory rate set to 20/min SHFJV resulted in a considerable increase in pO2 levels from 114 to 334 mmHg (+192%) within one hour and high FiO_2 was substantially reduced. SHFJV also enabled adequate CO_2-elimination with pCO_2 levels decreasing from 38.5 to 30 8 mmHg. Heart rate (98 *vs* 101 b/min), arterial blood pressures (MAP 69 *vs* 72 mmHg) and cardiac output (8 39 *vs* 8.52 L/min) did not change Likewise, mean pulmonary artery pressure (33 *vs* 35 mmHg) and pulmonary capillary wedge pressure (17 *vs* 17 mmHg) remained unaffected. No ventilator associated complication was observed and SHFJV was continued. However, the patient died due to multiple organ failure on the 8th day

Conclusion: This case of ARDS shows, that SHFJV by combining high-frequency and low-frequency jet-ventilation appears to be an effective ventilatory support to improve impaired oxygenation Furthermore, SHFJV can be performed over several days because it facilitates normal CO_2 elimination

A.565 A new method of quantification of ventilated areas: preliminary data

P. Kraincuk, F. Vorbeck, A. Kepka, C. Schabernig, G Ihra, A Aloy.
Department of Anesthesiology and General Intensive Care, University of Vienna, Austria

Background & Goal of Study: This pilot study reports of the unprecedented possibility to objectify the recruitment of atelectatic areas with a mobile CT, in patients who are served superimposed high-frequency jet-ventilation (SHFJV).[1]

Material & Methods: After institutional approval four patients, three male and one female with a mean age of 52 years (ranging 21 to 83 years) received SHFJV for four hours by a prototype of a new electronic jet ventilator named ALEXANDER 1. Blood gas analyses were taken every half hour during the whole study period A thorax CT (mobile CT, Philips Tomoscan M, Netherlands), was taken of every patient before and after the period of ventilation with the possibility of 3D reconstruction The ventilated areas of each thoracic CT-picture were digitally remastered and volumetricly measured down to one ccm by a serial scan of the lungs We were always using the same parameters a matrix of 512 to 512, a zoom factor of 1.4, slicethickness 1.0 cm, pitch 1.0 cm, a trash hold of –400 to –1000 HE. Additionally, a high resolution CT (HR-CT) was performed of every patient's lungs (slicethickness 0.2 cm, pitch 1.5 cm, same trash hold and same matrix as in the serial scan) before and after jet-ventilation, in order to detect any alteration of the parenchyma or changing of the diameters of the bronchi. Data export was performed via DICOM III on a Philips Easy Vision 2.1.2 Sun Sparc Station 5

Results & Discussion: The situation of every lung improved The average amount of the improvement of the ventilated areas were 329 ccm, which represented an average increase of 11.7% In analogy of these values, we saw that the Pa02 measurements of the arterial blood gas analyses were improving too. The average increase of the Pa02 value amounted to 40.4% within the period of SHFJV, meaning that the improvement of the ventilation (recruitment of the atelectatic areas) leads to a better oxygenation Regarding the HR-CT, we saw no dilatation of the bronchi, but a decrease of the atelctatic areas within a reduction of the ground glas obesity

	Pat 01	Pat 02	Pat 03	Pat 04
Ventilated area				
before (ccm)	4398	2233	2524	3265
after (ccm)	4734	2764	2613	3525
difference (ccm)	336	531	189	260
percent (%)	7.6	23.7	7.48	7.91
Pa02				
before (ccm)	90.6	102.1	101.2	120.6
after (ccm)	140.7	143.2	146.4	152.8
difference (ccm)	50.1	41.1	45.3	32.2
percent (%)	50.1	40.2	44.7	26.6

Conclusion: The improvement of the ventilation and oxygenation can be umpirely objectified with this method. This possibility visualizes the advantages of superimposed high-frequency jet-ventilation.

RESUSCITATION AND EMERGENCY MEDICINE

A.566 Circulatory effects of hypertonic saline/dextran during uncontrolled intra-abdominal bleeding

H. Hjelmqvist[1,2], A. Suneson[2], R.G. Hahn[2], L. Riddéz[2]. [1] *Dept. of Anaesthesiology and Intensive Care, Huddinge University Hospital, Karolinska Institutet S-141 86 Stockholm;* [2] *Trauma Laboratory, Dept. of Human Sciences, Defense Research Establishment, S-172 90 Stockholm, Sweden*

Background and Goal of Study: Penetrating trauma of the torso frequently results in injury to the large vessels leading to death from exsanguination.

Materials and Methods: Ten minutes after a 5-mm long laceration was produced in the infrarenal aorta, 16 ketamine anaesthetized pigs were randomized to receive either no fluid or a 1 minute infusion of 4 mL/kg hypertonic saline/dextran (Medisan Pharmaceuticals) The experience gained from previous studies has indicated that approximately 26 mL blood per kg body weight is lost from the circulation in this type of injury (1). The hemodynamics were studied using arterial and pulmonary artery catheters and ultra-sonic (Transonic®) flow probes placed over the portal vein, the left renal artery, and in the abdominal aorta below the renal arteries, proximal and distal to the aortic injury.

Results and Discussion: The bleeding stopped spontaneously after approximately 3 minutes (calculated as the difference between the flow rates in the upper and lower aorta) The bleeding decreased with a half-time of 41 sec. After the initial hemostasis, the bleeding started again in 6 of 8 animals receiving hypertonic saline/dextran. The total volume of blood loss amounted to 727 ± 331 mL in the control group and 1008 ± 214 mL in the treatment group The survival rate were 4 of 8 animals in the control group and 3 of 8 animals in the treated group. In all animals that died, the amount of blood loss did not differ from that in other pigs until the rebleeding started, and the animals then died due to rebleeding and consecutive shock.

The results of our study may have implications to the treatment of penetrating intra-abdominal injuries with suspected large-scale haemorrhage. The intravenous infusion of hypertonic saline/dextran rapidly increased the blood pressure and the start of rebleeding, resulting in an increased mortality. It therefore seems very important to give definitive treatment in the hospital within 30 min of the initial treatment with hypertonic saline/dextran.

Conclusion: Hypertonic saline/dextran fluid therapy improved the hemodynamic status but increased the risk of rebleeding

A.567 Atypical clinical features of acute aortic dissection in an emergency department

J.P. Goarin, P Ruel, M. Gosgnach, B Riou, P Coriat. *Pitié Salpêtrière, Paris*

Background & Goal of the Study: It is admitted that the classical clinical presentation of aortic dissection is a sudden chest pain which occurs in 95% of the cases[1] But the symptoms seem extremely variable The goal of the study was to describe the different clinical manifestations of acute aortic dissection and to draw attention on the atypical forms

Patients & Methods: We reviewed all the acute aortic dissections diagnosed at the admission in the surgical intensive care unit over a six-year period. All the symptoms participating to the initial clinical presentation were recorded

Results: Among 71 patients admitted in the emergency department, 9 had a chronic aortic dissection and 59 shows acute symptoms All symptoms and atypical clinical features which could lead to an erroneous diagnosis are depicted in the table Classical chest pain was present in only 60% of the cases In 25% of the cases, pain was purely abdominal. 1 of these patients showed an elevation of the ST segment on EKG and 1 epigastric pain was relieved by nitroglycerine In 3 cases (2 strokes and 1 spontaneous paraplegia) the patients had isolated neurologic symptoms In 2 cases patients had congestive heart failure (CHF) with pulmonary oedema, related to acute aortic regurgitation 2 patients were admitted for unexplained shock 1 have been operated for an acute limb ischemia simulating arterial embolism This patient developed also a severe hypercapnia resulting from a mediastinal compression of right pulmonary artery and left main bronchus

Clinical manifestations

Symptoms	Incidence (n)	
	Total*	Atypical
Chest pain	37	0
Abdominal pain	21	15
Pericardial effusion	7	0
Shock	6	2
CHF	2	2
Stroke	3	2
paraplegia	6	1
Limb ischemia	2	1

* A patient could have several symptoms

Conclusion: Acute aortic dissection could be frequently ignored because of the missing classical chest pain. Non typical clinical manifestations are frequent (39%) and could lead to inadequate treatment

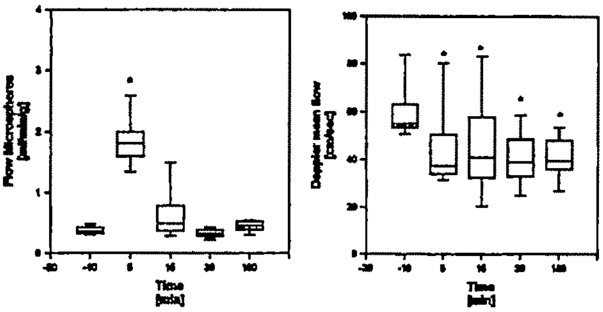
A.568 Transcranial Doppler in resuscitation: pathological cerebral perfusion after CPR and delayed return of spontaneous circulation

M. Schmidt[1], B Dirks, K.H. Lindner[2] [1] *Dept. of Anesthesiology/University of Ulm, Germany,* [1] *University of Innsbruck, Austria*

Background and Goal of Study: Monitoring of intracranial hemodynamics using transcranial Doppler-Sonography (TCD) may give information to optimize therapy after cardiopulmonary resuscitation (CPR) to avoid ischemic cerebral injury. The effects of cardiac arrest and CPR on cerebral blood flow (CBF) and TCD flow patterns were studied, especially after delayed return of spontaneous circulation (ROSC)

Materials and Methods: After approval by the local animal investigation committee 8 domestic pigs (23–30 kg) were investigated under general anesthesia. Before ($t_0 = -10$ min) cardiac arrest of 4 min, closed chest CPR of minimum 5 min and at $t_1 = +5$, $t_2 = +15$, $t_3 = +30$, $t_4 = +180$ min after ROSC TCD mean flow, Pulsatility Index (P.I.), Resistance Index (R.I.), CBF (microspheres), CO (thermodilution), HR, MAP, EEG and arterial blood gases were determined. The duration of CPR was depending on the time ROSC could be achieved.

Results and Discussion: Due to cardiac arrest electrical activity came to baseline within 45 sec 5 min after ROSC (t_1) CBF showed a significant increase ($p < 0.05$), as TCD mean flow decreased significantly ($p < 0.05$) compared to baseline (to) Under normoventilation CBF was normalizing at t_2 +15, t_3 +30 and t_4 +180, but TCD mean flow stayed significantly



deminuted. CO increased significantly at t_1+5 and stayed normal from t_2+15 until t_4+180. P.I. increased more than it would be expected by chance at t_1 +5, t_2 +15 and t_3 +30. Depending on short time CPR (group1) or long time CPR (group2) there is a significant difference ($p < 0.01$) in P.I.

Conclusions: Increased CBF, decreased TCD mean flow and increased P.I. after ROSC indicate an increase in intra-cranial pressure due to vasogenic brain edema depending on duration of CPR detected by Transcranial Doppler.

A.569 Effect of trauma and cisapride on gastric emptying

Frances Conway. *Royal College of Surgeons in Ireland, Beaumont Hospital, Dublin, Republic of Ireland*

Introduction: The proposed mechanisms for the delay in gastric emptying following trauma are difficult to study in a controlled manner in a human population. Prokinetic agents have been shown to increase GE in volunteers and experimental models. Cisapride (C) has been shown to increase gastric emptying in a rat model.(1) We investigated the effect of trauma and C, alone and in combination on GE in an animal model.

Methods: Twenty four male Sprague Dawley rats (weight 290–310 g) were fasted overnight. They were anaesthetised with ketamine 75 mg/kg and acepromazine 2.5 mg/kg i.m. A 22G iv cannula was inserted in a tail vein and 10 ml/kg 0.9% saline was given. Rectal temperature was monitored and normothermia maintained using an overhead heater. Gastric emptying was assessed in terms of % of a test meal emptied over one hour.(2) At time 0 a test meal of 3 ml (of known weight) was given via an orogastric tube. The animals were randomised into three groups of eight. Group 1 (controls) – no trauma, Group 2 – trauma immediately after feed (femoral fracture) and Group 3 trauma/and cisapride 3 mg/kg i.p 15 minutes later. All animals were euthanized one hour post feed and laparotomized. The stomachs were removed, weighed on an analytical balance then cut open, rinsed and weighed again. The % test meal emptied from the stomach in one hour was calculated for each group. Dunnetts Method was used to assess differences between the mean value for GE in the control group and groups 2 and 3 and comparisons for all pairs were made using Tukey-Kramer HSD. (alpha = 0.05)

Results: Results are expressed as mean ± SEM (table 1)

Group	% meal emp	SD	SEM
Control	83 375	4 1036	1 4508
Trauma	50 625	7 4438	2 6318
TR + CIS	77 9262	16 1426	5 7073

Gastric emptying was significantly decreased in the trauma group compared to control and the trauma/cisapride group There was no significant difference between control and the trauma/cisapride group.

Conclusions: Trauma delays gastric emptyingin this animal model and cisapride reverses this effect. This may have an application in the preoperative management of the trauma patient This study supports the contention that prokinetic agents promote gastric emptying in trauma.

A.570 Emergency medicine on the Internet

P. Lierz, P. Fellerter. *Dept of Anaesthesiology and General Intensive Care Medicine B, University of Vienna, Austria*

Current developments in medicine led to a large number of modern information systems Beside traditional printed and audiovisual media, working with computers is of increasing importance. Off-line systems (e.g. CD-ROM) and on-line systems are available. Easy access from workplaces in the office or at home, low costs and a wide range of information brought the Internet into the centre of interest during the last years. Providers of medical information include publishers of journals, organisations, universities and hospitals, hosts of congresses, physicians, industrial companies and commercial information providers. Many of these pages are of interest for the physician working in the field of emergency medicine. But the huge amount of data available on the Internet is not only of interest, it is also the source of a major problem with this on-line information system. How do you find what you are looking for?

Search engines find up to 10,000 pages somehow related to the topic of emergency medicine. To select the major sites providing information for the physician working in emergency medicine we used refined search criteria and selected the most interesting homepages Links to these sites are available at our homepage http://mailbox.univie ac at/~a5831mhc/ems html/ and can be easily accessed worldwide. All recommended sites are listed with short descriptions of their contents.

A.571 Aspiration in trauma

D. Lockey[1], T. Coats[1], M. Parr[2]. [1]*Helicopter Emergency Medical Service, Royal London Hospital, London,* [2]*Frenchay Hospital, Bristol, UK*

Background and Goal of Study: Victims of major trauma are assumed to be at high risk of aspiration of gastric contents Whether the risk of aspiration comes from blood and debris from the upper airway or gastric contents, has not been determined. Determining where the major risk lies has implications for airway management We have examined the incidence and nature of aspiration in a group of trauma patients

Methods: 53 consecutive patients with major trauma who required pre-hospital endotracheal intubation by members of the Helicopter Emergency Medical Service in London were studied prospectively At direct larangoscopy the presence, amount (small, moderate, large), and nature of contamination visible around the vocal cords was recorded Post-mortems looking specifically for evidence of aspiration were requested on 17 patients who died within 4 hours of injury.

Results: There were 42 male and 11 female patients. Mean age was 41 (range 16–80) 44 (83%) had head injuries 29 had a Glasgow coma score of 3 and 39 scored 8 or below 21 survived and 32 died. 18 (34%) of patients had evidence of contamination at laryngoscopy. 15 had blood/debris from the upper airway and 3 had gastric contents. Of the 10 post mortems performed one confirmed aspiration of gastric contents, one confirmed aspiration of blood, 7 confirmed that no aspiration had occurred and one showed no evidence of aspiration where a moderate amount of blood had been seen at intubation.

Discussion: Contamination of the vocal cords was common but was mostly from the upper airway rather than gastric contents This is consistent with the findings of a study of 17 trauma patients who aspirated (1) Where a definitive airway (i.e. cuffed tracheal tube) is indicated but cannot be provided, a device which provides some protection from upper airway soiling (e g. the laryngeal mask airway) would be more appropriate than the conventional oropharyngeal airway which offers no protection from aspiration from debris from the upper airway (2).

A.572 Prehospital tracheal intubation: a retrospective study of compliance with a set of criteria

Isabelle Fleisch, Eric Buchser, Olivier Moeschler. *Anaesthesiology department, CHUV, Lausanne, Switzerland*

Introduction: Tracheal intubation before the admission to an emergency room is a key factor in the management of severely ill or traumatised patients. However, since this procedure is often performed by junior physicians, the indication for tracheal intubation has to be carefully standardised

Objective: The aim of this study was to evaluate the degree of compliance with a proposed set of criteria for tracheal intubation, in the prehospital management of severely ill or traumatised patients.

Methods: Patients over 16 years of age, intubated within fifteen minutes upon admission at the hospital were analysed retrospectively. Failure to comply with the proposed criteria and the reasons for intubation upon admission in the emergency room were reviewed

Results: During a 30 months period, from the 1st January 1995 to the 30th of June 1997, 4233 patients were admitted to our emergency room, 20.1% were transported by helicopter and 79.9% by ground transportation Prehospital intubation was performed in 555 cases (13 1%), while failure to intubate the patient occurred in 15 patients (2.7%). Among those, 10 died before admission.

Among patients we were not intubated at admission, 26 (0.7%) required emergency tracheal intubation immediately upon admission at the emergency room Reasons for emergency tracheal intubation upon admission included a) unsuccessful attempt to intubate the trachea at the site of injury (n = 5), b) worsening of the patient's condition (n = 8), c) information from additional investigation (n = 5), and d) inadequate evaluation at the site of injury (n = 8)

Conclusion: The number of patients for whom the proposed criteria for prehospital tracheal intubation were overlooked is small (0.18%). The decision not to intubate was made deliberately in all cases and can be regarded as mismanagement.

We therefore believe that the proposed criteria for prehospital tracheal intubation do no need to be changed since they allow for adequate management of the vast majority of severely ill or traumatised patients.

A.573 Survival of trauma patients who have prehospital endotracheal intubation without anaesthesia or muscle relaxants

D Lockey, R Craig, G Davies *Royal London Hospital, London, UK*

Background: In the UK it is current practice for paramedics to perform endotracheal intubation on trauma patients when the airway is compromised and basic airway manoeuvres fail Anaesthetic drugs and muscle relaxants are not used. We have investigated the outcome in a population of trauma patients who are intubated in the pre-hospital environment without drugs.

Methods: We looked retrospectively at the database of a physician led helicopter emergency medical service dedicated to trauma patients. We identified patients that had been intubated without drugs by paramedics and doctors and recorded whether they survived to hospital discharge.

Results: In a six year period 680 patients were intubated and airlifted from the scene. Data was available on 678 566 received anaesthetic drugs and/or muscle relaxants and 94 received none. One patient in the no drug group survived (1%). He had suffered a cardiac arrest after penetrating chest trauma and had an on scene thoracotomy to relieve pericardial tamponade.

Discussion: There is little evidence that endotracheal intubation improves the outcome in cardiac arrest patients (1, 2, 3). Our results suggest that this may also be the case for victims of trauma as virtually all patients intubated outside hospital without drugs died. In UK paramedic practice, non-drug assisted endotracheal intubation is a major part of extended training. The value of this intervention deserves further scrutiny.

A.574 Resuscitation from cardiac arrest with adrenaline or vasopressin: systemic and regional effects during the post-resuscitation period in rats

W. Studer, X. Wu, M Siegemund, M Seeberger *Department of Anaesthesia and Research, Kantonsspital, University of Basel, CH-4031 Basel, Switzerland*

Background & Goal of Study: Using vasopressin (AVP) instead of epinephrine (EPI) improves vital organ perfusion (1) during resuscitation, but depression of myocardial function during the postresuscitation period (2) has been reported. Whether the mesenteric perfusion is affected, is unknown. We therefore determined jejunal mucosal PCO2 before cardiac arrest (CA) and 60 min after return of spontaneous circulation (ROSC)

Methods: 28 rats (450–500 g) were anaesthetised, ventilated, invasively monitored and a 5 Fr. paediatric tonometer was inserted into the jejunal lumen Precordial chest compression (PCC) at a rate of 200/min, using a thumper (Michigan Instruments) was started 4 min after onset of AC induced ventricular fibrillation (VF), continued for 4 min and followed by transthoracic DC defibrillation with 5 J. After 5 min of VF the rats randomly received AVP (0 8 U/kg) or EPI (90 μg/kg) i.v. Before CA and after 60 min of ROSC, right atrial oxygen saturation (SvO2) (OSM 3), arterial lactate (YSI 2300), arterial pH, PCO2 and tonometric PCO2 (PtCO2, IL 1302) were measured. PCO2 gap and pHi were calculated using standard formulas. Group means ± SD were analysed using Student's t-test.

	Before CA		60 min ROSC		
	EPI	AVP	EPI	AVP	p
MAP mmHg	146 ± 20	140 ± 18	87 ± 15	99 ± 12	0.058
SvO2 %	78 ± 7	73 ± 5	54 ± 8	63 ± 5	0 004
Lactat mmol/L	1.3 ± 0 2	1.1 ± 0.2	3 4 ± 0.7	2 5 ± 1 4	0.142
pH art	7.36 ± 0 03	7 37 ± 0 04	7 23 ± 0 06	7 25 ± 0 10	0 512
PtCO2 mmHg	56 ± 6	54 ± 3	73 ± 7	65 ± 7	0 035
PCO2 gap	17 ± 5	17 ± 3	34 ± 7	24 ± 10	0 059
pHi	7 21 ± 0 04	7 21 ± 0.03	6 97 ± 0.06	7 05 ± 0 08	0.049

Results (table) AVP and EPI increased coronary perfusion pressure during resuscitation to similar levels (48 ± 14 vs 40 ± 10 mmHg). 7 of 14 (AVP) vs. 12 of 14 (EPI) rats were successfully resuscitated (p = 0.132, Fisher's exact test).

Conclusions: Higher SvO2, lower PtCO2 and higher pHi might indicate that the use of AVP during resuscitation is associated with better systemic oxygenation and less mesenteric ischemia in the early postresuscitation period Whether this is due to increased perfusion, remains to be cleared

A.575 Diagnostic value of troponin T as a biochemical marker of myocardial contusion

M. Helm, J Hauke, L Lampl, K H Bock. *Dept of Anaesthesiology and Intensive Care Medicine Federal Armed Forces Medical Center Ulm, 89070 Ulm, Germany*

Background and Goal of Study: The diagnostic delimitation of myocardial contusion is difficult because of nonspecifity of diagnostic tests Circulating cardiac troponin T (cTnT) is considered a highly sensitive and specific marker of myocardial cell injury [1] The purpose of this study was to investigate the value of cardiac troponin T (cTnT) measurement as a biochemical marker in the diagnosis of myocardial contusion

Material & Methods: Prospective study, involving one hundred-twenty-five (125) trauma victims (92 male, 33 female; age: 35.4 ± 19.2 years; ISS· 23 4 ± 16 0), who were admitted to our hospital during an one year period (01 10 1995–31 10 1996) In all patients the following diagnostic screening was performed: 12 lead ECG and transthoracic echocardiography at hospital admission (time "A"), CK and CK-MB as well as quantitative cTnT measurement at hospital admission (time "A"), after completion of diagnostic phase (time "B") and 24 h after hospital admission (time "C") Additionally, a qualitative cTnT bedside-test (TropT™, cut-off: 0.2 μg/l, test result within 20 min) was performed at time "A" and "B"

Results & Discussion: In 14 4% of the cases, Trop™-test was positive, there was a statistically significant correlation between the quantitative cTnT measurement and TropT™-test results ($p < 0.001$; sensitivity 1.0/0.86 – specifity 0.89/0.94 at time "A"/"B"). In 60.8% of the cases, a positive CK-MB/CK index (>5%) was found, but there was no correlation to quantitative and qualitative cTnT measurements The relationship between TropT™-test/CK-MB/CK index and TTE/12-lead ECG is shown in the following table:

	TTE		ECG	
	pathol	Normal	pathol	normal
TropT™ positive	2	13 ns	3	9*
TropT™ negative	9	83 ns	5	101*
CK-MB/CK positive	9	58 ns	5	65 ns
CK-MB/CK negative	2	38 ns	3	45 ns

*p < 0 008

Conclusion: Even in the early phase after trauma, cTnT has proven itself as a sensitive and specific biochemical marker of myocardial cell injury. Of clinical value is the qualitative TropT™-test.

A.576 Prehospital care and survival in paediatric blunt trauma

P Suominen[1], C. Baillie[2], A Kivioja[3], R. Korpela[4], R. Rintala[2], T. Silfvast[1], K.T. Olkkola[1]. *[1] Department of Anaesthesia; [3] Department of Orthopaedics and Traumatology, Helsinki University Central Hospital; [4] Department of Anaesthesia; [2] Paediatric Surgery, Hospital for Children and Adolescents, Helsinki, Finland*

Background: The aim of this study was to compare the outcome of severe blunt trauma in children receiving prehospital care from either physician-staffed advanced life support (ALS) units, or from basic life support (BLS) units staffed by emergency medical technicians

Methods: The records of 288 children with severe blunt trauma who required intensive care in the regional level 1 trauma center, or who died from their injuries, were analysed retrospectively Patients were excluded if resuscitation at the scene was not attempted, if the level of prehospital care was unspecified, or if arrival at the level 1 trauma center was delayed beyond 150 minutes. Seventy-two patients met the inclusion criteria of BLS-, and 49 the criteria of ALS-prehospital care.

Results: A reduced mortality (22.4% vs. 31.9%) was seen in ALS group, which was more apparent in a "salvageable but high risk" subgroup, characterized by Glasgow Coma Scale (GCS) 4–8, Paediatric Trauma Score (PTS) 0–5, and Injury Severity Score (ISS) 25–49. However, a statistically significant difference was only seen when trauma severity was evaluated by the ISS.

Mortality and measures of injury severity

Measure		ALS group %	BLS group %	P-value
Overall mortality		22 4	31 9	NS
GCS	3	100	100	
	4–8	23 5	36 4	NS
	9–15	0	2 3	
PTS	<0	75 0	100	
	0–5	38 1	54.2	NS
	6–12	0	2.9	
ISS	<25	0	2 6	
	25–49	24 0	54 5	0 040
	50–75	100	83 3	

The trauma scores are were calculated on hospital arrival

Conclusion: An improved outcome in children with severe blunt trauma has been demonstrated when prehospital care is provided by physician-staffed ALS units compared with BLS units

ACUTE AND CHRONIC PAIN MANAGEMENT

A.577 Serotonin sensitizes primary afferent nociceptors to bradykinin

T. Meuser, P Pierce Palmer. *Dept. of Anesthesia, University of Cologne, Cologne, Germany; Dept. of Anesthesia, University of California, San Francisco, USA*

Background & Goal of Study: Serotonin (5-hydroxytryptamine, 5-HT) is known to produce pain and hyperalgesia in the peripheral nervous system [1]. The method of spinal cord dorsal horn c-Fos immunohistochemistry has been shown to be a reliable marker for neuronal activity following noxious stimulation of primary afferent nociceptors [2]. The purpose of this study was to determine if bradykinin-induced dorsal horn c-Fos is enhanced after pretreatment with 5-HT at a concentration (10^{-6} M) which alone does not stimulate c-Fos expression

Materials & Methods: After institutional approval experiments were performed on anesthetized adult male Sprague-Dawley rats (weight 365–385 g). 100 μl each of either 5-HT 10^{-6} M, bradykinin 10^{-5} M, 5-HT 10^{-6} M + bradykinin 10^{-5} M or saline (control) was injected in rat left knee joints (n = 4 rats per treatment group). After 90 minutes the lumbar spinal cords were removed and immunostaining, according to the avidin-biotin peroxidase method of Hsu et al. [2], was performed on 45 μm spinal cord sections with a specific antibody to the c-Fos protein. Fos-like immunoreactivity was studied through L2 and L3 spinal segments by counting Fos-positive nuclei in the dorsal horn and taking ratios between ipsi- and contralateral sides Results are presented as mean ± SD and statistical one-way analysis of variance was used to compare the different groups.

Results: 5-HT alone did not show a statistically significant difference compared to control ($p = 0.744$), whereas bradykinin was significantly different from control (2.9 ± 0.7 vs. 1.2 ± 0.2, $p < 0.001$) and 5-HT administered together with bradykinin was significantly different from bradykinin alone (4 9 ± 1.0 vs. 2.9 ± 0.7, $p = 0\ 001$).

Conclusion: We have demonstrated that 5-HT enhances bradykinin-induced spinal c-Fos expression and possibly induces hyperalgesia by sensitizing nociceptors to chemically noxious stimuli in the rat knee joint. Additional pharmacological studies are being performed to determine the specific receptor subtype(s) involved in 5-HT-induced hyperalgesia.

A.578 Effect of intrathecal agmatine on morphine-induced spinal analgesia in rats

Gy Horváth[1], M. Szikszay[1], W. Klimscha[2], I. Dobos[1], G. Kékesi, G. Benedek[1], J. Eisenach[3]. [1] *Dept. of Physiology. A. Szent-Györgyi Med Univ., Szeged, Hungary;* [2] *Dept. of Anesthesia and Intensive Care Unit, Vienna, Austria;* [3] *Dept. of Anesthesiology, The Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, North Carolina, USA*

Background & Goal of Study: Agmatine is a primary amine recently discovered to be a clonidine-displacing substance, which is the endogenous ligand of alpha-2-adrenergic and imidazoline-receptors (1). It is well known that the intrathecal (IT) administration of clonidine which binds the alpha-2 adrenergic and imidazoline-receptors as well, results in antinociception and potentiates morphine-induced analgesia The purpose of the study was to investigate the possible antinociceptive effect of IT agmatine, and its interaction with IT morphine in inflammatory pain tests in rats

Materials & Methods: After institutional ethical approval intrathecal catheters were implanted, and two series of experiments were performed In single agonist studies, animals received agmatine (50 μg or 100 μg) before (pretreatment) or after (posttreatment) the carrageenan-induced inflammation Paw withdrawal latencies were obtained before carrageenan, 3 h after carrageenan, then 30 60 and 90 minutes later. In the second series rats received IT morphine (in cumulative doses of 1 μg, 4 μg and 5 μg) together with agmatine pretreatment or posttreatment Paw withdrawal latencies were determined 10 and 30 min after the morphine injections Groups were compared by ANOVA with $P < 0.05$ considered significant.

Results & Discussion: IT agmatine pretreatment dose-dependently decreased carrageenan-induced hyperalgesia and potentiated morphine-induced antinociception. Agmatine posttreatment alone caused a slight decrease in the hyperalgesia, but the higher dose significantly increased the efficacy of the lowest dose of morphine.

Conclusion: Based on the results obtained in this study, we conclude that the spinal administration of the endogenous ligand has beneficial effect on morphine-induced antinociception

A.579 Drug interaction of intrathecal carbachol and clonidine in neuropathic pain model in the rat

J.H. Hwang, E J Lee, S M Han, D M Lee. *Department of Anesthesiology, University of Ulsan, Asan Medical Center, Seoul, 138-736, Korea*

Background: Peripheral nerve injury may generate a syndrome of events (spontaneous pain, allodynia and hyperalgesia), that includes poor response to morphine and dependency of this pain state on intact sympathetic function Spinally delivered α2-adrenoceptor agonist and cholinergic agonist or cholinesterase inhibitors each have been shown to have actions attenuating the hyperalgesia in rat models.

Using an isobolographic analysis (1), We examined the spinal interaction between the α2-adrenoreceptor agonist clonidine and cholinergic agonist carbachol in a rat model of neuropathy.

Methods: Male SD rats were prepared with tight ligation of left lumbar 5 & 6th spinal nerves (2) and chronic lumbar intrathecal catheters Intrathecal dose-response curves were established for the antiallodynic effect of carbachol (0 1, 0 3, 1 0, 3 0 mg) and clonidine (0 3, 1.0, 3 0, 10 mg) alone to obtain the ED50 for each agent (fig 1). ED50 fractions (1/2, 1/4, 1/8, 1/16) of drug combinations of carbachol-clonidine were administered and thresholds for left hind limb paw withdrawal to von Frey hair application were assessed and converted to MPE. The ED50 of carbachol-clonidine combination was established and isobolographic analysis of the drug interactions was carried out.

Results: Intrathecal carbachol and clonidine alone produced dose-dependent reductions of tactile allodynia· ED50 66 ng (12–367 ng) and 39 ng (1–1452 ng), respectively. The log dose-responses were plotted from the peak effect of %MPE in each group of carbachol and clonidine (fig 1). The experimental ED50 (point B) for carbachol-clonidine mixture was found to be significantly below the theoretical additive ED50 (point A) (fig 2).

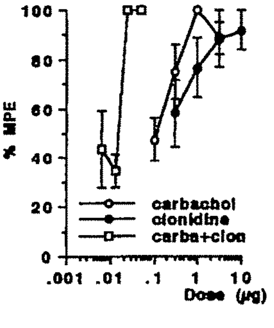

Fig 1 Dose response curves

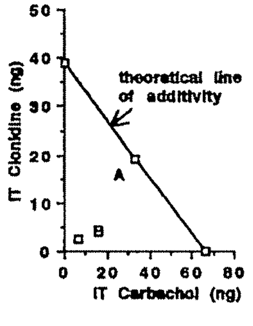

Fig 2 Isobolograph for synergism

Conclusion: The experiments suggested that intrathecal carbachol and clonidine alone produce a dose dependent antagonism on touch evoked allodynia and intrathecal carbachol is synergistic in the spinal level when combined with intrathecal clonidine in a rat model of neuropathy

A.580 Comparison of morphine and tramadol in an animal model of trigeminal neuropathic pain

E. Hendrickx, B.P. Vos[1], G. Hans[1], K. Vissers, R. Heylen, H. Adriaensen[1].
[1]Ziekenhuis Oost-Limburg, Genk; University of Antwerp, Belgium

Aim: The unique pharmacological features of Tramadol, an opiate-like analgesic, could make Tramadol the drug of choice for treatment of neuropathic pain syndromes. This assumption was evaluated in an animal model of trigeminal neuropathic pain, comparing Morphine to Tramadol administration

Methods: The experimental set-up consisted of six phases: acclimatisation, preoperative testing, surgery and development of the neuropathic pain syndrome, postoperative testing to assess trigeminal hypersensitivity and opiate analgesic effect, development of opiate tolerance, and finally postoperative testing to assess tolerance and cross-tolerance. The trigeminal neuropathic pain model is based on a chronic constriction injury to the infra-orbital nerve (Ion-CCI). Twenty-nine Sprague-Dawley rats received such a unilateral injury; ten control rats received unilateral sham-surgery. The presence of mechanical hypersensitivity was assessed using a mechanical stimulation test.

Results: Rats with an Ion-CCI showed hyperresponsiveness to a range of von Frey hair stimulations which was reduced both by Tramadol and Morphine. In sham-operated rats, the ratio between equi-analgesic doses of Morphine and Tramadol was 1/4.5 (ED50 3.23/14.1). Interestingly, in Ion-CCI rats this ratio was about 1/2 (ED50: 13.04/29.1). The effect of Morphine and Tramadol was predominantly reversed by Naloxone. Repeated Morphine administration led to the development of Morphine tolerance, but no cross-tolerance to Morphine was found after repeated Tramadol treatment. A 'lack of tolerance and cross-tolerance development' to Tramadol was observed.

Discussion: It is possible that, at the early postoperative time point, thanks to its combined opioid-non-opioid mode of action, the effect of Tramadol is only partly attenuated by the reduction of the opioid receptor responsiveness and the non-opioid mode of action remains fully efficient. Tramadol's inhibitory effect on the serotonine uptake could be responsible for this effect and might also be responsible for the relative lack of tolerance and cross-tolerance to Tramadol. Later in the postoperative period it is possible that the (−) enantiomer of Tramadol counteracts the analgesic effect of the (+) enantiomer at this later stage.

Conclusion: At the early postoperative time point, Tramadol had a relatively greater potency than Morphine to suppress the hyperresponsiveness in neuropathic pain conditions. At the late postoperative time point, the efficiency of Tramadol was reduced.

A.581 Experimental pain testing: how reproducible are the results?

M. Luginbühl[1], S. Petersen-Felix[1], L. Arendt-Nielsen[2], A.M. Zbinden[1].
[1]Department of Anaesthesiology and Intensive Care, Inselspital, Berne, Switzerland; [2]Center for Sensory-Motor Interaction, University of Aalborg, Denmark

Background and Goal: Although experimental pain tests are widely used to test analgesic effects of drugs[1] or to assess pain susceptibility of individuals[2] there hardly exist any data on their reproducibility. We assessed the reproducibility of five different pain tests when performed on three different days on the same person and determined the circadian and inter-individual variation.

Methods: 6 female and 5 male healthy volunteers in the age of 22–26 years were tested on three separate days at the same day time with at least 48 hours apart. On Study day 1 two additional sessions were held at least 3 hours apart to assess circadian variability. The following experimental pain tolerance tests were applied: *Ice water pain*[2], maximal exercise *tourniquet ischaemia pain, pressure pain, heat pain* and *electrical pain* as well as *the reaction time* to acoustical signals. Maximal duration and pain rating by visual analogue scale (VAS) was continuously registered for the ischaemia and cold pain test with the area under the VAS vs. time curve (AUC) representing the perceived pain. After a trial testing to familiarize the volunteers with the procedure two test series were performed 15 minutes apart in each session. Coefficient of variations between the sessions were calculated for every volunteer and every test.

Results and Discussion: The mean coefficients of variation (standard deviation) of day-to-day, circadian and inter-individual variation are summarized below

	Day-to-day	Circadian	Inter-individual
Electrical Pain	0.31 (0.16)	0.15 (0.10)	0.38
Pressure Pain	0.09 (0.08)	0.09 (0.05)	0.22
Heat Pain	0.06 (0.02)	0.03 (0.02)	0.08
Ischaemic Pain	0.13 (0.09)	0.10 (0.10)	0.28
Cold Pain	0.11 (0.09)	0.10 (0.08)	0.22
Reaction Time	0.14 (0.08)	0.07 (0.05)	0.24

Electrical pain performed worst with an almost equal intra- and inter-individual variability probably due to a variable skin impedance. Heat pain tolerance, although best reproducible, hardly varies within the population.

Conclusions: Pressure Pain, followed by ischaemic and cold pain are best suitable to assess pain tolerance of an individual. The impact of circadian variation is probably negligible.

A.582 Individual pain tolerance cannot be assessed by a single pain test

M. Luginb0hl[1], S. Petersen-Felix[1], L. Arendt-Nielsen[2], A.M. Zbinden[1]
[1]Department of Anesthesiology and Intensive Care, Inselspital, Berne, Switzerland; [2]Center for Sensory-Motor Interaction, University of Aalborg, Denmark

Background and Goal: Cold Pain can be used to discriminate pain tolerant and pain susceptible individuals[1]. The aim of this study was to determine whether pain tolerance to one pain modality also implies pain tolerance to others. Thus four other experimental pain tests were compared with cold pain tolerance with regard to inter-individual variation and concordance between the tests.

Methods: 7 female and 8 male healthy volunteers in the age of 22–28 years were tested on three separate days at corresponding day time with at least 48 hours apart. Pain tolerance to the following experimental pain models were determined. *Ice water pain*[1], maximal exercise *forearm tourniquet ischaemia pain, pressure pain, heat pain* and *electrical pain*[2]. Reaction time on acoustical signals was measured as well. Maximal duration and pain rating by visual analogue scale (VAS) was continuously registered for the ischaemia and cold pain test with the area under the VAS vs. time curve (AUC) indicating the perceived pain. Sperman rank order correlation was used to calculate the correlation coefficient for all the pairs of tests with $p < 0.05$ considered significant. A histogram of the results for every test was used to describe the distribution of pain susceptibility in the test population.

Results and Discussion: Ischaemic pain susceptibility significantly correlated with cold pain ($r = 0.52$, $p = 0.046$) and (inversely) with heat ($r = -0.507$, $p = 0.051$) and pressure ($r = -0.582$, $p = 0.022$) pain tolerance. Heat and pressure pain tolerance were additionally correlated (0.696, $p = 0.003$). Electrical pain and reaction time were not significantly correlated with other tests. The AUC of cold and ischaemic pain revealed a bi-modal distribution within the population, whereas paintolerance as assessed by the other tests appeared normally distributed. In 7 of 15 volunteers the paintolerance results were not consistent between the five tests. Ischaemic and cold pain tolerance, that may allow discrimination between pain tolerant and susceptible individuals, were discordant in 3 of 15 volunteers.

Conclusions: The pain susceptibility is highly depented of the pain modality used. There is complete discordance from one test to another in many individuals despite a statistically significant correlation of pain tolerance between some tests.

A.583 Effect of intravenous propofol on thermal pain thresholds

K. Liao, M. Liu, M. Monteforte, A. Mannes, T Kramer, F.M. Ferrante *Univ of Pennsylvania, Dept of Anesth, USA*

Introduction: Propofol's analgesic properties remain controversial. Propofol in subhypnotic doses in adults has been shown to have an analgesic effect on somatic pain (1, 2). However others have found that propofol in sedative doses had no analgesic effect, although the reaction time was prolonged at the higher doses. In rats, propofol has been shown to have both an anti-analgesic and no anti-analgesic effect at subhypnotic doses.

The aim of this study was to investigate whether subhypnotic doses of propofol affected somatic pain thresholds. The combination of propofol in a subhypnotic infusion with thermal stimulation has never been studied before. We chose thermal stimulation as the pain stimulus because it is generally considered to produce the purest monomodal nociceptive stimulus.

Methods: This double-blinded placebo controlled randomized study was approved by our Institutional Review Board. Ten healthy volunteers were tested after familiarizing themselves with the testing procedures and stimuli. The 4 modalities tested were cold threshold, warm threshold, cold-induced pain threshold, and heat-induced pain threshold. Each modality was administered separately and randomly. Baseline temperature of the thermode was 32°C. The thermode delivered heat or cold stimuli to the subject's skin. Stimulation was discontinued by pushing a button. The thermode temperature changed at a rate of 0.7°C sec^{-1} (maximum 50°C, minimum 0°C) with 50 to 55 seconds between pain stimuli. Intravenous propofol doses were randomly administered to produce a constant effective site concentration of 0.0 (lipid emulsion), 0.2, 0.4, and 0.8 μg·ml^{-1} with a STANPUMP. Propofol was allowed to clear from the effective site for 30 minutes between cycles. Reaction time was tested by pressing a button in response to an audio signal ANOVA with repeated measures was used for analysis

Results: There was no statistically significant change in warm or cold detection threshold or heat or cold pain threshold Reaction time was not affected at the tested doses.

Discussion: The results suggest that propofol at subhypnotic concentrations does not have an analgesic or anti-analgesic effect Propofol also does not affect warm or cold threshold

A.584 Gabapentin in chronic neuropathic pain (preliminary results)

C Suan, F Martínez-Calderón, J Fernández, R Cobos, C Pérez-Torres, A. Herrera *Hospital Universitario Virgen del Rocío, Seville, Spain*

Background & Goal of Study: Anticonvulsant (ACD) and antidepressant drugs are used in combination for the treatment of chronic neuropathic pain Gabapentin, which has been reported to be effective in many kinds of neuropathic pain, may replace the older ACD due to the extremely low side-effect profile(*). The aim of the study is to analyse the use of gabapentin in a pain clinic during a year

Methods: Clinical records of patients who initiated treatment with gabapentin during the last year have been reviewed Several aspects have been analysed. Analgesic outcome assessment was made according to discharge, any improvement, no change, or impairment.

Results: 49 patients initiated treatment with gabapentin 63.26% were male. The mean age was 62.10 years Painful diseases were postherpetic neuralgia (21 cases), trigeminal neuralgia (7), central pain (7), phantom limb pain (4), postoperative or posttraumatic neuralgia (4), reflex sympathetic dystrophy (2), oncologic neuralgia (2), diabetic neuropathy (1) and stump pain (1) Only 6 patients were given gabapentin as first step treatment 43 patients received gabapentin after the initial analgesic therapy had failed. 77.55% of the patients showed clinical improvement (9 were discharged), 20.40% manifested no change and only 1 patient showed clinical impairment Of 21 patients suffering from postherpetic neuralgia, 14 showed clinical improvement, 2 were discharged and 5 showed no change. Of 7 patients receiving gabapentin for central pain treatment (5 vascular lesions, 1 traumatic brain injury and 1 traumatic spinal cord injury), 3 patients improved, 1 was discharged and 1 showed clinical impairment. Of 7 patients with trigeminal neuralgia, 3 were discharged and 4 showed clinical improvement Side-effects (drowsiness and myoclonia) occurred in 10.20% of patients and forced gabapentin interruption

Conclusions: Most patients showed any clinical improvement. A minority suffered from side-effects that, although not serious, forced treatment interruption Gabapentin may be considered a valid alternative for chronic neuropathic pain treatment, but only comparative studies will be able to establish reliable differences between gabapentin and the other ACD.

A.585 Low systemic doses of ketamine reduce the temporal summation of nociceptive flexion (RIII)

X. Dupont[2], F Guinmand[1,2], D. Bouhassira[1,2], M. Chauvin[2]. [1] *INSERM U-161, Paris;* [2] *Serv. d'anesthésie, Hôp A Paré, 92104 Boulogne, France*

Introduction: In animals, both the responses of spinal nociceptive neurones and the amplitude of nociceptive reflexes increase progressively during repetitive high frequency (1–3 Hz) electrical stimulation of peripheral C-fibers. This "wind up" phenomenon which is due to the slow temporal summation of nociceptive signals in the spinal dorsal horn, is specifically reduced by NMDA antagonists such as ketamine. The aim of the present study was to evaluate in man, the effects of low systemic doses of ketamine on the central temporal summation of both the nociceptive flexion (RIII) reflex and pain sensation.

Methods: On two experimental days separated by 1 week, the RIII reflex elicited by electrical stimuli of the sural nerve at the ankle was recorded from the ipsilateral biceps femoris in 6 healthy volunteers. During each experimental day, we studied both before and after the randomized intravenous injection of 0.15 mg/kg ketamine or placebo· 1) the RIII reflex threshold; 2) the recrutement curve of the reflex up to the tolerance threshold, 3) the temporal summation of the reflex induced by repetitive electrical stimuli (frequency· 1 Hz; duration 15 s, intensity. 1.2 × the reflex threshold); 4) the modifications of pain, quantified by means of an visual analog scale, during the series of high frequency stimuli.

Results: The RIII reflex threshold, the tolerance threshold and the recrutement curve of the reflex were not significantly altered after the injection of ketamine or placebo. During the series of 15 electrical stimuli at 1 Hz, a significant increase of both the reflex responses and pain sensation was observed These facilitatory effects due to the temporal summation of nociceptive signals were significantly reduced after ketamine but not significantly modified after placebo.

Conclusion: The present results show that temporal summation of nociceptive stimuli facilitates the Aδ fibers elicited RIII reflex The effects of ketamine suggests that such a phenomenon is related to the "wind up" described in animals. Thus, the RIII reflex might constitute an interesting tool to quantify and analyse in man, the mechanisms underlying the central temporal summation of nociceptive inputs, which probably have a significant role in the pathophysiology of both acute and chronic pain syndromes

A.586 Effect of naloxone and ketamine on primary and secondary hyperalgesia in humans

S Ilkjær[1], S. Mikkelsen, J Brennum[2], F.M. Borgbjerg[3], J B Dahl [1] *Dpt Anaesth., Skejby Hospital, Aarhus University Hospital DK-8200, Aarhus N, Dpt. Anaesth., Herlev University Hospital, DK-Herlev, Copenhagen,* [2] *Dpt. Neurosurg , Rigshospitalet, Copenhagen;* [3] *The Pain Clinic, Bispebjerg University Hospital, Copenhagen, Denmark*

Background and Goal of Study: Peripheral tissue damage results in sensitization of dorsal horn neurons This is manifested clinically as allodynia and hyperalgesia (1) Injury induced sensitization of dorsal horn neurons has been implicated as an important contributor to both acute and chronic pain states (2). Ketamine binds noncompetitively to the NMDA receptor, thereby inhibiting the action of glutamate which increases spinal hypersensitivity It is not clear, whether ketamine exerts its effect solely by inhibiting excitatory amino acids, or if there is a degree of opioid interaction involved The aim of the study was therefore to investigate the effects of ketamine, with or without naloxone pretreatment, on pain and hyperalgesia after a burn injury in human volunteers.

Methods: Twentyfive male volunteers participated in the study. 1° burn injuries were induced on the right calf On 3 separate days, the subjects received a: naloxone followed by ketamine, b saline followed by ketamine, or c: saline only Pain ratings (VAS) and heat pain detection thresholds (HPDT) were determined on the burned and the unburned calf Areas of secondary hyperalgesia to punctuate and stroke stimuli around the burn injury were calculated.

Results: Ketamine reduced primary and secondary hyperalgesia with, and without pretreatment with naloxone As naloxone was injected before ketamine, a measure of opioid antagonism towards hyperalgesia was obtained Naloxone increased secondary hyperalgesia after burn injury. Side effects were frequent but clinically acceptable.

Conclusions: Ketamine, and ketamine preceded with naloxone, reduced primary and secondary hyperalgesia in a burn injury model. This is in agreement with results from previous studies (3) The response to a thermal injury seems to involve the endogenous opioid system

A.587 Hemisensory impairment indicating thalamic dysfunction in patients with reflex sympathetic dystrophy

R. Dertwinkel[1], O Rommel[2], M. Gehling[1], K. Witscher[2], M. Tegenthoff[2], M. Zenz[1], J -P. Malin[2] [1] *University Department of Anaesthesiology, Intensive Care Medicine and Pain Therapy,* [2] *University Department of Clinical Neurology BG-Kliniken Bergmannsheil Bochum, Germany*

Background and Goal of Study: Aim of this study was to evaluate the extent and quality of sensory impairment as well as other clinical features in patients suffering from Reflex Sympathetic Dystrophy (RSD)

Materials and Methods: A subtle neurological examination was performed independently by two examiners in 25 patients with chronic RSD

Results: Twenty one patients (84%) had sensory impairment attributable to RSD. In 8 patients (32%), sensory impairment was limited to the limb affected by RSD In 4 patients (16%) a sensory deficit in the upper quadrant of the body could be demonstrated. In addition, three of these patients had sensory impairment in the ipsilateral lower limb, unaffected by RSD.

In 9 patients (36%) with RSD, a hemisensory impairment could be observed which mainly affects temperature and pain sensation and was usually accompanied by allodynia in the affected limb. In six patients, allodynia was limited to the hand or foot. In others, it spreads over the whole limb and may even involve the upper or lower quadrant of the body

Conclusion: Pain seen in patients with chronic RSD might be a central pain. With respect to the hemisensory impairment we suppose that the thalamus plays a crucial role in the pathophysiology of chronic RSD. The part of the limb presenting with allodynia might be "overrepresented" in the processing of the ventral posterior nuclear group of the thalamus, whereas the remaining parts of the ipsilateral half of the body are "neglected" (1). Previously published findings (2) of unilateral decrease in thalamic activity observed with positron emission tomography in patients with chronic neuropathic pain may support this hypothesis.

A.588 Analgesic effect of adenosine on ischaemic pain in volunteers

C.P. Rae, M D Mansfield, C. Dryden, J. Kinsella. *University Dept Anaesthesia, Glasgow Royal Infirmary, Scotland*

Background: Adenosine has been shown to have some analgesic action in animal experiments. ATP has been shown to have anaesthetic sparing effect in humans. This study was designed to establish whether adenosine has analgesic actions in man

Methods: Following local ethics committee approval and written informed consent eight ASA 1, male volunteers in a double blind placebo cross-over study received either an infusion of adenosine 100 μg/kg/min for ten minutes or saline placebo under CVS monitoring. One week later the study was repeated with the alternative infusion. The painful stimulus was tourniquet induced ischaemia in the exercising arm for the last 2 minutes of the infusion. Pain measurements were made before infusion, at the end of infusion and 15 mins, 1, 4 and 24 hours later. Pain was measured using 100 mm visual analogue scores (VAS). Statistical analysis was with Wilcoxon Matched Pairs Rank Sum test. The pain scores at the end of the infusions of adenosine and saline were compared in the same subject The sum of pain intensity difference (PID) in the 24 hours after infusion was also compared

Results: Pain measured by VAS was significantly reduced in the adenosine group as compared to the saline group at the end of the infusion (see Fig. 1). There were no significant CVS changes in either group. During adenosine infusion mild facial flushing and chest tightness were observed.

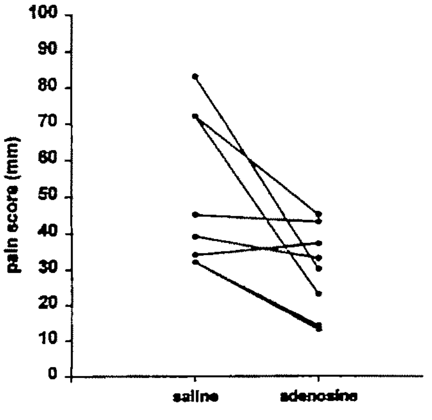

Fig 1 Pain Scores during Saline and Adenosine Infusions Median Difference 20 8 95% C I. 2.0–40.

Conclusions: Adenosine appears to have measurable effects on ischaemic pain but side effects may limit the clinical usefulness.

A.590 Intravenous testing of opioid sensibility in patients with chronic non-cancer pain and consecutive oral adjustment of pain medication

R Dertwinkel, M Strumpf, A. Willweber-Strumpf, B. Bading, M. Tryba, M. Zenz *University Dept. Anaesthesiology, Intensive Care Medicine and Pain Therapy, BG-Kliniken Bergmannsheil Bochum, Germany*

Background and Goal of Study: An intravenous (iv) testing of pain sensibility with opioids (Morphine Test (MT)) is used to diversify an opioid sensitive versus a nonsensitive pain before starting a patient on opioid medication (1, 2, 3). So far, there is a lack of controlled trials which correlate the results of iv MT with the effectivity of an oral adjustment. In retrospective review of our own data only 72% of the patients responded to the oral adjustment in the same way as to the iv MT. Therefore, a randomised double-blinded trial has been started recently to investigate the sensibility and specitivity of the MT regarding pain sensibility to opioids and effectivity of the consecutive oral adjustment of opioid medication.

Material and Methods: After ethic committee approval, up to now 13 patients were randomised double-blinded to an iv morphine versus saline infusion at 2 different time intervals. Before, they had been documenting their pain intensity (VAS) and activity index (NAS) over 7 days. During time of infusion, pain intensity, respiration rate, width of pupils and side effects were noted every 15 minutes. All patients were then switched to an oral application of sustained released morphine at certain time intervals

Results: The infusion of saline did not lead to a significant reduction of pain in any patient 4 patients experienced a significant reduction of pain intensity ("responders") during the MT During consecutive oral adjustment with sustained released morphine 3 of 4 responders had again a decrease of pain. During investigation 9 patients showed no significant alteration in pain intensity at any time. Looking at the activity score, 2 responders had a marked increase. Some "non-responders" had a decrease of their activity index. In 1 responder medication had to be determined after developing edema of the thighs. All non-responders were discontinued for opioid medication. Typical side effects were observed more frequently in "non-responders" independently of route of administration

Conclusion: Preliminary results of the ongoing study demonstrate that all patients with a positive response to an iv MT also benefit from oral opioid application. Especially, no patient without pain reduction during the MT had a pain reduction during oral intake. This indicates that there is no false negative response for the iv MT

A.591 Long-term oral opioid therapy in patients with non-cancer pain

M. Strumpf, M. Zenz R. Dertwinkel, D. Rothstein. *University Departement of Anaesthesiology, Intensive Care Medicine and Pain Therapy, BG-Kliniken Bergmannsheil Bochum, Germany*

Background: There is considerable controversy about opioid therapy in patients with chronic non-cancer pain. The opponents argue that this therapy lacks of efficacy and leads to uncontrolled side effects Therefore we investigated all patients treated with opioids over a long period of time in our clinic.

Material and Methods: Data from 352 patients were evaluated retrospectively. 40 patients were treated ≥ 3 years. Pretreatment period, response to opioids, intensity of pain, measured by visual analogue scale (VAS), dosages of the opioids and side-effects were evaluated.

Results and Discussion: 15 males and 25 females were included. The duration of pretreatment lasted 10.6 years During the pretreatment period, patients had a total of 1242 regional blocks, 15 neurolytic blockades and 51 operations. The mean duration of opioid treatment was 4.9 years. 24 patients had pain relief of >50% (responder), 16 patients had a pain relief between 25–50% (partial responder) Pain decreased from VAS 8.6 before onset of treatment to VAS 3.9 during treatment. On the average, 273.7 mg slow release morphine/day (range: 30–990 mg) was used in 24 patients Buprenophine (n = 9) was used with a mean dosage of 2.61 mg/day (range: 0.6 to 4.6 mg), slow release DHC in 4 patients (average dosage: 307.5 mg/day, range: 120–720 mg) and slow release dextropropoxyphene in 3 patients (average dosage: 480 mg/day, range. 300–900 mg) Dosages were stable in 32 patients, increased in 3 and decreased in 3 patients. In 2 patients dosages were variable. Side-effects (sedation, vertigo, nausea, vomiting, pruritus) decreased, constipation increased during the long-term therapy.

Conclusion: If other therapies proved to be ineffective, controlled treatment of non-cancer pain with oral opioid analgesics may be a therapy with acceptable side effects and stable dosages

A.592 Electroacupuncuture for knee pain in elderly patients

G Broumas, N. Palgimesi, I Grigoropoulou, S. Papanastasiou, G Pavlidis, C. Taiganidou. *Pain Relief Unit and Anaesthetic Dept, Piraeus General Hospital, Greece*

Background and Goal of Study: Acupuncture is one of the oldest types of pain treatment and it is known that it increases endorphins in various parts of the CNS [1] Electroacupuncture has been shown to provide analgesia through production of endorphins at 4 and 100 Hz[2] and serotonin at 200 Hz The goal of this study was to investigate the potentials and the efficacy of a combined treatment of auricular acupuncture and electroacupuncture in two frequencies in elderly patients with knee pain who had taken anti-inflammatory drugs (NSAIDs) in the past.

Materials and Methods: 92 elderly patients (>65 years) of the Pain Relief Unit complaining about knee pain were studied. They had been either unsuccessfully treated or they had stopped taking NSAIDs because of gastric bleeding or renal deterioration 2 patients, previously operated for total knee replacement were excluded from the study The present analgesic technique included a) a semi permanent needle at the knee point of the ear, inserted at the first day of treatment b) 7 courses of electroacupuncture in both knees at the acupunctural points S 34–36 or GB 33–34 on the lateral and SP 10 or L 7–8 on the medial aspects of the knee. No other medication was used The patients were assessed immediately after the treatment and once a month afterwards a) by our Knee Pain Scale including assessment of physical functioning, quality of night sleep, knee flexion, ability to walk without walking stick, performance in family surrounding b) by the patient's satisfaction and acceptance of the technique The duration of the analgesic effect was also documented

Results and Discussion: 90 patients, 26 male and 64 female were studied. Immediately after the courses 72 patients (80%) were clearly improved and very satisfied. Surprisingly, 15 patients were not improved but very satisfied by the technique. 3 posttraumatic patients were slightly improved during the acute phase The duration of the analgesic effect varied from 1 (67%) to 7 months (8%) No complications were reported.

Conclusion: Electroacupuncture combined with auricular acupuncture seems to be safe and effective in most elderly patients and provide an excellent alternative to NSAIDs treatment.

A.593 Treatment of frozen shoulder with an interscalene block

P Lierz, P Hoffmann, P. Felleiter, K. Hoerauf. *Dept. of Anes. B, University of Vienna, 1090 Vienna, Austria*

After mobilisation of a frozen shoulder, patients should work with a physiotherapist one to two times a day. In the remaining time patients have to exercise on their own; otherwise, the shoulder will loose mobility again. Exercise is only possible when the patients are free of pain during the exercises. Therefore adequate analgesic therapy for four to five days after the first mobilisation is of great importance. We treated patients suffering from a painful frozen shoulder with interscalene blockade of the brachial plexus for mobilisation. We investigated the efficacy of this technique by the registration of additional analgetics use and asking the patient's assessment The observation time was 18 months.

Methods: 37 patients were treated with an interscalene blockade (Winnie) of the brachial plexus using a catheter inserted at the affected side. Catheter location was verified with electric nerve stimulation. In all patients a bolus of 20 ml bupivacaine 0.375% was given for the first mobilisation, followed by 10 ml bupivacaine 0.25% every 6 hours

Results: In 34 of 37 (92%) patients mobilisation of the shoulder could superfound without general anaesthesia. 33 of 37 (89%) patients did not need any additional analgesics during the following mobilisations. The mean duration of catheter treatment was 4 days; infections occurred The following side effects were observed at the first mobilisation Horner syndrome in 20 patients (54%); paresis of the recurrens nerve in 9 patients (24%); paresis of the phrenic nerve in 6 patients (16%). During the consecutive treatment a Horner syndrome was visible in 15 patients (41%) and a paresis of the recurrens nerve in 8 patients (21%) In an interview after the end of the treatment period all patients stated that they would choose this method again, if necessary.

Conclusions: With the use of this regional anaesthesia technique it was possible to provide comfortable pain therapy during the mobilisation period. For a sufficient analgesia with only a mild motor blockade of the motoneurons the exact location of the catheter tip is important, which can be verified using electrical stimulation.

A.594 Intra-articular morphine: a relevant analgesic after day-case arthroscopy?

P. Grattidge, M. Månsson. *Department of Anaesthesia, General Hospital, 572 28 Oskarshamn, Sweden*

Background and Goal of Study: Whilst intraarticular morphine (IAM) has been shown to have analgesic effect following arthroscopy (1), clinical benefit has not always been confirmed (2) This double-blind study aimed to determine whether a perioperative balanced analgesia regimen is enhanced by the addition of IAM

Materials and Methods: 100 day-case arthroscopy patients were randomised following anaesthesia (diclofenac/propofol/fentanyl/sevoflurane), to receive intraarticularly 20 ml 0 5% bupivacaine with or without 4 mg morphine (Gps: B + M and BUP) Patients assessed their pain by visual analogue scale (VAS 0 = no pain to max 10) at 2, 4, 6, 8, 12, 24, 48 h; recorded intake of rescue analgesic (paracetamol 500 mg + codein 30 mg) and occurrence of side-effects. Data was collected by telephone intervue on the 3rd day. VAS scores analysed by ANOVA, analgesic intake by Mann-Whitney U test.

Results and Discussion: Data was available from 95 patients, mean age 37 yrs range 16–68, 73% men, and 62% underwent interventional arthroscopy. Main results:

	Mean pain score (VAS 0–10)				Nil rescue analgesic % pat			Nausea % pat
	4 h	12 h	24 h	48 h	12 h	24 h	48 h	
BUP	2 1	2 7	1 7	1 6	43	43	40	9
B + M	2 0	2 0	1 8	1 4	39	36	36	39*

No significant differences except nausea * χ^2 P = 0 001

Median 3 tablets, range 1–11, were taken in both groups by those requiring rescue analgesic, intake was similar in the subsets gender and type of arthroscopy

Females had higher pain scores at all times and this was significant during the first 8 h (p = < 0.05). Interventional arthroscopy was associated with similar or lower pain scores compared to diagnostic (p = 0.05 at 6 &8 h) and a higher level of patient satisfaction, mean 9 vs 7 9, p = 0 01

Conclusion: In an arthroscopy population receiving balanced analgesia in the form of diclofenac, fentanyl and intraarticular bupivacaine, the addition of IAM did not result in superior or more long-lasting analgesia. This study also suggests that gender and case-mix are factors to be taken into account in pain perception measurement

A.595 Efficacy of bupivacaine infiltration upon postoperative pain after ambulatory shoulder arthroscopy under general anaesthesia

M. de Nadal, G Agreda, S Massenet[1], I. Salgado, A. Lacasta, P Cabré, V.A. Gancedo. [1]*Departments of Anesthesiology and Traumatology, Vall d'Hebron University Hospitals, Barcelona, Spain*

Background & Goal of the Study: Although intraarticular bupivacaine and/or morphine have demonstrated useful in some orthopedic procedures to lower postoperative pain (1, 2), the efficacy of local anesthetic infiltration in the subacromial space, which is not enclosed within a capsule (3), has not yet been proven The purpose of this study was to ascertain if bupivacaine infiltration after surgery would lower postoperative pain intensity and the request for analgesia in patients undergoing ambulatory shoulder arthroscopy under general anesthesia.

Material & Methods: Double blind, randomized, placebo-controlled prospective study in 40 patients. At the end of the surgery (subacromial decompression for subacromial impingement syndrome) and before closure of the portals, patients were injected with 30–40 ml of saline or 0.25% bupivacaine into the subacromial space Postoperative pain was measured using VAS (0–100 mm) at arrival in PACU, 30 minutes, 1, 2 hours and at hospital discharge Analgesic requirements of the patients in both groups were recorded Demographic data was compared using the t-test or rank sum test as appropriate Pain VAS scores and analgesic demands were analyzed by one-way ANOVA Results are expressed in mean ± SD

Results: Groups were similar with respect to age, weight duration of surgery and intraoperative dose of fentanyl. We found no differences on patients report of pain, time to first request for analgesic and total dose of postoperative analgesic, although mean VAS pain scores at 30 minutes were higher in the placebo group (5.9 ± 0.9) compared to the bupivacaine group (4 2 ± 2.6) (p = 0.08). No unplanned admissions and no significant differences in hospital stay were found between the two groups

Conclusions: The use of postoperatively bupivacaine infiltration into the subacromial space was not associated with reduced postoperative analgesia requirements and neither with a shorter hospital stay in ambulatory shoulder arthroscopy patients

A.596 Intrapleural bupivacaine for prevention of pain after nephrectomy

R. Greif[1], K. Reiter[1], M. Chwala[2], J Neumark[1]. [1] *Department of Anesthesiology and Critical Care Medicine, Donauspital, Vienna 1220,* [2] *Department of Urology, Donauspital, Vienna 1220, Austria*

Controversial results (due to different techniques, dosages and different types of operations) have been published concerning the efficacy of post operative pain relief after ip (intrapleural) installation of local anesthetics The purpose of this study was to investigate whether ip 20 ml Bupivacaine 0 25%, every 6 hours, after nephrectomy will significantly reduce the need of post operative systemic opioids.

Methods and Patients: After informed consent and approval by the local ethic committee, 40 patients for elective nephrectomy were randomised into 2 groups At the end of the operation an ip catheter was placed medioaxillary at the 6th intercostal space in 22 patients and 20 ml Bupivacaine 0.25% was injected every 6 hours for 2 days, while 18 patients served as control

We compared the total amount of Piritramide needed postoperatively for the first 48 hours, and the time that elapsed after the insertion of the ip catheter until the first request for a systemic analgesic.

Analysis of variance and t-test (modified for samples with different variances) were performed to compare the total doses of Piritramide. T-test and Wilcoxon signed rank test were performed to compare the time until the first analgesic was asked for.

Results: There was no significant difference between the two groups concerning age, gender, duration of operation, type and duration of anesthesia. The total amount of Piritramide in the ip catheter group was significantly lower ($p < 0\ 01$) than in the control group on both days (23 mg ± 3.3 SE vs 45 mg ± 5.8 SE on the first day and 9 mg ± 2.5 SE vs 23 ± 3.7 SE on the second day) The time when the first analgesic was asked for was longer in the study group vs the control group (mean 5 h vs 2 h, median 3 5 h vs 1 h), but statistically significant only with the t-test ($p < 0\ 03$), while borderline ($p = 0.0609$) with the less powerful, but parameter free Wilcoxon signed rank test

Conclusion: 20 ml Bupivacaine 0.25% intrapleurally every 6 hours for two days reduces the need for systemic opiates for about 50% and may double the painfree time after nephrectomy The question now remains whether reducing systemic analgesia is an advantage for the patient and enough to recommend an invasive technique of analgesia such as the intrapleural installation of local anesthetics

A.597 Intraperitoneal bupivacaine injection and infusion via subphrenic catheter for postoperative pain management in laparoscopic cholecystectomy

Umit Karadeniz, Ozcan Erdemil, Suheyla Unver, Hilal Ayoğlu,
Ferruh Ayoğu, Sevim Ebil. *Türkie Yüksek İhtisas Hospital/Ankara, Turkey*

Laparoscopic cholecystectomy is frequently associated with less postoperative pain as compared with open cholecystectomy and causes three types of pain (visceral, parietal and shoulder pain). Laparoscopic pain is usually treated with i m or i.v. analgesic drugs, although some authors have used epidural analgesia or local anesthetic via subphrenic catheter (1, 2) The purpose of this prospective study was to evaluate the effect and the type of local analgesia via a subphrenic catheter compared to systemic analgesia on post operative pain scores.

Sixty patients (ASA grades I and II) who were undergoing elective cholecystectomy were studied after approval by the ethics committee. Local anesthetics or placebo solutions were given via a subphrenic catheter as follows bolus injection immediately after the creation of pneumoperitoneum (S1). bolus injection at the end of the operation (S2) and were infused after the operation during postoperative period for four hours (S3). Patients were randomly divided into four groups: **Group I** (control) received 20 ml of % 0.9 saline during S1, S2, S3. **Group II** (pre-cholecystectomy) received 20 ml of % 0.5 Bupivacaine during S1 and 20 ml of 0.9% saline during S2, S3. **Group III** (post-cholecystectomy) received 20 ml of 0.9% saline during S1, S3 and received 20 ml. of % 0.5 Bupivacaine only during S2. **Group IV** (infusion) received 20 ml of % 0.9 saline during S1, S2 and 20 ml of % 0.5, Bupivacaine infusion during S3. The degree of postoperative pain was assessed using visual analog scala (VAS-for visceral pain) and verbal rating scale (VRS-for parietal pain) scores on arrival in the recovery room just after surgery (T0) and at 1/2 h (T1), 1 h (T2), 2 h (T3), 4 h (T4) postoperatively. Consumption of analgesic agents (i.v. or i.m. meperidine when VAS score >4), the presence of shoulder pain, nausea and vomiting were recorded

Although VAS pain scores were less in all groups, it was only significant at T0, T1, T3 and T4 in Group IV when compared to the control group. However, no significant difference was observed in VRS scores between the groups. The least analgesic requirement occurred also in Group IV.

In conclusion, bupivacain infusion via subphrenic catheter effectively reduced visceral pain and the consumption of adjuvant opioid analgesia. In addition to the effective pain control, absence of side effects, easy and risk-free application make the infusion of local anesthesia via subphrenic catheter, a method of choice for post-operative pain in laparoscopic cholecystectomy patients.

A.598 Randomized double-blind comparison of intravenous regional guanethidine with placebo in postoperative pain

E.W.S. Cheam, P P. Chen, R.M Calcroft. *Department of Anaesthesia and Intensive Care, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong, PRC*

Introduction: The sympathetic nervous system has a role in pain transmission and modulation (1). Intravenous regional sympathetic blockade with guanethidine has been widely used in chronic pain management. This study aimed to investigate the effect of intravenous regional guanethidine on post-operative pain

Methods: After local ethical committee approval and written informed consent, 37 ASA I–II patients undergoing removal of orthopaedic prostheses from limbs were studied General anaesthesia was induced using propofol 2–2 5 mgkg^{-1} and fentanyl 1 mcgkg^{-1}, and maintained with patients breathing spontaneously isoflurane 1–2 5% and nitrous oxide 70% in oxygen via a laryngeal mask airway Following inflation of a pneumatic tourniquet on the operated limb, patients were randomised in a double-blind fashion to either receive intravenous guanethidine (10 mg for upper limb and 20 mg for lower limb) or placebo. Upon deflation of the tourniquet at the end of surgery, non-invasive blood pressure and pulse rate were recorded every minute for five minutes. Verbal numeric score for pain were obtained at 15, 30 and 60 minutes, and at 2, 4, 6 and 24 hours after arrival in recovery room. The amount of post-operative analgesics requested and the time to first dose of analgesic were noted. Overall patient satisfaction with pain relief was assessed using a five-point scale. Statistical analysis was performed with Chi-square, Student-t or Mann-Whitney U test, with $p < 0.05$ being significant.

Results & Discussion: 22 and 15 patients received IVR guanethidine and placebo respectively. There was no difference in age, site of surgery and tourniquet time Post-tourniquet deflation mean blood pressure and pulse rate, verbal numeric scores and patient satisfaction were similar between the two groups. Overall, 59% of patients did not request for any supplementary analgesic compared with 40% in the placebo group ($p = 0.25$). The time to first request for rescue analgesic was similar in both groups

Conclusion: IVR guanethidine does not have any clinical advantage in acute pain relief after removal of orthopeadic implants, although the amount of postoperative analgesic consumption appeared to be lower

A.599 Clonidine does not affect postoperative pain when given as the sole analgesic agent into the axillary brachial plexus sheath

S Sia, A. Lepri, C. Pullano[1] *Department of Anesthesia, Centro Traumatologico Ortopedico, Firenze;* [1] *Ospedale "A Pugliese", Catanzaro, Italy*

Introduction: Clonidine (C) increased the duration of analgesia after axillary brachial plexus block when mixed with local anesthetic.[1] However the efficacy of C as sole analgesic has not been evaluated This study was conducted to determine if C has analgesic effects on its own when administered into brachial plexus sheath

Materials & Methods: 30 patients scheduled for hand surgery, were randomly divided into 3 groups of 10. Axillary brachial plexus block was performed with lidocaine and a catheter was inserted into the neurovascular sheath. At the end of surgery, considered as baseline, patients received through the catheter 15 ml of saline (group I), 150 μg of C in 15 ml of saline (group II) or 15 ml of 0.25% bupivacaine (group III). Postoperative pain on a visual analog scale (VAS) was checked every 2 hours until the end of the study period (6 hours). Ketorolac tromethamine 30 mg i.m was given on request Time from baseline to onset of pain and total dose of ketorolac were recorded. Side effects were also evaluated. Data were analysed using analysis of variance, Student-Newman-Keuls-, Kruskal-Wallis- and chi-squared test as required

Results: Demographics, type and duration of surgery were not significantly different between the groups There were no differences between group I and group II in time to onset of pain (72 ± 30 vs 68 ± 28 min), dose of ketorolac (45 ± 15 vs 42 ± 15 mg) and VAS scores during the study period Bupivacaine produced a significant prolongation of postoperative pain free period (260 ± 84 min; P < 0.001 vs groups I and II) and a reduction in total dose of ketorolac (42 ± 15 mg; P < 0.001 vs groups I and II) VAS scores were lower in group III than in the other groups at 2 (P < 0.001) and 4 (P < 0.05) hours. Two patients in group II had clinically relevant hypotension and one bradycardia

Conclusions: Although several "in vitro" lines of evidence[2, 3] support an intrinsic analgesic effect of C, we conclude that administration of 150 μg of C into the axillary brachial plexus sheath at the end of surgery does not produce postoperative analgesia

A.600 Postoperative analgesia after ankle block: lidocaine plus clonidine. A dose-ranging study

S. Sia, M Bartoli, A. Lepri, O. Marchini, C. Rivituso. *Department of Anaesthesia and Intensive Care, Centro Traumatologico Ortopedico, Firenze, Italy*

Background & Goal of Study: Addition of clonidine (C) to local anaesthetics prolonged pain relief after nerve block[1]. The aim of this study was to define a dose-response relationship for C added to lidocaine for ankle block.

Materials & Methods: 80 patients undergoing foot surgery were randomized to receive ankle block with 15 ml of plain 1 5% lidocaine (Group I; n = 20), 1.5% lidocaine with 37.5 μg C (Group II, n = 20), 1.5% lidocaine with 75 μg C (Group III; n = 20) or 1.5% lidocaine with 150 μg C (Group IV, n = 20). Time from the performance of the block to onset of postoperative pain and to first pain medication request were recorded. Ketorolac tromethamine 30 mg i.m. were given on request. Level of pain was evaluated on visual analog scale (VAS) 3, 6 and 9 hours after the block Total amount of ketorolac required during the study period (9 h) was recorded Side effects were also evaluated. Analisys of variance, Student-Newman-Keuls-, Kruskal-Wallis and Mann-Whitney U test were used as appropriate. Data are expressed as mean ± DS.

For statistical significance see text

	Group I	Group II	Group III	Group IV
Onset of pain (min)	162 ± 47	236 ± 49	274 ± 57	345 ± 50
Time to first analgesic	201 ± 54	279 ± 51	327 ± 66	395 ± 52
Dose of ketorolac (mg)	52 ± 16	40 ± 17	39 ± 17	34 ± 14
VAS 3 h	3 ± 1 9	1 1 ± 1 2	0 5 ± 0 7	0 2 ± 0 3
VAS 6 h	4 2 ± 1 1	3 7 ± 1 6	3 3 ± 1 5	1 9 ± 1.2
VAS 9 h	3 3 ± 1 0	3 1 ± 1.0	2 8 ± 1.0	2.5 ± 1 1

Results: (see table 1) time to report of first pain and to first analgesic request were significantly different between all groups (II vs III· P < 0.05; P < 0.001 in the remaining cases). There was a significant difference with regard to the dose of ketorolac (I vs IV· P < 0 001, I vs II and III: P < 0.05) and the VAS score at 3 h (I vs II, III and IV: p < 0.001, II vs IV P < 0.01), 6 h (IV vs I and II: P < 0.001; IV vs III: P < 0.005) and 9 h (I vs IV: P < 0.05). No clinically relevant side effects were recorded.

Conclusions: addition of C prolongs the duration of analgesia after ankle block. Unlike other similar studies[2], our results argue for a dose-dependent effect. An increased dose was not accompanied by a greater number of adverse side effects

A.601 Postoperative analgesia by continuous epidural infusion of bupivacaine after repairing herniated lumbar disk

J. Hernández-Palazón, J A Tortosa, C García-Palenciano,
J M. García-Cayuela, M.V. Cañadillas, M.J Del Vas. *Service of Anaesthesia, University Hospital "Virgen de la Arrixaca", Murcia, Spain*

Background and Goals of Study: The objective of this study was to determine the efficiency of the use of low bupivacaine doses in continuous epidural infusion for pain treatment, in the first 24 hours of the postoperative period, after lumbar laminectomy.

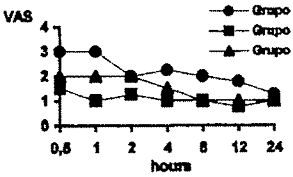
Materials & Methods: A randomized double-blind study was carried out on 27 patients, undergoing elective lumbar discectomy The patients were allocated to one of the following groups Group 1 (n = 8), 0 0625% bupivacaine infusion at 1.5 mg.h^{-1}; Group 2 (n = 10), 0.125% bupivacaine infusion at 3 mg h^{-1}, Group 3 (n = 9), 0 250% bupivacaine infusion at 6 mg.h^{-1}. Before the closure of the surgical incision, the surgeon placed, under direct vision, a catheter in the epidural space in the middle of the surgical field In the moment of the closure of the skin, a bolus of 4 ml of the anaesthetic solution was administrated through the epidural catheter, followed by an infusion of the same solution at 2 4 ml h^{-1}. The supplementary analgesia was provided by a system of ketorolac PCA at 10 mg per demand dose, with a lock-out interval of 5 min and a maximum dose of 30 mg in 4 h In those cases of VAS superior to 3 and maximum ketorolac dose, we used, as rescue analgesic, an IV bolus of meperidine (20 mg). The ketorolac doses during the period of study were registered The VAS, VRS, and side effects were evaluated. The VRS recorded during 24-h period was summed to yield the total pain relief (TOTPAR) score Statistical analysis included Kuskal-Wallis, Mann-Whitney and Friedman test

Results: The three groups were similar respect to age, gender, body size, amount of fentanyl used intraoperatively, and duration of surgery. No patient developed infection at the catheter site. The consumption of analgesics and TOTPAR score are reflected in following table

	Group 1	Group 2	Group 3
Ketarolac (mg)			
Total (24 h)	120 (80–180)*	30 (0–50)	30 (20–60)
0–8 h	60 (60–60)*	20 (0–40)	30 (10–40)
8–16 h	30 (0–60)*	5 (0–20)	0 (0 –20)
16–24 h	30 (20–60)*	0 (0–10)	0 (0–10)
Meperidine i v (mg)	20 (0–60)*	0 (0–0)	0 (0–0)
TOTPAR	17 5 (12–19)*	20 5 (17–21)	19 (15–21)

Values are median (range) * Significantly different from Groups 2 and 3 ($P < 0$ 05)

The postoperative pain scores were lower in Groups 2 and 3 as compared to Group 1 (figure)



Conclusions: We conclude that the continuous epidural infusion of 0 125% or 0 250% bupivacaine is an easy and effective technique in the management of pain after lumbar laminectomy. However, we observe a greater incidence of adverse effects (numbness, need for urinary catheterization) in those patients treated with 0.250% bupivacaine

A.602 Continuous epidural analgesia with morphine and ketamine for postoperative pain relief

N. Andonov, J Hristova, V. Teneva, T Spirovska, M. Micevski *Clinic of Anaesthesiology and Intensive Therapy, Clinical Center, Skopje, Republic of Macedonia*

Background & Goal of Study: The epidural administration of opioids provides effective analgesia with side effects of nausea, vomiting, pruritus and sedation. Ketamine, an N-methyl-D-aspartic acid receptor antagonist, has been shown to produce postoperative pain relief administrated epidurally (1, 2) The goal of this study was to compare the analgesic and side effects of continous epidural analgesia with morphine alone and morphine plus ketamine during the first 24 h after elective lower abdominal surgery

Material & Methods: Forty-six ASA 1–2 patients were randomly assigned into two equal groups. Group I received a bolus of 3 mg epidural morphine in 10 ml saline before the end of surgery, followed by a continous infusion at a rate of 0 1–0 3 mg/h Group II received a bolus of 3 mg morphine and 10 mg ketamine in 10 ml saline administered epidurally, followed by continous infusion of morphine at a rate of 0.14–0.28 mg/h and ketamine at a rate of 0.4–0.8 mg/h All patients were observed for pain relief and adverse effects for 24 h. Pain was assessed using linear analogue scale from 0–10.

Results & Discussion: Mean morphine consumption was 9.5 ± 0.4 mg for Group I and 6.8 ± 0 2 mg for Group II. Pain relief was better in Group II than in Group I ($p < 0.05$), despite Group II utilized significantly less morphine ($p < 0.05$) Vomiting occurred more frequently in Group I (30%) than in Group II (14%) The frequency and severity of pruritus and sedative levels were similar in the two groups

Conclusion: Continous epidural analgesia with morphine plus ketamine decreases morphine consumption, provides better pain relief and less adverse effects than continous epidural analgesia with morphine alone. So, this method is an acceptable alternative to continous epidural analgesia with morphine alone after low abdominal surgery

A.603 Caudal clonidine for postoperative analgesia in adults

A.C. Van Elstraete[1], F. Pastureau[1], T Lebrun[1], H Mehdaoui[2].
[1] Département d' Anesthésie, CMC Saint Paul and [2] Département d'Anesthésie-Réanimation, Centre Hospitalier Universitaire, Fort-de-France, Martinique, France

Background and Goal of Study: Caudal block can be used in adults for sacro-perineal surgery (1). This prospective, double-blind, randomized, placebo controlled study was designed to assess the efficacy of caudally administered clonidine in adults when added to local anesthetics

Materials and Methods: After IRB approval, 58 ASA I–II patients scheduled to undergo haemorrhoidectomy were included in the study. Patients were randomly allocated to one of two groups. All received a caudal injection of a mixture containing 0.5% isobaric bupivacaine 35 mg in 2% lignocaine 140 mg with epinephrine 1/200000; In addition, patients were given clonidine 75 μg (group C) or saline 1 ml (group S). Postoperative followup was performed by a blinded observer. Duration of analgesia defined as the time from the caudal injection to the first request for supplemental analgesics was recorded For patients not requiring analgesics during 48 hr, duration of analgesia was defined as 2880 min

Analysis of variance (ANOVA) was used for Intergroup comparison and Fisher's Exact Test for categorical data. Results are expressed as mean ± SD Statistical significance was considered at $P < 0.05$.

Results and Discussion: Demographic data were comparable between groups. Bradycardia was significantly more frequent in the group C compared to the group S ($p = 0.01$) but without significant changes in Mean Arterial Pressure No significant differences were found between groups for other side effects The median time to first analgesic request was significantly longer in group C (729 ± 120 min) than in group S (276 ± 131 min) ($P = 0.01$).

The main side effects of extradurally administered clonidine are hypotension, bradycardia and sedation (2) Hypotension was not marked in our study. Bradycardia was more frequent in the clonidine group but had no hemodynamic repercussion. Clonidine produces dose-dependent sedation (3) Postoperative sedation in our study was similar in both groups This could be explained by the low dose of clonidine used

Conclusion: Clonidine may be a potentially useful drug when prolonged postoperative analgesia is required after caudal block in adults.

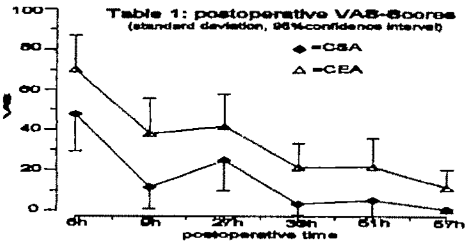
A.604 Continuous spinal anaesthesia or continuous epidural anaesthesia for postoperative pain control after hip replacement?

S. Cord, M. Mollmann *Abt. für Anasthesie und operative Intensivmedizin, St Franziskus-Hospital Munster, D-48145 Munster, Germany*

Background & Goal of Study: Both continuous spinal anaesthesia (CSA) and continuous epidural anaesthesia (CEA) are supposed to provide adequate postoperative pain relief. The purpose of this randomized, prospective study was to compare quality of analgesia, occurrence of side effects and patients' satisfaction between spinal and epidural administration of bupivacaine 0.25% during the first postoperative 72 hours.

Materials & Methods: Following approval of the Ethics Committee, 102 patients scheduled for hip replacement (65 f, 37 m) were randomly assigned to one of 2 groups: Group 1 ($n = 51$) received CSA for intraoperative and postoperative management, Group 2 ($n = 51$) received CEA. Right after surgery, the CSA-Group received a 1 ml bolus (bv 0.25%), followed by continuous Infusion of 10 ml/24 h. The CEA-Group received a 10 ml bolus, followed by 2 ml/h. The level of pain was gauged from verbal rating scale (VRS) 6 hours after the first bolus in the Intensive Care Unit and from visual analogue scale (VAS) twice a day, the degree of motor blockade was registered with Bromage score. For statistical analysis, Wilcoxon two sample test and Chi-square test were used.



Results & Discussion: No difference in demographics was noted 90.2% of the CSA-Group, but only 21.6% of the CEA-Group reported complete analgesia on the VRS The VAS-scores given by the CSA-Group were significantly lower than those of the CEA-Group (figure)

The percentage of patients with a motor block decreased within the first 24 hours from 39.2% to 5.88% in the CSA-Group and from 9.8% to 0% in the CEA-Group The satisfaction was considered excellent in 92.2% of the CSA-Group and in 70.6% of the CEA-Group During the first 24 hours, nausea and vomiting occurred significantly more often in the CEA-Group No neurological impairment arose

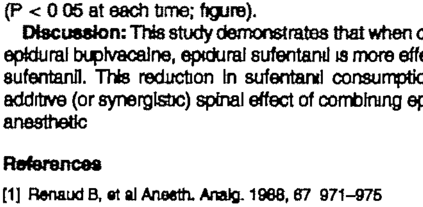
Conclusion: CSA and CEA are effective and safe for postoperative pain relief after hip replacement Compared to CEA, CSA provides faster onset of pain relief, ensures better analgesia and results in more satisfied patients

A.605 Comparison of epidural and intravenous sufentanil patient-controlled analgesia combined with epidural bupivacaine

E Jacob, J. Jons, J.F Deleuse, M Lamy. *Department of Anesthesia and ICM CHU Liège, Domaine du Sart Tilman, B-4000 Liège, Belgium*

Introduction: The risk of respiratory depression may be less with epidural lipophilic opioid than with epidural morphine [1] However, controversy over the mechanism(s) of action of epidural sufentanil (spinal vs systemic action) persists [2, 3] All previous studies compared epidural to intravenous sufentanil alone. Clinical practice usually involves use of local anaesthetics and opioid, to benefit from a possible additive or synergistic effect of their combination. We therefore compared epidural and intravenous sufentanil combined with epidural bupivacaine (BUPI) to relieve postoperative pain after major abdominal surgery.

Methods: After IRB approval, 40 ASA II–III patients were included in this randomized study Patients had surgery with general anaesthesia (isoflurane) and thoracic (T8–T11) epidural anaesthesia (6–8 ml) of BUPI 0.5% followed by a continuous infusion (6–8 ml/h) of BUPI 0.25%. On arrival in the PACU, patients were randomly allocated to receive a continuous infusion (5 ml/h) of BUPI 0.1% and epidural sufentanil (EPISUF) or the same epidural infusion of BUPI combined with intravenous sufentanil (IVSUF). Sufentanil in the two groups was administered using the same PCA pump and the same settings: bolus = 2.5 μg, lockout interval = 10 min. An investigator blinded to patient allocation group recorded the following parameters 4 h after the end of surgery, at 9.00, 14.00 and 19:00 on days 1 and 2: pain (100 mm VAS) at rest, during mobilization, and coughing, and the dermatomal extension of epidural analgesia Sufentanil consumption was also recorded every 4 h. Data (mean ± SEM) were analyzed by ANOVA.



Results: Patients characteristics were similar in the 2 groups. Pain relief at rest, during mobilization and coughing as well as extension of epidural analgesia were not significantly different in the two groups. Sufentanil consumption was 50% less in the EPISUF group than in the IVSUF group ($P < 0.05$ at each time; figure).

Discussion: This study demonstrates that when combined with low dose epidural bupivacaine, epidural sufentanil is more effective than intravenous sufentanil. This reduction in sufentanil consumption may result from an additive (or synergistic) spinal effect of combining epidural opioid with local anesthetic

A.606 Propofol *vs* naloxone: effect and adverse effect on epidural morphine-induced pruritus

Chung-Hyun Park, In-Young Chung[1], Soo-Young Kim[2]. *Dept. of Anesthesiology, Pochon CHA University, Medical College, Pochon, [1] Maria clinic, Seoul; [2] Dept of Family Medicine, Hallym University, Medical College, Seoul, Korea*

Background & Goal of Study: Pruritus is the most frequent undesirable symptom associated with epidural morphine. It is unpleasant and often difficult to treat. Naloxone is presently the drug of first choice for treating this symptom. However naloxone decrease the pain threshold in some cases. Recently it was reported that subhypnotic doses of propofol were efficient in relieving epidural-morphine induced pruritus (EMIP)[1]. In a prospective, randomized, double-blinded clinical trial, we compared the efficacy of propofol and naloxone for the treatment.

Materials & Methods: After obtaining informed consents from patients and with IRB approval, 92 patients having cesarean section, received epidural morphine 3 mg bolus, and 4 mg/day with continuous infusion for 2 days via Baxter infusor®. The patients who have pruritus with scratching were allocated to received either 20 mg propofol or 1.5 μg/kg naloxone intravenously. Pruritus and the level of postoperative pain were assessed 5 minutes later using 5 points pruritus rating scale (PRS) and 10 points visual analogue pain scale. Statistical analysis was performed using chi-square test and paired t-test. $P < 0.05$ was considered significant.

Results & Discussion: Sixty patients showed pruritus with scratching ($PRS \geq 3$). The overall success rate in treating pruritus was similar in two groups (propofol 73% vs naloxone 70%). Twenty-seven percent of the patients in the naloxone group had an increase in the level of postoperative pain versus none in the propofol group ($p = 0.018$). The beneficial effect of treatment was longer than 60 minutes in both groups.

	Propofol (n = 30)	Naloxone (n = 30)
Success rate	22 (73%)	21 (70%)
Change of VAS > 2	0 (0%)	8 (27%)*
Duration of effect (min)	176.9 ± 144.6	144.2 ± 152.5

Values are mean ± SD. *$p < 0.05$, VAS: 10 points visual analogue pain scale

Conclusion: These results suggest that 20 mg propofol and 1.5 μg/kg naloxone are equally effective in treating EMIP. However, the level of postoperative pain is significantly less in the propofol group than naloxone group.

A.607 What is the minimum effective dose of propofol in relieving epidural-morphine induced pruritus?

Chung-Hyun Park, Won-Sun Park, In-Young Chung[1], Soo-Young Kim[2]
Dept. of Anesthesiology, Pochon CHA University, Medical College, Pochon, [1]Maria clinic, Seoul; [2]Dept. of Family Medicine, Hallym University, Medical College, Seoul, Korea

Background & Goal of Study: Pruritus due to spinal morphine has been thought a facilitatory action of morphine on nonnociceptive neurons in the posterior horn. Mu-receptor antagonists are considered effective for the treatment of epidural-morphine induced pruritus (EMIP)[1]. However, they have been associated in certain cases with concomitant reduction in analgesia. It is noteworthy that propofol has been shown to produce marked spinal depression, in particular of the dorsal and ventral horn. Recently it was reported that subhypnotic doses of propofol were efficient in relieving EMIP. This study was designed to investigate an effective minimal dose of propofol.

Materials & Methods: After obtaining informed consents from patients and with IRB approval, 155 patients having cesarean section, received epidural morphine 3 mg bolus, and 4 mg/day with continuous infusion for 2 days via Baxter infusor®. The patients who have pruritus with scratching were allocated randomly to one of the three groups. Patients received 10 mg propofol intravenously in group I ($n = 25$), 20 mg in group II ($n = 25$) and 30 mg in group III ($n = 25$). Pruritus and the level of sedation were assessed 5 minutes later using 5 points pruritus rating scale (PRS) and 4 points sedation rating scale (SRS). Statistical analysis was performed using chi-square test, one-way ANOVA and paired t-test. $P < 0.05$ was considered significant.

Results & Discussion: Seventy-five patients showed pruritus with scratching ($PRS \geq 3$). The success rate was significantly greater in the group II (76%) and group III (80%) than in the group I (48%) ($p < 0.05$). Seven patients had an increase in sedation in the group III versus none in the group I and group II ($p < 0.05$). The beneficial effect of treatment was longer than 60 minutes in 100% of patients in group I, II and III.

Propofol	10 mg	20 mg	30 mg
Success rate	48%	76%*	80%*
Sedation rate	0%	0%	28%**
Duration of effect (min)	226.8 ± 162.7	222.4 ± 105.7	235.8 ± 141.2

Values are mean ± SD. *$p < 0.05$ versus 10 mg propofol group, **$p < 0.05$ versus 10 mg and 20 mg propofol proup

Conclusion: These results suggest that 20 mg propofol and 30 mg propofol intravenously are equally effective in treating EMIP than 10 mg propofol. However the level of sedation is significantly less in 20 mg propofol group than 30 mg propofol group.

A.608 Incisional morphine has no analgesic effect after inguinal herniotomy

Charlotte Rosenstock, Henrik Rasmussen, Gertrud Andersen, Claus Lund. *Department of anaesthesia, Herlev University Hospital, University of Copenhagen, Denmark*

Background and Goal of Study: Opioids induce antinociceptive effects after peripheral administration in experimental and clinical studies (1–2). The results of the clinical studies are conflicting (2–3). The objective of this study was to examine the possible effect of incisionally administered morphine on postoperative pain in patients undergoing inguinal herniotomy under general anaesthesia.

Materials and Methods: A total of 46 consecutive outpatients were included in a double-blind randomized, placebo-controlled study. At conclusion of herniotomy morphine was injected incisionally in 11 patients, intravenously in 10, and subcutaneously in 13. The placebo group of 12 had saline injected in the incision. Postoperative pain at rest and during mobilization was assessed with a visual analogue scale. Assessments were made immediately before and after herniotomy, at 2, 4, and 6 hours after surgery, and on the second and seventh postoperative day. Postoperative morphine and acetaminophen consumptions were recorded within the same period.

Results and Discussion: There were no significant differences in visual analogue scores between the groups at any time during the study. Overall differences in postoperative acetaminophen and morphine consumptions were insignificant.

Most studies finding an analgesic effect after peripheral administration of morphine have included patients undergoing arthroscopic knee surgery (2). Inguinal herniotomy is probably a more extensive surgical trauma compared with arthroscopy of the knee and, therefore, may cause more postoperative inflammation and more pain. The morphine dose in this study may have been too small as compared to the intensity of inflammation.

It is not known at what time after incision opioid receptors appear at the nerve endings. If none or very few opioid binding sites are present peroperatively, it is unlikely that incisionally administered morphine can produce an early pain relieving effect. Moreover the likelihood that any morphine is left to interact with newly produced opioid receptors in the wound several days after injection is probably very small.

Conclusions: The analgesic effect of a single 5 mg dose of morphine injected in a herniotomy wound is not superior to saline or to morphine given subcutaneously or intravenously.

A.609 Morphine titration in PACU. Comparison of two time intervals between bolus: 10 *vs* 5 min.

F. Aubrun, O Langeron, K. Quaisser, B Riou, P. Coriat. *Pitié-Salpêtrière, Paris, France*

Background: The goal of morphine titration is to rapidly relieve pain in acute care. Using this concept for postoperative pain management, we have implemented a continuous quality assurance program in the post anaesthesia care unit (PACU). According to analgesic efficacy and side effects, we have compared the interval between two morphine bolus: 10 min and 5 min.

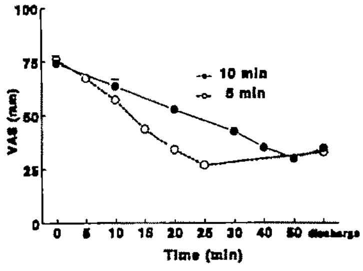
Patients and Methods: The patients were queried about the presence of pain and asked the rate pain intensity on a 100 mm visual analog scale (VAS). In the first period (400 patients), when pain increased to more than 30 mm, (VAS control) iv morphine was titrated up to 15 mg *every 10 min* by 3 mg increments (10 mg by 2 mg increments if weight < 60 kg). In the second period (400 patients), iv morphine was titrated *every 5 min*. A VAS reduction to less than 30 mm or major side effects (sedation, respiratory rate <10/min) lead to stop the morphine titration. Values are mean ± SEM.

Results and Discussion: There were no significant differences in analgesic scores and side effects at the end of titration (VAS 1) or on discharge (VAS 2) of the PACU, between the two groups (table 1). Sedation was

	Group 10 min	Group 5 min
VAS control mm	74 ± 4	76 ± 1
VAS (1) mm	30 ± 1	27 ± 2
VAS (2) mm	34 ± 1	33 ± 1
Side effects n (%)	40 (10)	28 (7)
Sedation n (%)	106 (27)	144 (36)*

* $p < 0.01$ vs 10 min

however more pronounced in group 5 min. The mean dose of morphine was 9 6 mg and was not influenced by the interval between bolus. Pain was more rapidly relieved in the group 5 min (figure 1)



Conclusion: The major finding of this study was the most rapid analgesic effectiveness of morphine bolus injected every 5 min without significant increase in side effects incidence

A.610 Analgesia and respiratory depression time course during morphine loading dose in recovery room

L. Yakhou, C Jayr, V Therry, M.C. Savoyen, C. Ducret, V. Billard. *Institut Gustave Roussy, Villejuif, France*

Background: After major surgery, a loading dose of intravenous morphine given in a recovery room is a useful starter to postoperative analgesia. The criteria of administration and duration of patients monitoring in recovery room are still debated. The goal of this study was to assess the time course analgesia and respiratory side effects during and after this loading dose.

Methods: Pain was assessed every 10–15 minutes using a simplified verbal score, SVS (from 0 = no pain to 5 = intolerable pain). The loading dose of morphine was given as follows: a bolus of 5 mg intravenously, then 3 mg every 10 minutes until the SVS was under 2 (2 = moderate pain) with no maximal dose.

Respiratory side effects were detected by $SpO_2 < 93\%$ or respiratory rate < 8/min.

Results are expressed as mean (min, max). Comparison were performed by t paired test Differences yielding $p < 0.05$ was considered significant

Results: Over a 3 months period, 27 consecutive patients were included. The total loading dose of morphine was 24 mg (8; 47). The simplified verbal score was 2 (2; 4) at the end of loading dose. In 5 patients loading dose was stopped before the criteria because of respiratory depression After loading dose, analgesia continued to improve, achieving a minimal simplified verbal score of 1 ($p < 0.05$), after an average delay of 40 min (10; 100)

Respiratory depression occurred in 13 patients (in 5 patients before the end of morphine loading dose, in 3 patients following the last bolus at 10 min and 60 min and in 5 patients the loading dose was stopped because of low respiratory rate).

Discussion: After intravenous morphine loading dose the maximal effects may be delayed regarding analgesia as regarding respiratory side effects. This suggests that the criteria for stopping morphine loading dose should be moderate pain rather than light or no pain and could be enraced by non opioid analgesics. Prolonged monitoring in recovery room (>1 hour after the last bolus) is always necessary.

A.611 Effects of morphine and oxycodone on respiration and haemodynamics

L Mildh[1], M. Scheinin[2], O. Kirvelä[3]. [1]*Dept. of Anaesthesiology, Helsinki University Hospital,* [2]*Dept. of Pharmacology and Clinical Pharmacology, Turku University;* [3]*Dept. of Anaesthesiology, Turku University Hospital, Finland*

Background: Thorough understanding of the respiratory and haemodynamic effects of morphine and oxycodone is necessary for their optimal use. These effects were studied on healthy volunteers under experimental pain stimulation.

Methods: 8 healthy male volunteers were studied in a random, double-blind and cross-over fashion. Pain was induced with a 300 mmHg tourniquet. After 4 minutes the subjects were given either morphine 0.14 mg/kg (M1), morphine 0.07 mg/kg (M2), oxycodone 0 14 mg/kg (O) or placebo (P) as a 2 minutes injection. The tourniquet was kept on for a total of 10 minutes (4 minutes post drug injection). Radial artery was cannulated for measurements of heart rate (HR), mean arterial pressure (MAP) and for sampling of blood gases (PaO_2 and $PaCO_2$), catecholamines and histamine. Oxygen saturation (SPO_2) was measured with a pulseoximeter. Respiratory inductive plethysmograph was used to measure minute ventilation (VE). Measurements of oxygen consumption (VO_2) and carbon dioxide production (VCO_2) were performed with a indirect calorimetry. Alveolar ventilation (VA) was calculated from formula $VA = 0.115 \times VCO_2/PCO_2$. Data sampling was done at baseline (bl), during pain stimulation (ps), right after drug injection (0), 4 minutes after drug injection (before releasing the tourniquet) (4) and 10, 15, 20 and 30 minutes after drug injection. ANOVA was used for data analysis and $p < 0\ 05$ was considered significant.

Results: P had no effect on measured parameters. Both M1 and M2 induced an immediate, but transient increase in MAP and HR ($p < 0\ 05$). No such effect was seen after O treatment Compared to P, all active drugs decreased VE ($p < 0\ 05$), with no difference between O, M1 or M2. However, VA decreased significantly more after O than after either of the M doses. This was also reflected in $PaCO_2$-values, which were significantly higher after O than after either M1 or M2. PaO_2 was lower than P only after O ($p < 0\ 05$). The changes in respiratory parameters were clinically insignificant, and quite similar after both M1 and M2

Conclusions: The difference in respiratory effects between oxycodone and both morphine doses is best explained by dosage; the potency ratio of 1:1 between oxycodone and morphine probably underestimates the potency of oxycodone However, the dosage cannot explain the difference in haemodynamic response, as cardiovascular stimulation was evident and similar for both morphine doses.

A.612 Control of immediate postoperative pain in patients who received remifentanil during balanced anaesthesia for moderately painful surgery

F. Servin[1], J.M. Desmonts[1], C. Conseiller[2], N. Clyti[3], M Hédouin[3]. [1]*CHU Bichat, Paris;* [2]*CHU Cochin, Paris;* [3]*Laboratoire GlaxoWellcome, Issy les Moulineaux, France*

Background: Remifentanil is a new μ-opioid agonist with an ultra-rapid elimination which implies an anticipation of postoperative pain by an analgesic treatment administered before remifentanil infusion is ended The objective of this prospective, double-blind, randomised study was to evaluate the efficacy and safety of propacetamol 2 g (P) associated with ketoprofene 100 mg (K) or nalbuphine 20 mg (N) in managing early postoperative pain.

Methods: 235 patients aged 18 to 65 years old, ASA status I–II, requiring a laparoscopic surgery (cholecystectomy, gynaecological surgery) with a planned duration of 45 min to 2 hours and receiving remifentanil during balanced anaesthesia were included into the study. They were randomized to receive, 30 minutes before the end of remifentanil infusion, either P and K or P and N (after the end of remifentanil infusion). Postoperative pain was evaluated during the first 15 minutes by behavioural score (BS graded from 1 to 3), and until discharge from recovery room by a simple verbal scale (SVS graded from 0 to 3). In case of postoperative pain, an analgesic rescue medication was administered to the patient

Results:

Group	PK (n = 120)	PN (n = 115)	p
Time to first rescue analgesic.			
median	37.5 min	32 min	NS
For the first 15 min after the end of remifentanil infusion			
BS < 2 (% patients)	80	74	NS
15 to 30 minutes after the end of remifentanil infusion·			
SVS < 2 (% patients)	56	50	NS
Administration of rescue analgesic 1 hour after the end of remifentanil infusion·			
(% patients)	47	46	NS

No serious adverse events have been reported in this study

Conclusion: In moderately painful surgery, the 2 combinations (propacetamol-ketoprofene or propacetamol-nalbuphine) in this study have a similar efficacy and were well tolerated. These 2 combinations provide a satisfactory analgesia during the immediate post operative period which allows a transition to other analgesia under the best conditions.

A.613 Control of immediate postoperative pain in patients who received remifentanil during balanced anaesthesia for severely painful surgery

M Chauvin[1], C. Lejus[2], P. Scherpereel[3], L Cheli-Muller[4], M. Hédouin[4]. [1]*CHU A Paré, Boulogne;* [2]*CHU Hôtel-Dieu, Nantes;* [3]*Hôpital C. Huriez, Lille;* [4]*Laboratoire GlaxoWellcome, Issy les Moulineaux, France*

Background: Remifentanil is a potent and selective μ-opioid agonist with an ultra-rapid elimination which implies an anticipation of postoperative pain by an analgesic treatment administered before remifentanil infusion is ended. The objective of this study was to evaluate the efficacy and safety of 2 dosages of iv morphine in managing immediate postoperative pain.

Methods: Adult patients, ASA status I–III, requiring a major abdominal or uro-genital surgery under laparotomy and receiving remifentanil during balanced anaesthesia were included into the study. They were randomized to receive iv morphine either 0.15 mg/kg or 0 25 mg/kg administered 30 minutes before the end of remifentanil infusion.

Postoperative pain was evaluated during the first 15 minutes by behavioural score (BS 1 to 3 graded), and until discharge of recovery room by a simple verbal scale (SVS 0 to 3 graded). In case of postoperative pain, a titration of morphine was performed until pain relief.

Results: 245 patients received the randomized study treatment. For the first 15 min after the end of remifentanil infusion:

Group.	0 15 mg/kg n = 121	0 25 mg/kg n= 124	p*
BS < 2 (% patients)	65	79	0.026

Between 15 and 30 min after the end of remifentanil infusion:

Group	0 15 mg/kg	0.25 mg/kg	p*
SVS < 2 (% patients)	30	41	0 030

*p level of significance <0 05

The percentage of adverse events was similar in the 2 groups; nevertheless, in the postoperative period, three respiratory depressions, two of which were late, occurred in the 0.25 mg/kg morphine group, with complete resolution for all three.

Conclusion: Although a number of patients experienced moderate or severe postoperative pain during the first 15 minutes after the end of remifentanil infusion, the majority of patients reported no noticeable pain during this period. The higher dose of morphine provided better pain control but cannot be recommended because of the respiratory depressions. Complementary studies should investigate optimising postoperative pain control following the use of remifentanil in severely painful surgery.

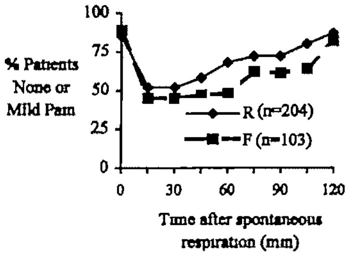
A.614 Morphine before the termination of remifentanil provides effective transition to routine analgesia after major surgery: a comparison with current practice

J.R. Sneyd. *On Behalf of the UK Remifentanil Study Group; Derriford Hospital, Plymouth, UK*

Background and Goal of Study: Remifentanil (R) is a potent μ-opioid agonist with a rapid onset and offset of action Measures should therefore be taken to prevent postoperative pain before R is discontinued. We compared postoperative pain control and recovery profiles when morphine (M) is given before the termination of R with routine pain management following fentanyl (F).

Materials and Methods: 316 male and female, ASA status I–III, patients (aged 18–75 years) scheduled for major abdominal, breast, gynaecological or orthopaedic surgery ($\geq$ 60 min duration) were recruited into this open study. 307 patients were included in the efficacy analysis. Patients were randomised 2:1 to receive either R (1.0 μg/kg then 0.5 μg/kg/min–0.25 μg/kg/min) or F (3.0 μg/kg then 1 5–3 μg/kg as required) Anaesthesia was induced with propofol and maintained with isoflurane (0.8% and 0 6% end tidal with F and R respectively). Thirty minutes before the anticipated end of surgery R patients received M (0 2 mg/kg) Postoperative pain was managed in both groups with M: 2.5–5.0 mg bolus doses as required followed by patient controlled analgesia (PCA) when pain control was considered satisfactory. Pain scores (none, mild, moderate, severe) and sedation scores (awake, drowsy, very drowsy, unrousable) were recorded every 15 minutes until discharge to the ward.

Results and Discussion: Intraoperatively R patients had fewer interventions. R patients were more likely to have no or mild pain 30–120 min after spontaneous respiration (Fig) (odds ratio >1). Over 50% of R patients required no additional M prior to PCA.



F patients received the last bolus dose 100 ± 43 min before the cessation of isoflurane. Therefore mean times to spontaneous and adequate respiration, and extubation were all significantly ($p < 0.05$) shorter in F patients (3.9 ± 3.7 vs 6 7 ± 3 8 min; 5.6 ± 5.1 vs 8.0 ± 4.3 min; 8 2 ± 6.0 vs 8 8 ± 4.6 min). These differences are clinically unimportant. R patients were more likely to be classified as 'awake' 0–45 minutes after spontaneous respiration (odds ratio >1).

Conclusion: In the transition to routine analgesia, M (0 2 mg/kg) given 30 minutes before the termination of R does not compromise recovery and provides a similar level of pain control to that provided by current practice following F.

A.615 Postoperative pain management and recovery after remifentanil-based anaesthesia with isoflurane or propofol for major abdominal surgery

E Kochs[1], D. Cote[2], L. Deruyck[3], V. Rauhala[4], M Puig[5], E Polati[6], J Verbist[7], B. Upadhyaya[8], C. Haigh[8] [1]*TU Munchen, Germany*, [2]*Hôpital Laval, Canada;* [3]*AZ Sint Lucas,* [7]*Glaxo Wellcome, Belgium,* [4]*Keski-Suomi Central Hospital, Finland;* [5]*Hospital del Mar, Spain,* [6]*Universita di Verona, Italy;* [8]*Glaxo Wellcome R&D, UK*

Background and Goals of Study: Remifentanil (R) is a potent μ-opioid receptor agonist that is rapidly metabolised by nonspecific esterases Hence, R's analgesic effects dissipate rapidly upon termination of its infusion. This means that post-operative pain may occur earlier in recovery[1, 2] This study investigated whether morphine (M) or fentanyl (F) given prior to cessation of R-based inhaled anaesthesia with isoflurane (I) or TIVA with propofol (P) would provide immediate post-operative pain control without compromising recovery

Materials and Methods: Following ethics approval and signed consent, 558 patients, >18 years, ASA class I–III undergoing major abdominal surgery were included in 42 centres across 14 countries Patients were randomised to anaesthesia with R + I or R + P. Induction was with R (1 μg/kg), P (0.5 mg/kg) and an infusion of R at 0 5 μg/kg/min. Following tracheal intubation R infusion was reduced by 50%. I was commenced at 0.6% end-tidal and for TIVA group, P was started at 100 μg/kg/min. Anaesthesia was maintained by titrations of R & I or R & P Twenty-five minutes before the end of surgery, either F (0 15 mg) or M (15 mg) was given as a randomised, double-blind dose. A second dose of F (0 05 mg) or M (7 mg) was given post-operatively when moderate or severe pain occurred Subsequent analgesia in recovery room (RR) and upon discharge was provided at the investigator's discretion

Results and Discussion (all times as median, min)

Endpoints	I		P	
	M (N = 142)	F (N = 135)	M (N = 138)	F (N = 136)
Time to. – Spontaneous respiration	6 0	8 0	8 0	8 0
– Extubation	9 0	10 0	11 0	11 0
– Aldrete score >9	11 5	12 5	15 0	14 0
None/mild pain at Aldrete >9 (%)	49	48	48	42
% patients given 2nd opioid dose	91	98	89	93
Time to 2nd opioid dose (min)	21 0	21 0	24 0	26 5
RR Discharge eligibility (min)	87 0	91 5	97 0	103 0

R with I or P provided good anaesthesia. Administration of F or M before termination of R gave good pain control in the immediate post-operative period and did not delay recovery. Proportions of patients reporting severe pain at Aldrete >9 were: 28% (F) and 21% (M) receiving R + I and, 26% (F) and 21% (M) receiving R + P The most common adverse events were post-operative nausea (45–48%), vomiting (9–12%) and shivering (6%); which occurred with equal frequency across both R + I and R + P groups.

Conclusions: For major abdominal surgery, F or M administered ca. 25 mins prior to discontinuing R-based anaesthesia provides effective transitional analgesia in the immediate post-operative period without affecting the rapid recovery seen with R or eligibility for RR discharge. Further studies should be designed eg utilising NSAIDs and opioid combinations to further optimise transitional analgesia

Supported in part by a grant from Glaxo Wellcome

A.616 Opioid-sparing effect of tenoxicam in the management of postoperative pain. Influence of different dosage regimens

V. Dimitriou, G.S Voyagis, A. Malefaki, C Pratsas, A. Douma, G. Tsiganos. *Departments of Anaesthesia, G. Gennimatas and Sotiria Hospitals, Athens, Greece*

Background: The use of non-steroidal anti-inflammatory drugs (NSAID's) either alone or in combination with opioids, appear to be increasing in the management of postoperative pain (1, 2) In a double-blind randomized study we investigated the efficacy of tenoxicam, an intravenous (i v.) injectable NSAID, in the management of postoperative pain, when used in two different doses (20 mg and 40 mg), in patients undergoing major orthopaedic surgery

Materials and Methods: In the study were included 72 patients, ASA I–II, well matched for characteristics, scheduled for total hip arthroplasty under spinal anaesthesia. They were randomly allocated in three groups to receive 60 min before surgery either 20 mg i v tenoxicam (group A, n = 24), or 40 mg i.v. tenoxicam (group B, n = 23), or 2 ml of saline (group C, n = 25) In the postoperative period all patients had the possibility of intramuscular pethidine administration (1 mg/kg) on demand. Postoperative pain scores assessed on a visual analog scale (VAS, 0–10) and opioid requirements were recorded at 3, 6, 12, 18, 24 h after motor and sensory restoration.

Results: Our results are summarized in the table. Both tenoxicam groups had lower pethidine consumption (A: 167 ± 47 mg, B: 156 ± 39 mg) when compared to control group (278 ± 47 mg), Bonferroni p-value < 0.0001

VAS	Group A	Group B	Group C	ANOVA P-value
3 h	2.4 ± 0.3	1.9 ± 0.4$^{\blacktriangle}$	3.9 ± 0.5*	<0.0001
6 h	2.9 ± 0.5	2.3 ± 0.4$^{\blacktriangle}$	4.3 ± 0.5*	<0.0001
12 h	3.3 ± 0.5	2.9 ± 0.4^{+}	4.7 ± 0.6*	<0.0001
18 h	3.7 ± 0.5	3.4 ± 0.5	5.0 ± 0.7*	<0.0001
24 h	4.3 ± 0.6	4.0 ± 0.5	5.4 ± 0.7*	<0.0001

Multiple paired comparisons between groups with Bonferroni p-value: *C vs A and B, $p < 0.0001$, $^{\blacktriangle}$B vs A, $p < 0.001$, $^{+}$B vs A, $p = 0.05$.

Conclusion: Both tenoxicam dosage regimens are effective in the management of postoperative pain as they reduce significantly the postoperative mean pethidine consumption. However the dose of 40 mg seems to offer better quality of pain relief than the dose of 20 mg in the immediate postoperative period of 12 h.

A.617 Oral naloxone in opioid-associated constipation: an intra-individual controlled study

W. Meissner, U. Schmidt, M. Hartmann, B. Dohm, K. Reinhart *Clinic of Anesth. and Intensive Care and Hospital Pharmacy, F.-Schiller-University, 07740 Jena, Germany*

Background: Opioid-related constipation is one of the most frequent side effects of chronic pain treatment. Enteral administration of naloxone while blocking opioid action at the intestinal receptor level has low systemic bioavailability due to marked hepatic first-pass metabolism. Clinical experience in treating opioid-induced constipation with enteral naloxone is limited to case reports (1). The aim of this study was examine the effects of oral naloxone on opioid-associated constipation in an intraindividually controlled manner.

Material and Methods: After IRB approval chronic cancer pain patients with oral opioid treatment and constipation were enrolled in this study. Constipation was defined as lack of laxation and/or laxative therapy in at least three out of six days. Laxation and laxative use were monitored for the first six days without intervention ("pre-nalox" period). Then, oral naloxone was started and titrated individually between 3 × 3 to 3 × 12 mg/d depending on laxation and withdrawal symptoms. After the four-day titration period, patients were observed for further six days ("nalox" period). The Wilcoxon Signed Rank Test was used to compare number of days with laxation and laxative therapy in the two study periods.

Results and Discussion: Of the 20 patients studied, four patients did not reach the "nalox" period due to death, operation (due to underlying malignancy), systemic opioid withdrawal symptoms, or therapy-resistent vomiting. Of the 16 patients who completed the study, 15 were treated with morphine with a median dose of 239 mg/d during the pre-nalox and 252 mg/d during the nalox period (p = ns). One patient was treated with buprenorphine. The mean naloxone dose in the "naloxone" period was 18.9 mg/d. In the 6 day "nalox" compared to the "pre-nalox" period, the number of days with laxation increased from 2.1 to 3.6 ($p < 0.01$) and the number of days with laxative medication decreased from 6 to 3.4 ($p < 0.01$). Mild withdrawal symptoms such as restlessness, sweating, and nausea were observed in 9 patients with daily doses of 3 × 6 mg naloxone. Moderate side effects were observed in 2 patients following accidental single dose administration of 36 mg naloxone resulting in yawning, sweating, shivering, and increase of pain. Some of the patients reported mild or moderate abdominal propulsions and/or abdominal cramps shortly after naloxone administration. All side effects terminated after 0.5 to 6 hours.

Conclusion: This first controlled study demonstrates that orally administered naloxone improves symptoms of opioid associated constipation and reduces laxative use. To prevent systemic withdrawal signs, therapy should be started with low doses and patients carefully monitored during titration.

A.618 Comparison of morphine and tramadol in patient-controlled analgesia after microvascular breast reconstruction

Marja Silvasti, Nils Svartling, Mikko Pitkänen. *Department of Anaesthesia, Töölö Hospital, Helsinki University Central Hospital, Finland*

Background: Tramadol is a weak opioid analgesic, which efficacy has not yet been compared with morphine in patient controlled analgesia (1). Therefore, we studied the dose requirements and side effects of morphine and tramadol administered by patient controlled analgesia (PCA).

Materials and Methods: After approval by the Ethics Committee, 54 consenting ASA I–II women undergoing breast reconstruction used PCA (Graseby 3300) for postoperative pain for 42 hours. All patients had isoflurane-nitrous oxide anaesthesia and received fentanyl 3 μgkg^{-1} at the induction followed by fentanyl 1–2 μgkg^{-1}h^{-1}. In the recovery room patients were randomised to receive in a double-blind fashion either i.v. 1 mg morphine or i.v. 10 mg tramadol increments given every 2 min by the anaesthetist (loading) until they were painfree. PCA was then commenced. The bolus dose was morphine 45 μgkg^{-1} or tramadol 450 μgkg^{-1} with the maximum of six times an hour. The drug solution contained either morphine 2 mgml^{-1} or tramadol 20 mgml^{-1} in a blinded fashion. The lockout period of the PCA pump was 5 min. Patients were assessed for pain (VAS) and side effects before and after the loading and at 3, 6, 18, 30 and 42 h.

Results and Discussion: Both groups had similar demographics. In the recovery room mean morphine and tramadol consumption was 10 mg and 137 mg (ratio 1:14) and on the ward altogether 59 mg and 628 mg (ratio 1:11). 11 patients in the tramadol group and one patient in the morphine group had nausea during loading ($p < 0.001$, Mann-Whitney U). There was no difference in the quality of analgesia (VAS) or incidence of side effects, such as nausea, vomiting, pruritus and sedation between the groups after loading in the recovery room and on the ward.

Conclusions: Morphine: tramadol efficacy ratio varied from 1:11 to 1:14 in this study. In these both groups the pain relief was similar. Tramadol caused more nausea during loading.

A.619 Tramadol infusion *vs* morphine PCA for post-Caesarean section pain: a pilot study

Anton van den Berg[1], Tom Mphanza, Roswitha Al Ahmed,
Mamdouh Bassioni, Jackie Ragheb, Iftikhar Ali *Anaesthesia Depts.,*
[1] King Khaled Eye Specialist Hospital and Riyadh Military Hospital, Riyadh, Saudi Arabia

Introduction: Tramadol, a non-addictive opioid, induces scant respiratory depression and less sedation than pethidine and morphine; given with PCA following laparotomy, tramadol 640 mg 24 hr^{-1} provides equivalent analgesia to pethidine 604 mg 24 hr^{-1} [1, 2]. This data suggests its suitability for addition to postoperative IV fluids to provide analgesia. We compared the efficacy and side effects of tramadol infusion (tramadol) with morphine PCA (morphine) until 48 hours after Pfannenstiel laparotomy.

Method: With Ethical Committee approval and patient consent 40 patients randomly received tramadol 1.5 mg kg^{-1} or morphine 0.15 mg.kg^{-1} as analgesic adjunct to anaesthesia, followed by infusion of tramadol (150 mgs in 500 mls dextrose saline; 30 ml.kg^{-1}. 24 hrs^{-1}) or morphine PCA (1.5 mg demand, 6 min lockout), respectively. Postoperatively, patients were assessed hourly by nurses, daily by Pain Service doctors and, independently, by AvdB, for pain, sedation, satisfaction, nausea, vomiting, headache, dizziness, drowsiness, pruritis, mobility, sweating, heart rate, blood pressure, respiratory rate, rescue analgesia/antiemesis, urinary retention, backache, and nurses comment using standard objective and subjective protocols. Analysis used Fishers Exact, Chi-squared, Mann Whitney U and Students 't' tests. ($p < 0.05$ significance).

Results: Groups (N = 20 each) were comparable. Mean opioid consumption per each 24 hr. period were tramadol 834 mgs and 741 mgs (total 1576 mgs in 48 hrs); morphine 64 mgs, 41 mgs (total 105 mgs in 48 hrs). Observers and patients rated pain relief, patient satisfaction, and all parameters similarly, except that morphine induced more dizziness ($p < 0.006$), drowsiness ($p < 0.0040$) and pruritis ($p < 0.0150$).

Discussion: Use of conventional opioids for postoperative analgesia is open to abuse by staff and patients. PCA is costly (pump and disposables), and prone to discontinuation through technical problems.

Conclusion: Addition of tramadol to routine postoperative IV fluids is a simple, efficacious and cost effective alternative to morphine PCA, with advantages of inducing less dizziness, drowsiness and pruritis.

A.620 Patient-controlled analgesia with pethidine after elective gastrectomy: epidural *vs* intravenous routes

P.P. Chen, E.W.S. Cheam, M. Ma, V Y S. Hung, K K Lam, W.D. Ngan Kee, T. Gin *Dept of Anaesthesia & Intensive Care, The Chinese Univ. of Hong Kong, Prince of Wales Hospital, Hong Kong, SAR, PRC*

Background: Patient-controlled epidural pethidine has been reported to produce high quality postoperative analgesia after caesarean section. (1) This randomised controlled study aimed to compare the effectiveness of patient-controlled epidural with intravenous pethidine after major abdominal surgery.

Method: After local ethical committee approval and informed consent, ASA I–III patients scheduled for elective gastrectomy were recruited. A standardised general anaesthetic technique supplemented by thoracic epidural anaesthesia was employed. After reversal of anaesthesia, the patients were randomised in a double-blind manner to either receive PCA pethidine through the epidural or intravenous route A bolus dose of pethidine 25 mg was first administered when the visual analogue score (VAS) for pain >40 mm (time zero) Ten minutes later, PCA was started with a 10 mg bolus and 10 min lockout VAS for pain, a 4-point sedation score and cumulative pethidine consumption was recorded at 1 h, 4 h, 8 h, 24 h and 48 h The presence and severity of nausea, vomiting and pruritus were recorded for the periods 0–8 h, 8–24 h and 24–48 h. The overall patient satisfaction was recorded using the VAS. Blood samples for assay of serum pethidine and norpethidine were taken at 0 h, 4 h, 8 h, 24 h and 48 h Statistical analysis was performed with Chi-square, Student-t or Mann-Whitney U test, $p < 0.05$ being significant.

Results & Discussion: 30 patients have completed the study There was no difference in age, sex, ASA status, VAS for pain at rest and coughing, sedation score, incidence of side effects and length of hospital stay between the two groups. Pethidine consumption and serum pethidine levels were lower in the epidural group up to 24 h ($p < 0.05$) There was no difference in norpethidine levels Overall patient satisfaction was similar.

Conclusion: Although epidural PCA pethidine achieved lower pethidine consumption and serum pethidine levels, it did not appear to be clinically important when compared to the intravenous route.

A.621 Addition of adrenaline to pethidine for patient-controlled epidural analgesia

W D. Ngan Kee, K.S. Khaw. *Chinese University of Hong Kong, Hong Kong, China*

Background and Goal of Study: Addition of adrenaline was found previously to increase the duration of analgesia and reduce systemic absorption from a single dose of epidural pethidine after Caesarean section.[1] This study aimed to investigate the addition of adrenaline to pethidine for patient-controlled epidural analgesia (PCEA).

Materials and Methods: Ethics Committee approval and informed consent were obtained In a randomized, double-blind study, we assigned 80 patients having elective Caesarean section to receive postoperative analgesia in the first 24 h by patient-controlled epidural analgesia (PCEA) using pethidine 5 $mg.ml^{-1}$ with (Group Pa) or without (Group Po) adrenaline 5 $\mu g.ml^{-1}$. The PCEA settings (bolus 25 mg, lockout interval 10 min, 4-h maximum dose 150 mg) were identical. Pain at rest and on coughing, nausea, pruritus and sedation were measured by visual analogue scale at 2 h, 6 h and 24 h. Drug consumption and patient satisfaction were recorded Data were analysed using Student's t-test, the Mann-Whitney U test and Fisher's exact test $P < 0.05$ was considered significant.

Results and Discussion: Seventy-eight patients completed the study Patient characteristics, pain scores (Fig 1) and satisfaction were similar between groups. There was a trend towards lower mean 24 h consumption of pethidine in Group Pa (231.5; SD 140.5 mg) vs Group Po (289 5; SD 139.5 mg, $P = 0.07$). Patients in group Pa had greater nausea at 2 h and 24 h and greater pruritus at 2 h.

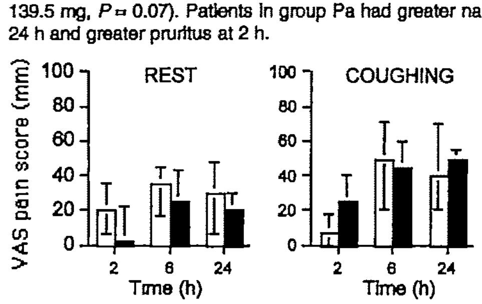

Fig 1 VAS pain scores (median, interquartile range) □ = Group Pa ($n = 40$), ■ = Group Pa ($n = 38$)

Conclusion: Addition of adrenaline to pethidine for PCEA does not have significant clinical advantages

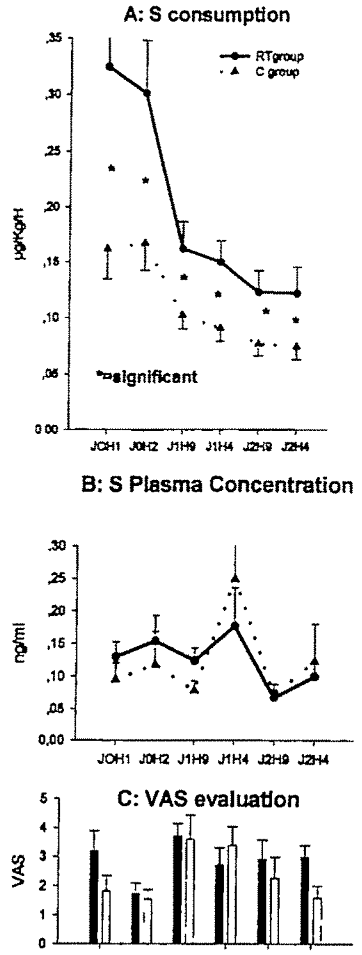
A.622 Safety of sufentanil postoperative patient-controlled analgesia after renal transplantation

P Gourdange, P Lavand'homme, M Carlier, J P Squifflet, R Verbeeck, L Van Obbergh. *Anesthesiology, Renal Transplantation, and Pharmacokinetics Depts , UCL Medical School, University of Louvain, 1200 Brussels, Belgium*

Postoperative pain relief in kidney transplanted patients remains a problem i.e. morphine is not safe as active metabolites accumulate (1). The safety of S analgesic during RT (2) and in patients with chronic renal failure (3) has been studied, so was S PCA for postoperative analgesia in normal patients (4) We assessed the efficiency and safety of S PCA for postoperative pain relief after RT

Methods: After informed consent and institutional approval, 22 patients (aged 21 to 65 years) were studied: 11 undergoing RT were compared with 11 control patients (C) undergoing abdominal surgery After general anesthesia with S atracurium and isoflurane, a PCA pump (Abbott Life Care) was connected for intravenous S analgesia during 48 hours, as follows background infusion 2.5 μg/h, bolus 5 μg, lock out time 5 min and maximum dose 80 μg/4 h Plasma S concentrations (ng/ml) are assessed by radioimmunoassay (4), PCA consumption (μa/kg/hour), quality of analgesia (Visual Analogue Scale-VAS 0 to 10) and side effects were recorded at 1 (J0H1) and 2 (J0H2) hours after extubation and twice daily at 9 am and 4 pm during the first (J1H9, J1H4) and the second (J2H9, J2H4) postoperative days Comparison was assessed by Student t Test, $p < 0.05$ was significant. Results are presented as mean ± SEM



A: S consumption

B: S Plasma Concentration

C: VAS evaluation

Results: S consumption was significantly more important in RT group than in C group (fig. A), however plasma S (fig B) concentrations were similar as well as the VAS (fig. C). Side effects such as sedation and nausea-vomiting were rare and their incidence equal in the two groups

Conclusion: This study shows that S PCA can safely be used after

RT Although S consumption was higher in the RT group, plasmatic concentrations were similar. Satisfactory VAS were obtained in both groups.

A.623 Why patients feel positive about patient-controlled analgesia

G M. Chumbley, P. Salmon, G M Hall. *St George's Hospital Medical School, London and Department of Clinical Psychology, University of Liverpool, UK*

Background and Goal of Study: Previous studies have shown that patients report greater satisfaction with patient controlled analgesia (PCA), than with conventional intramuscular analgesia [1]. Satisfaction with PCA was not accompanied by an increase in the amount of analgesia used or low pain scores [1]. Superficial questions about satisfaction are problematic, as they tend to produce positive results [2] The goal of this study was to examine why patients respond positively to PCA and discover what variables influence satisfaction.

Materials and Methods: 200 patients completed a questionnaire about their experiences of PCA, 24 to 72 hours after PCA had been withdrawn. The questionnaire covered the following topics: strategies for using PCA, pain relief, side-effects, safety, advantages and disadvantages of PCA, worries associated with its use and control over pain. The Chi-squared test was used to compare responses between groups. $P < 0.05$ was considered significant.

Results and Discussion: Patients who were 'extremely positive' about PCA ($n = 83$), were compared with those who were not ($n = 117$). Patients who were 'extremely positive' reported significantly better pain relief, had better control over their pain, found that their machine worked well, they could use their machine whenever they liked, felt safer using PCA and were less likely to feel peculiar in the head. These patients were less worried about overdosing themselves or the machine giving them too much drug There were no differences in the strategies that they employed to control their pain or other side-effects. Although the 'extremely positive' patients achieved control over their pain, more of the significant answers centred around safety

Conclusion: Patient satisfaction is a complex issue in which issues of safety play the dominant role.

A.624 Postoperative pain after low-dose intrathecal morphine in elective laparoscopic cholecystectomy

C. Motamed, H. Bouaziz, D. Franco[1], D. Benhamou. *Service d'Anesthésie; [1]service de Chirurgie, Hôpital Antoine-Béclère, 92141 Clamart, France*

Background: Postoperative pain after laparoscopic cholecystectomy can be important especially in the early postoperative hours[1]. The aim of this study was to assess the effects of a low-dose of intrathecal morphine injected prior to elective laparoscopic cholecystectomy on pain scores, postoperative analgesic requirements and side-effects.

Methods: After ethical approval and informed consent had been obtained, 32 adults ASA I–II (aged 20–70), were randomised into two groups: spinal, "S" and control, "C". The S group had an intrathecal injection of 100 or 75 μg of morphine (75 for those aged $\geq$ 65 years), before general anaesthesia The C group had a subcutaneous injection of a saline solution in the L3–L4 interspace. For all patients, iv morphine PCA was used as rescue analgesia. Postoperative morphine requirements after 20 h, pain scores at rest and while coughing, sedation, time to first food intake, nausea and vomiting, urinary retention, quality of sleep, time to discharge, and satisfaction were assessed by an observer blinded to the study. For statistical analysis we used Student's *t* test, Mann Whitney rank sum test, chi-square test and ANOVA for repeated measures as appropriate.

	Postoperative hours				*P* *S vs C
	2	4	6	20	
Spinal (n = 15)					
Morphine (mg) mean ± SEM	3 2 ± 2	5 3 ± 2	6 5 ± 3	10 ± 5	
Pain (VAS, mm) rest mean ± SD	18 ± 12	18 ± 17	11 ± 12	8 ± 12	
Cough mean ± SD	35 ± 17	30 ± 15	24 ± 19	20 ± 12	
Control (n = 17)					
Morphine (mg) mean ± SEM	6 7 ± 3	10 ± 2	13 ± 3	20 ± 6	p = 0.04*
Pain (VAS, mm) rest. mean ± SD	37 ± 20	29 ± 21	26 ± 19	20 ± 12	p = 0 001*
Cough mean ± SD	56 ± 20	57 ± 20	48 ± 24	40 ± 20	p = 0 001*

Results: No significant difference was noticed with regard to patients characteristics, anaesthetic requirements, nausea and vomiting, sedation, quality of sleep and time to discharge. Morphine requirements and pain scores were significantly lower in the S group (table). The incidence of urinary complications requiring treatment was significantly higher in the S group (27% vs 6%, $p = 0.01$).

Conclusions: Under the conditions of our study, low dose intrathecal morphine provides effective analgesia in laparoscopic cholecystectomy, at the expense of an increased incidence of urinary complications.

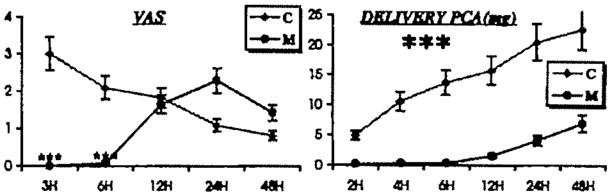
A.625 Effect of intrathecal low-dose morphine for postoperative analgesia after total hip replacement

J.M. Mendieta, J I Fernandez-Liesa, G Marco, A. Macías, R Calderón, F. Carrascosa, J.L. Arroyo. *Department of Anesthesia, Clínica Universitaria de Navarra, Spain*

Background and Goal of Study: A significant increase in the use of intrathecal opioids for postoperative analgesia has been observed in the last few years[1, 2, 3]. Our purpose in this study was to evaluate the quality and duration of postoperative analgesia using low dose intrathecal morphine and estimate its safety and concomitant adverse effects.

Methods: After ethical approval and informed patient consent was obtained, 25 patients (ASA 1–2) aged 62 to 80 years and weighting 44 to 115 Kg, undergoing total hip replacement under spinal anaesthesia using hyperbaric bupivacaine 0.5% were randomized to receive either saline (C group) or 0.1 mg morphine (M group) in a double-blind manner. Postoperative analgesia was provided using intravenous morphine by a Patient Controlled Analgesia device. Pain was assessed using VAS and morphine consumption during the first 48 h postoperatively Results were analysed by χ^2 test and student t-tests, $p < 0.05$ was considered significant.

Results: VAS was significantly reduced in the M group during the first 12 hours compared with the C group (fig.1). Morphine consumption was significantly higher in the C group compared with the M group throughout the postoperative period (fig.2). There were no difference in the incidence of postoperative nausea and vomiting and pruritus between both groups. Urinary retention was significantly higher in the M group.



Conclusion: The use of intrathecal morphine (0.1 mg) provides better postoperative analgesia than Bupivacaine alone and reduces analgesic requirements with no increase in adverse effects except urinary retention.

A.626 Comparison of intrathecal morphine sulphate and morphine hydrochloride as analgesics for hip arthroplasty

H Winkelbauer, V. Grabner, M. Kreuzer, I. Schindler. *Division of Anaesthesia and Intensive Care Medicine Orthopedic Hospital Gersthof, Vienna, Austria*

Background & Goal of Study: Intrathecal (I.t.) morphine produces analgesia in the postoperative setting (1) The aim of our study was to compare I t. morphine sulfate (MS) and i.t. morphine hydrochloride (MHCl) for postoperative analgesia with respect to duration of analgesia as well as side effects.

Materials & Methods: The retrospective analysis included 103 consecutive patients after total hip arthroplasty. In all patients spinal anaesthesia (L1–5) was performed with plain 0.5% bupivacaine 3.5–4 ml together with 0.1 mg MS in 52 patients and 0.1 mg MHCl in the following 51 patients. Duration of analgesia was defined as time between I.t. drug administration and first postoperative analgesic treatment. Nausea, emesis, pruritus, sedation, and respiratory depression were evaluated. Data are given as median values and ranges, Mann-Whitney-Wilcoxon and the Fisher's exact test were used Significance was assumed at the 5% level of probability

Results and Discussion: There were no significant differences in physical characteristics between MS and MHCl treated patients. In patients who received MS the median value for first postoperative analgesic treatment was 540 min (180–1440) vs. 390 min (180–1440) in patients treated with MHCl Significantly more patients were completely pain-free within the first 6 hours after i t MS ($p < 0.05$) After 24 hours 13 out of 52 MS treated patients were still pain-free vs 4 out of 51 patients ($p < 0\ 05$) The frequency and type of side effects were similar for both groups There was a tendency for fewer demands for postoperative analgesic treatment in patients who received i t MS.

Conclusion: MS, given intrathecally, provided excellent analgesia after total hip arthroplasty. An explanation for the longer duration of analgesia of i t MS might be the higher pH-value compared to MHCl

A.627 Efficacy of intrathecal neostigmine for the relief of postinguinal herniorrhaphy pain

Ping-Heng Tan, Kang Liu, Martin S. Mok[1] *Dept of Anesthesiology, Veterans General Hospital, Kaohsiung, Taiwan, ROC; [1] University of Southern California, Los Angeles, CA 90033, USA*

Background and Goal of Study: Recently intrathecal administration of neostigmine at varid doses has been reported to produce analgesia without neurotoxicity in animal studies and human volunteers with experimental pain The present study was undertaken to evaluate the efficacy and safety of intrathecal neostigmine in the relief of pain in patients after inguinal herniorrhaphy surgery.

Materials and Methods: After giving their consents 60 men scheduled for elective inguinal herniorrhaphy with spinal anesthesia were randomly enrolled into 3 groups· Group I ($n = 20$) received intrathecal (IT) tetracaine 15 mg, group II ($n = 20$) received IT tetracaine 15 mg + neostigmine 50 μg, and Group III ($n = 20$) received tetracaine 15 mg + neostigmine 100 μg Onset of anesthesia, duration of analgesia, vital signs, and incidence of adverse effects were recorded for 24 hours post drug. Data were expressed in mean ± SEM A value of $p \leq 0.05$ was regarded as statistically significant difference.

Results and Discussion: The demographic data were similar for the three groups. Onset of anesthesia (time to T6 sensory block) was significantly faster in Group III (1 6 ± 0 7 min) and Group II (2 3 ± 0.9 min.) compared to Group I (5 5 ± 1.9 min) Motor block (time to lift leg) was greatly prolonged in Group III with a average of 6 4 hr compared to 4 hr. in Group I Group III also showed a later onset of post surgical pain ($\bar{x} = 523$ min) than Group I ($\bar{x} = 243$ min.) There was a significantly higher incidence of adverse effects associated with IT neostigmine, especially nausea and vomiting, 15% in Group I, 40% in Group II, and 50% in Group III

Conclusion: Our study showed that intrathecal neostigmine at 50 μg or 100 μg enhanced the onset of tetracaine anesthesia and provided analgesia lasting about 6–9 hours. However, there are increased incidences of prolong motor blockade and nausea or vomiting

A.628 A new N-type calcium channel blocker SNX-111 administered intrathecally for acute postoperative pain

P.G Atanassoff, M W B Hartmannsgruber, M Sturaitis, A. Otellin
Department of Anesthesiology, Yale University School of Medicine, New Haven CT, USA

Introduction: Voltage-dependent calcium channel conductance is essential for the nervous system to signal a painful event Intrathecal administration of calcium channel blockers of the L-type to induce antinociception proved to be ineffective (1). The present investigation was designed to evaluate two different dosages of the new N (neuronal)-type calcium channel blocker SNX-111 administered intrathecally in patients with acute postoperative pain

Methods: After IRB approval, 15 patients participated in this multicenter, randomized, phase II, double-blind pilot study to assess the safety and effectiveness of SNX-111 after total hip replacement The patients were provided with an intrathecal catheter for postoperative pain management They received 2–3 ml of bupivacaine 0.5% with epinephrine (5 μg/ml) for intraoperative anesthesia. Immediately prior to surgery, a continuous infusion of either placebo ($n = 6$), 0 7 μg/hr ($n = 6$) or 7 μg/hr ($n = 3$) of SNX-111 was started and continued throughout the operative procedure as well as for 48 h into the postoperative period Routine pain assessments were performed every 4 h by means of a *visual analog scale* (VAS) ranging from 0 = no pain to 100 = worst imaginable pain Assessments were started 4 h after surgery and continued for 48 h postoperatively Systemic morphine consumption administered by patient-controlled analgesia (PCA) was recorded during the study period. Data are expressed as mean ± SD. Statistical comparisons were made between the placebo and the low dose groups using ANOVA and unpaired t-test, $p < 0\ 05$ was considered statistically significant.

Results: The three patient groups were comparable with respect to age, weight, and height. No statistical difference was found between the placebo group and those patients receiving SNX 0 7 μg/hr with regard to pain scores and morphine consumption All three patients receiving 7 0 μg/h and one patient with 0.7 μg/h of the study drug had to be discontinued after 24 h due to adverse events such as dizziness, blurred vision, and sedation. VAS scores and morphine consumption within the first 48 hours after surgery are displayed in the Table

Discussion: The existence of three distinct types of calcium channels (L, T, and N-type) in sensory neurons are reported in the literature (2) While the administration of L-type calcium channel blockers such as verapamil, diltiazem, and nicardipine without additional morphine proved ineffective (1), intrathecal administration of SNX-111 (N-type) appears to have an antinociceptive effect useful for perioperative pain relief. The higher dose of 7.0 μg/h, however, was associated with too many adverse events in this investigation to be recommended for routine clinical use The optimal dose of SNX-111 useful for clinical practice may lie between the two doses studied.

	VAS8	VAS16	VAS24	VAS48	MOR24	MOR48
Placebo	38 ± 38	20 ± 22	32 ± 31	10 ± 11	22 ± 15	35 ± 22
0.7 μg/h	20 ± 16	18 ± 15	19 ± 17	21 ± 18	15 ± 12	29 ± 23
7 0 μg/h	14 ± 24	12 ± 16	9 ± 11	–	24 ± 10	–

A.629 The efficacy of pre-incisional and post-incisional bupivacaine infiltration on postoperative pain in inguinal herniorrhaphies

Ş Ozcan, M Pınarlıdağ, H. Yağmurdur, M Parpucu, N Inan, N Unal
The Ministry Of Health Ankara State Hospital Departement of Anaesthesiology, Turkey

Background & Goal of Study: Control of postoperative pain is an important factor in preventing the modification of the excitability of the dorsal horn neurons (1) The aim of our study is to compare preincisional and postincisional infiltration of the surgical area with bupivacaine.

Materials & Methods: With the approval of the ethic committee and informed consent, 24 male patients ages between 25–70 for elective lateral inguinal hernia repair were included in the study. All patients received balanced inhalational anaesthesia The patients were randomized into two groups Preincisional group (Group I, $n = 12$) and postincisional group (Group II, $n = 12$) Group I consisted of patients receiving 40 ml 0 25% bupivacaine wound infiltration at 5 min before skin incision and the same procedure was performed for group II before skin closure. Postoperative pain medication included meperidin (IM) or metamizol (PO) as needed 48 hours after surgery the pain was recorded with visual analogue scala (VAS) and verbal rating scala (VRS). First analgesic requirement time and total analgesic consumption were recorded Comparison between groups was based on the Mann-Whitney-U test and nonparametric methods of variance analysis

Results & Discussion: Postoperative pain scores were lower in the preincisional group than in the postincisional group although the difference had not been significant ($p > 0\ 05$). First analgesic requirement time was significantly shorter in group I compared to group II ($P < 0.05$) The amount of total analgesic used was highest in postincisional group ($p < 0\ 05$) The findings of Ejlersen at al (2) and the findings in our study suggest that the inhibition of peripheral sensitization may be of major importance in avoiding the development of acute pain and may explain why prevention is important in handling operative pain

Conclusion: We conclude that preincisional infiltration of the surgical wound with bupivacaine is a more effective method of providing postoperative analgesia compared to postincisional infiltration

A.630 Analgesic effect of low-dose ketamine administered during knee surgery

C. Menigaux, X. Dupont, M. Chauvin. *Anes. Dept , A PARE Hospital 92100 Boulogne, France*

Background and Goal of the Study: Ketamine (K) is in low doses an uncompetitive NMDA antagonist. The purpose of this study was to evaluate the analgesic effects of K in patients undergoing knee crucrate anterior ligamentoplasty under arthroscopy.

Materials and Methods: 45 ASA 1–2 patients were enrolled in a prospective, double-blind and randomized study. They were allocated in 3 groups: group 1 (G1) received 0.15 mg/kg of K after induction and before surgical incision and placebo at the end of surgery; group 2 (G2) received placebo after induction and before surgical incision and 0 15 mg/kg of K at the end of surgery; group P (GP) received placebo at the beginning and the end of surgery. All the patient were anesthetized with propofol for induction and maintenance. Sufentanil (bolus of 0 2 μg/kg then 0.2 μg/kg/h) was started 10 min after incision Postoperative analgesia was provided by IV patient controlled analgesia morphine (bolus: 1 mg, lockout period: 5 min). Pain was assessed using 10 cm visual analogic scale (VAS) and morphine consumption was noted during 24 h postoperatively every 4 hours and during first physiotherapy period at day 1. Delay of first demand and side effects were recorded. Results were analysed by ANOVA and unpaired-t-test $p < 0.05$ was considered significant.

Results: Morphine consumption was continuously less for the 24 h of the study period and during physiotherapy for patients who received K either before or after surgery compared to placebo (table) However, no difference appeared between groups 1 and 2. VAS pain scores at rest were similar between groups. During the first physiotherapy period pain score were similar between groups but morphine consumption was higher in GP with a lesser flexion (table)

Table

	Delay of first demand (min)	Total morphine dose (mg)	First physiotherapy period	
		first flexion (°)	M (mg)	
G1	27 2 ± 23*	28 2 ± 18 4*	47 ± 13*	1 2 ± 0.4*
G2	29 8 ± 22*	24 2 ± 17 8*	46 5 ± 12*	1.4 ± 0 7*
GP	9.5 ± 7 2	49 7 ± 24 1	35 ± 10	3 8 ± 1.7

* $p \leq 0\ 05$ with GP, mean ± sd

Side effects were comparable in three groups. No psychic disorder appeared in K groups

Conclusion: No preemptive effect was obtained with K in the present study. However, in two groups, peroperative administration of a low dose K had the benefit to decrease postoperative morphine consumption and to improve analgesia during physiotherapy.

A.631 Pre-emptive analgesia induced by epidurally administrated liposome encapsulated bupivacaine

S Van Melkebeke, V Umbrain, M. Matic, F. Camu. *Free Flemish University of Brussels Medical Center Dept. of Anaesthesiology, Brussels, Belgium*

Introduction: Postoperative complications can be reduced with extended monitoring and pain relief. Liposomes encapsulated anaesthetics get us nearer to this concept as the encapsulation of bupivacaine into liposomes resulted in a bupivacaine release of 48 h. We compared the morphine-sparing effect of preoperative epidural liposome associated bupivacaine administration (group Lipo) versus preoperative epidural bupivacaine administration (group Bupi) in a double blind placebo controlled clinical setting.

Methods: After local Ethics Committee Approval and informed consent 30 patients, undergoing major abdominal surgery were divided in three groups: each group received before surgical incision and after a 3 ml epidural test-dose of lidocaine 2% with 1/200.000 adrenaline (L2-level), an epidural injection of either 10 ml liposome associated bupivacaine, plain bupivacaine or saline (group Placebo). A TIVA with propofol, sufentanil and vecuronium standardized to all groups ensued. After surgery, decuranization and regaining consciousness pain sensation was monitored with the Visual Analog Scale (VAS) and the level of dermatomal block was assessed by loss temperature and pinprick. All patients received a PCA-pump with morphine (2 mg bolus, lock out time 5 min, maximal dosis 16 mg/4 h) to alleviate their pain. Differences between groups were identified using ANOVA. The Newman-Keuls test was used to detect intra-group differences.

Results: The three groups were homogenous regarding population characteristics and surgery time. The spread of sensory dermatomal block was an overall 2 to 3 dermatomes smaller in group Bupi. The VAS were lower and the morphine consumption less (−35% vs placebo, P = 0.13) in the patients of group Lipo vs group Placebo. On the contrary, no differences were observed between the VAS scores of group Bupi and Placebo though the morphine consumption was reduced by 15% in group Bupi (P = NS.)

Summary: Pre-surgical epidural administration of liposome encapsulated bupivacaine reduces post operative pain and morphine requirements when compared to epidural bupivacaine, suggesting a prolonged activity of the liposomal solution

A.632 Pre-emptive analgesia with ropivacaine during breast reconstruction

P. Di Marco, M.G Costa, G. Della Rocca, M Antonini, M Mantti,
C. Coccia, L Pompei, F. Pugliese, F.R. Grippaudo. *University of Rome "La Sapienza", Istituto di Anestesia e Rianimazione Dir.: Prof. A Gasparetto, Italy*

Introduction: Preemptive analgesia is an antinociceptive treatment that prevents the establishment of altered central excitability due to high intensity noxius stimuli (1). Experimental data suggests that preadministration of local anesthetics decrease hyperplasticity of the central nervous system and postoperative pain (2) Clinical investigations do not always support experimental data (3). The aim of this study is to evaluate the efficacy of preemptive analgesia, with a correct regional anesthetic technique.

Methods: Twenty women, ASA I–II, scheduled for breast reconstruction were randomly divided in two groups: 10 patients received preemptive analgesia with ropivacaine infiltration 1.5 mg/mL, (100 mL) before the skin incision (group A) and 10 pts in which infiltration was performed with normal saline (group B). In all patients, anesthesia was induced with propofol O_2:N_2O (30:70), vecuronium bromide, isoflurane and maintained with isoflurane. Postoperative pain was evaluated by a blinded observer using VAS in the recovery room and during the following 24 hours postop. Analgesic requirement during this period, if necessary, was recorded. Statistical analysis was performed by ANOVA and T-test. Significance was measured at a level of $p < 0.05$.

Results and Discussion: In group A (VAS 0–1) no pt required any postop analgesia. In group B, all pts (VAS 3–4) required ketorolac for pain control ($p < 0.001$). As reported by Kissin (3), the results of this study suggest that clinical impressive effects of preemptive analgesia are observed when the blockade of noxious stimuli is complete and extended into the initial postop period.

Conclusion: Our results suggest that preop extended infiltration with ropivacaine correctly performed in time, volume and concentration leads to a successfully postop pain control.

A.633 Olfen (diclofenac sodium) for postoperative analgesia after gynaecological surgery

A. Sondore, I Vanags, E. Daugulis, I. Kokars. *Latvian Medical Academy, Riga, Latvia*

Background and Goal of Study: NSAIDs have been found to be effective in post-operative analgesia [1, 2]. This study was performed to evaluate the analgesic efficacy of Olfen (O), and its effect on postoperative requirement for Fentanyl (F), as well its safety

Material and Methods: 30 women, ASA I–II, aged 25–59 yrs, scheduled to abdominal hysterectomy were randomly allocated to standardized premedication and neuroleptanaesthesia. One group of patients (*O*, n = 15) received O in dose 75 mg i/m perioperatively, another, control (*C*, n = 15) – normal saline. Rectocaps of O (100 mg) or 75 mg i/m were given on-demand to patients of *O* group in the first and second postoperative days. VAS (0–10 cm), F requirement, postoperative nausea and vomiting (PONV) or other side effects were registered at awakening and 4, 8, 12 h. Overall the F consumption was evaluated after 24 h. Measurements of bleeding time (BD), platelet count (PC) were investigated before surgery and on 3-d and 7-th day.

Results: Both groups were comparable as to demographic data and duration of surgery (75–80 min.) They needed the same amount of F (0 4 mg). After awakening 20% of *O* group were completely without pain, 40% expected mild pain (VAS 2–3 cm), 33.3% – moderate pain (VAS 4–5 cm), 6.67% – severe pain. At the same time no patient of *C* group had no pain. Mean pain intensity on the awakening in *C* group was between 4–7 cm in VAS; 20% of patients had very severe pain (VAS > 7 cm). During first 4 h after surgery 46.6% of *O* group had no need for analgesia, but 54.4% were given 0.1 mg of F. During 12 h after surgery 33.3% of *O* group had good analgetic effect from 0.75 mg i/m and had no need for opioid, 53.3% were given F 0.1 mg and 13.4% – F 0.2 mg When compared with saline, *O* resulted in a reduction of the cumulative F dose by 1.8 times at 4 h, by 2.5 times at 12 h and by 2.7 times at 24 h 40% in saline group required antiemetic compared with 6.67% in *O* group. There were no significant changes and differences between the groups in BT and PC No bleeding complications occurred in *O* group

Conclusions: 1. O reduces pain and need for opioids after abdominal hysterectomy during the first 4–12 h postoperatively. 2 The use of O in the first postoperative days produces effective analgesia 3. O has been found to be safe for acute postoperative pain relief after abdominal hysterectomy.

A.634 Validation of predictors of postoperative pain

C. Mamie[1], T Ross[1], M. Bernstein[2], A. Morabia[2], A Forster[1].
[1] *Departement of Anesthesiology;* [2] *Division of Clinical Epidemiology, University Hospital, Geneva, Switzerland*

Background and Goal of the Study: In a previous study(1), behavioral and psychological factors predictive of the intensity of postoperative pain were investigated on a reference group of 300 patients. It concluded that bad quality of sleep and fear of postoperative pain increased the odds of severe pain by more than 2.5 folds The present study was performed to validate these results on 2 other groups of patients

Patients and Methods: Validation group 1 included 100 patients undergoing orthopedic or intraperitoneal procedures with various anesthetic and analgesic techniques. Validation group 2 included 60 patients (30 undergoing total knee prothesis and 30 undergoing colectomy) with the same anesthetic and analgesic techniques All patients were 18 to 74 years old and answered the same preoperative and postoperative questionnaires used for the reference group. The model of logistic regression developed in the reference group was applied on the 2 validation groups.

Results: (table). While bad quality of sleep remained highly significative in the 2 validation groups, fear of postoperative pain was not validated and gender male increased the risk of postoperative pain only in the validation group 1.

Discussion and Conclusion: Bad quality of sleep reported by the patient emerged as a strong predictor of severe postoperative pain The anesthesiologist should take into account this factor, easy to assess in clinical practice and consider it in the management of postoperative analgesia. Fear of postoperative pain and gender appeared as risk factors, but require further investigations including all potential confusion factors

Odds ratio of high pain compared to low pain in the reference group and the 2 validation groups

A.635 Postoperative pain assessment: methodology for VAS curve analysis

Françoise M. Bardiau, Monique M Braeckman, Jean G. Boogaerts.
Departments of Nursing, Biostatistics and Anaesthesiology, University Hospital Centre, Charleroi, Belgium

Background and Goal of Study: The routine assessment of postoperative pain represents a basic tool for implementing a quality assurance project. The purpose of this study is to describe a methodological approach of visual analogue scale (VAS) curve analysis corresponding to a internal audit The aim is to define analytical tools pointing out problems with postoperative analgesia in selected surgical departments

Materials and Methods: One thousand five hundred patients, undergoing various surgical procedures, were enrolled Patients were evaluated for pain intensity at rest, using VAS during 72 hours in the postoperative period VAS curves registered were pooled in regard to selected surgical specialties. Comparison of VAS curves were conducted using four end-points: VAS max peak amplitude of VAS (cm), T max: time to peak of VAS (h); AUC: area under the time-VAS curve during intervals of 24 hours (cm × h), slope of VAS curve regression line (%). Statistical analysis Data Mean ± SD ANOVA and Student's *t* tests $P < 0.05$ significant

Results and Discussion: Results are presented in Table

	Ortho	Abdo	Plast	O R L	Gyn	Opht	Neuro	Uro
n	466	340	112	110	99	84	76	40
VAS max	3.1	2.5	2.6	2.1	3.0	0.8	3.7	1.9
	±2.3	±2.6	±2.7	±2.1	±3.0	±2.0	±2.8	±2.7
T max	12	1	1	6	1	0	12	4
AUC→24 h	56.6	51.2	47	36.4	57.6	14.2	73.2	32.5
AUC→48 h	46	35.4	34.5	21.7	43.9	6.2	60.9	26.9
AUC→72 h	35.4	19.6	21.9	7.1	30.2	0	48.6	21.4
Slope	−1.84%	−2.75%	−2.18%	−2.54%	−2.38%	−1.38%	−2.14%	−0.96%

Our study describes four end-points: VAS max and AUC determine severity of acute pain, T max points out the timing of the VAS peak, and the slope of regression line could be considered as the reflect of the natural history of postoperative pain. These items rapidly permit pointing out problems with postoperative pain management at the scale of the hospital.

Conclusion: Designing tools to guide physicians and nurses to initiate and modify analgesic treatments expertly, is an immediate challenge for implementing a quality assurance project.

A.636 Implementation of a postoperative pain protocol: a stepwise approach

M. Verlaeckt, E. Vandermeersch, J. Van Canneyt, M. Puylaert, C De Deyne, R Heylen, K. Vissers. *Ziekenhuis Oost-Limburg, Genk, Belgium*

Introduction: A good postoperative pain management can reduce postoperative morbidity. Our institution consists of a 840 beds regional hospital with a reference function. The Departement of Anesthesiology consists out of 30 staff members and assistants We tried to implement a postoperative pain protocol for: improvement of postoperative pain scores, standardization of prescriptions, fine adjustments of individual pain treatment by the Nursing Department and prevention of postoperative pain by a regular score system.

Aim of the Study: In our protocol for postoperative pain management we used a multimodal medication scheme, which is based on the WHO analgesic stepwise approach. The base of the protocol is peripheral acting analgesic (proparacetamol and/or NSAID) administrated on regular basis Using an algorithm that includes the pain score, degree of sedation, the respiratory function and the circulatory state, the ward nurse can decide on an independent, but safe medicolegal method to administrate an opioid if pain rating scores are too high By scoring the patients on a regular basis we can prevent severe postoperative pain.

Method: The evaluation of our protocol consists of two phases:

- Phase I: using a descriptive questionnaire the postoperative patient is evaluated. This phase is before implementation of our protocol from June 1996 until October 1996 100 postoperative patients were evaluated
- Phase II where we will evaluate after implementation of the postoperative pain protocol

Results: In general we believed that postoperative pain management without algorithms was satisfactory. But in this phase I-evaluation we found that 14 patients out of 100 scored the postoperative pain treatment as clearly insufficient. All kind of surgery was included. Preoperative information about postoperative pain was only sufficient in 22% of all patients. 30% of the patients were evaluated by the ward nurses on a numerical pain rating score. Only 50% of the patients are dismissed from the PACU with a pain score less than 5/10 In the first 24 hours 40% of the patients experienced moderate to severe pain (VAS > 4).

Conclusion: We believe that a good postoperative pain management has to be based on a multimodal postoperative pain algorithm, where nurse controlled analgesia can ameliorate postoperative pain scores

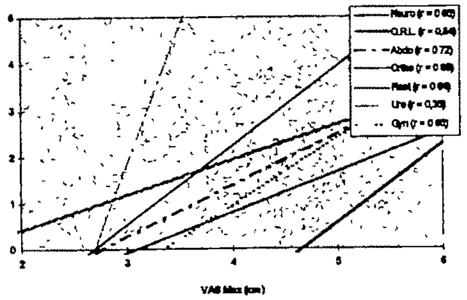
A.637 Acute pain management: description of a performance quality indicator

Françoise M. Bardiau[1], Monique M Braeckman[2], Jean G Boogaerts[3].
Departments of [1] *Nursing;* [2] *Biostatistics;* [3] *Anaesthesiology, University Hospital Centre, Charleroi, Belgium*

Background and Goal of Study: The traditional method of providing postoperative analgesia is the use of opioids But, unrelieved acute pain is still reported to be a rather common clinical problem which may be related to inadequate routines for treatment (1) The aim of this study was to describe a performance indicator of pain management quality, permitting comparison between different surgical specialities at the scale of a general teaching hospital.

Materials and Methods: 1,500 postsurgical patients above 15 years old were enrolled Visual Analogue Scale (VAS) scores at rest and *pro re nata* opiate administration, expressed in mg morphine equivalents, were recorded every 4 hours during 72 hours in the postoperative period. The relationship between VAS scores and morphine amounts given was studied in different surgical specialities Statistical calculations included descriptive statistics, and weighted Pearson correlation coefficients.

Results and Discussion: Correlation coefficients (r) among some surgical specialities are presented (Figure).



The correlation coefficient (r) between VAS scores and morphine amount given at the same time, permits comparison between the different surgical teams concerning the quality of acute pain management. It represents an interesting tool for internal audit, to maintain the focus on effective pain control as an important institutional clinical priority

Conclusion: We describe a reliable performance indicator of acute pain management quality assessment.

A.639 Variables influencing analgesia during ESWL-treatment

J.B. Marcelo, I.A. Schneider, G G Tailly, K.R. Hente *KLINA, Antwerp, Belgium*

A prospective study of analgosedative consumption using a PCA-device

Patients treated with the new third-generation electromagnetic lithotriptors no longer require general or regional anesthesia. However, there is need for analgosedation Demographic and pathology-specific factors may influence the consumption of these drugs, as well as the occurrence of side-effects. The aim of the study was to identify these factors

During a 7-month period, 152 calculus-treatments with the new Dornier U/50 machine were recorded (one per patient or per localisation). For each patient (ASA I–III), demographic and stone- and therapy-related data were recorded. Patients were induced with prop. 1 mg/kg and alfentanil 0 01 mg/kg When needed, they could administer themselves via PCA a bolus of prop. 0.25 mg/kg and alfentanil 0 005 mg/kg with a lock-out of 5 minutes (1) Drug-consumption and occurrence of O^2-desaturation and/or ventricular premature beats (VPB) were recorded and related to the different parameters

There is a tendency to a slightly greater need of analgesia in patients treated for distal ureteral stones compared to those with prevesical or pyelo-ureteral-junction (PUJ) localisations, although not statistically significant. ESWL-treatment for tendinitis calcarea of the shoulder needed approximately as much analgesia as PUJ-stones. Women and younger people tended to consume more alfentanil. A significantly greater consumption occurred with an increasing number of shockwaves ($p = 0.0001$) and with a greater exposed surface area of the stone ($p = 0.0037$, both S-N-K test), but not with an increasing percentage of maximum applicable energy. SaO^2 <90% was seen more often in people over the age of 60 ($p = 0.054$, 2-tailed Fisher's Exact test) and a tendency towards the same was also noted in the more obese The occurrence of VPB was significantly higher in calyx-, pyelum- and PUJ-stones than in the more distally located ($p = 0.001$ chi-square), but there was no correlation with O^2-desaturation.

Using this method of analgosedation, which was very satisfying for both patients and physicians, we were able to determine some factors indicating the need for pain control and identifying patients at risk

A.242 Does PEEP induce additional alveolar recruitment when set above the lower inflection point of the pressure-volume curve?

S. Vieira, L. Puybasset, Q. Lu, J. Richecoeur, P. Cluzel, P. Conat, J J Rouby. *Dept. of Anesthesiology, La Pitié-Salpêtrière, Paris, France*

Background and Goal of the Study: Best PEEP is usually considered as equal to the lower inflection point (LIP) determined on the pressure volume (P-V) curve plus 2 cmH_2O (1). The goal of this study was to determine whether PEEP induces a further alveolar recruitment when set 7 cmH2O above the LIP.

Patients and Methods: 14 hypoxemic patients (age = 61 ± 13 yrs, $PaO_2 = 166 \pm 94$ mmHg; and $Qs/Qt = 40 \pm 12\%$ at $FiO_2 = 1$) were included Three conditions were tested ZEEP, PEEP = LIP + 2 cmH_2O (PEEP1 = 11 ± 1 cmH_2O) and PEEP = LIP + 7 cmH_2O (PEEP2 = 16 ± 1 cmH_2O). In each condition, hemodynamic and respiratory parameters were measured, a thoracopulmonary P-V curve was constructed and a CT scan at end expiration was performed. Lung volumes were determined from the CT scan by the frequency histogram analysis technique (2). Results are presented as mean ± SD.

Results and Discussion: PaO_2 increased by 61 ± 85% in PEEP1 and by 108 ± 120% in PEEP2 ($p < 0.05$) and Qs/Qt decreased by 16 ± 13% in PEEP1 and 28 ± 11% in PEEP2 ($p < 0.05$). The volume of non-aerated lung (CT number between −100 and +100 HU) decreased from 866 ± 419 ml in ZEEP to 739 ± 463 ml in PEEP1 and to 534 ± 286 ml in PEEP2 ($p < 0.05$) corresponding to an alveolar recruitment of 25 ± 6% and 38 ± 6%, of consolidated lung respectively ($p < 0.05$). The volume of aerated lung (CT number between −1000 and −500 HU) increased from 651 ± 723 in ZEEP to 1337 ± 1230 in PEEP1 and 1695 ± 1179 in PEEP2 ($p < 0.05$). The volume of overdistended areas (CT number between −1000 and −900 HU) increased from 11 ± 18 ml in ZEEP, to 60 ± 101 ml in PEEP1 and 151 ± 240 ml in PEEP2 ($p < 0.05$). The slope of the thoraco-pulmonary P-V curves did not change between the three conditions

Conclusions: PEEP induces a further alveolar recruitment when set largely above the LIP. This additional alveolar recruitment is associated with a slight but significant overdistension.

A.298 Adding low-dose ketamine to general anaesthesia suppresses the serum IL-6 response after cardiopulmonary bypass

L. Roytblat[1], D Talmor[1], M. Rachinsky[1], L. Greemberg[1], A Appelbaum[2], A. Pekar[2], A. Douvdevani[3], Y. Shapira[1], G. Gurman[1]. [1]*Division of Anaesthesiology;* [2]*Department of Cardiothoracic Surgery;* [3]*Department of Nephrology, Soroka Medical Centre, Ben-Gurion University of the Negev, Beer-Sheva, Israel*

Background and Goal of Study: Cardiopulmonary bypass (CPB) has been proposed as a model for studying the inflammatory cascade involved in the systemic inflammatory response syndrome (SIRS) SIRS seems to result from overwhelming inflammation which is caused by excessive release of cytokines. Serum interleukin-6 (IL-6) concentration appears to be a good indicator of activation of the inflammatory cascade and predicts subsequent organ dysfunction and death (1)

Opioid drugs and local anaesthetics seem to have little effect on the IL-6 response (2). Experimental data has shown that ketamine inhibits nitric oxide (NO) production via inhibition of TNF. In the present study we compared the effects of adding 0.25 mg/kg of ketamine to general anaesthesia on serum IL-6 levels during and after elective coronary artery bypass grafting (CABG)

Methods: Thirty-one patients undergoing elective CABG were randomized to one of two groups and prospectively studied in a double blind manner. The protocol for the study was approved by the local ethics committee The patients received either ketamine 0 25 mg/kg or a similar volume of normal sa'ine as an addition to high dose fentanyl anaesthesia Blood samples for analysis of serum IL-6 levels were drawn before the operation, at termination of CPB as well as at 4, 24, 48 hours following surgery and on the 3rd, 4th, 5th, 6th, 7th and 8th days postoperatively.

Results: Low-dose ketamine suppressed the serum IL-6 response immediately following CPB and at 4, 24 and 48 hours postoperatively ($p < 0.05$). During the first 7 days following surgery the serum IL-6 levels in the ketamine group were significantly lower than in the control group ($p < 0.05$). On day 8 after surgery IL-6 levels in both groups had returned to their baseline values. In this study fewer major postoperative complications were found in the ketamine group than in the control group

Conclusions: We conclude that the addition of low-dose ketamine to high dose fentanyl reduces the IL-6 response to CABG.

A.345 Systemic haemodynamic effects ofhypertonic saline 7.2% in patients with raised intracranial pressure

F Munar[1], A.M Ferrer[1], M A Poca[2], M Báguena[3], B. Bermejo[4], J Sahuquillo[2], A Garnacho[3]. [1]*Neurotraumatology Research Unit; Departments of* [2]*Neurosurgery,* [3]*Neurotraumatology Intensive Care Unit;* [4]*Department of Preventive Medicine, UK*

Background & Goal of Study: In spite of data suggesting a potential role for hypertonic saline solutions (HSS) in the treatment of intracranial hypertension (ICH), only a few studies have been done on humans[1,2] The goal of this study is to evaluate the effects during 2 hours produced by a 15 minute infusion of 7.2% on the ICP and systemic hemodynamics

Materials & Methods: A prospective study was carried out in 14 consecutively admitted patients with an acute head injury and raised intracranial pressure within the first 72 h after injury Each patient received an infusion of 7 2% HSS (1233 mEq/L, volume 1.5 ml/kg) during fifteen minutes when the ICP was greater than 15 mmHg Heart rate (HR), mean arterial blood pressure (MABP), cardiac index (CI), pulmonary artery occlusion pressure (PAOP), systemic vascular resistance index (SVRI), intracranial pressure (ICP), cerebral perfusion pressure (CPP) were collected before infusion of 7.2% HSS and at 5, 30, 60 and 120 minutes after the infusion (T_5, T_{30}, T_{60}, T_{120}) Core temperature was measured before infusion and at T_{120}. Urine output was measured at T_{120}. Baseline values were compared to the subsequent values using Wilcoxon rank sum text for difference. Values are given as the mean ± SD.

Results: Mean age in the group was 34 ± 16 years. The mean initial Glasgow Coma Scale equaled 7 ± 3. Mean ICP before HSS infusion equaled 26 mmHg and at T_{120} equaled 18 mmHg ($p < 0\ 001$). CPP rose significantly ($p < 0.05$) during the first hour after infusion HR increased significantly ($p < 0\ 05$) during the first thirty minutes after the infusion. There was no significant change in the MABP ($p > 0.0929$) during the study period The SVRI fell ($p \leq 0.05$) and the CI ($p < 0\ 05$) increased, both significantly during the first hour following the infusion PAOP increased ($p < 0\ 05$) five minutes after the infusion Urine output and core temperature did not change significantly.

Conclusions: The administration of 7.2% HSS decreases SVRI, expands plasma volume and increases CI. The fact that 7.2% HSS significantly decreases raised ICP without significantly decreasing MABP or significantly increasing urine output supports the idea that its administration could be more beneficial than other drugs in patients with traumatic brain injury, ICH and hypovolemia.

Supported by Grants 96/1783 and 98/1385 from the Fondo de Investigaciones Sanitarias de la Seguridad Social (FISS).

A.387 Continuous lumbar plexus block: where does the catheter go?

Xavier Capdevila, Philippe Biboulet, Yves Barthelet, Yves Ryckwaert, F. d'Athis. *Department of Anesthesiology, Lapeyronie University Hospital, 34295 Montpellier, France*

Background and Goal of Study: Continuous lumbar plexus block, using the anterior approach, is widely used for post operative analgesia after proximal lower limb surgery Authors claim that they have a lumbar plexus block without supporting evidence that they have succeeded in positioning the catheter in proximity to the lumbar plexus The aim of this study was to evaluate the characteristics of catheter threadings from below the inguinal ligament and the correlations between the catheter position and effective sensory and motor blockades.

Patients and Methods: After institutional approval, 86 consecutive patients scheduled for proximal lower limb surgery were enrolled. After general anesthesia, once the patients were awakened and extubated, the femoral nerve was located using a nerve stimulator and 16–20 cm of a catheter were placed in the fascial sheath of the femoral nerve. 3 ml of contrast media were injected in the catheter and a frontal pelvic region's radiograph was taken. The local anesthetic solution used for all patients was 30 ml of an equal volume mixture of 2% lidocaine with epinephrine and 0 5% bupivacaine. Sensory blockade (cold and pinprick tests) was evaluated in the three nerve territories of the thigh 30 min after injection as well as motor blockade of the femoral (F) and oturator (O) nerves Statistical comparisons were performed using the Mann-Withney test

Results: Six block failures were noted (7%) (4 catheter tips at the iliac creast, 1 catheter migration in the sartorius muscle and 1 under the abdominal muscles fascia). The tip of the catheter reached the lumbar plexus area in 19 patients (22%) and was under the fascia iliaca in 61 patients (71%). A '3 in 1' block was obtained in 90% of cases when the catheter reached the lumbar plexus and in 31% when the catheter was under the fascia iliaca ($p < 0.05$). When we compared external (over the iliacus muscle) and internal (in the psoas muscle area) subfascial catheter tip positions, '3 in 1' block was achieved in respectively 18% and 47% of the patients ($p < 0.05$), sensory blockade of the F nerve was obtained in 94% and 100%; of the O nerve in 18% and 78% ($p < 0\ 05$); of the lateral femoral cutaneous nerve in 94% and 46% ($p < 0\ 05$) of the patients.

A motor blockade of the F nerve was obtained in 84% of the patients and of the O nerve in 41% of them.

Discussion and Conclusion: During a continuous lumbar plexus block via the anterior approach, the threated catheter reached rarely the lumbar plexus area The quality of the sensory blockade of each nerve depends of the position of the catheter under the fascia iliaca.

A.589 The efficacy of intravenous regional guanethidine blockade in the treatment of post-traumatic algodystrophy

J.A. Livingstone, R M. Atkins *University. Dept of Orthopaedic Surgery, Bristol, UK*

Background: The aim of this study was to determine the efficacy of intravenous regional sympathetic blockade (1) in the early treatment of algodystrophy of the hand following Colles' fractures.

Methods: Between March 1995 and December 1996 adult patients with Colles' fractures were assessed for features of algodystrophy at nine weeks from fracture (2) Pain and finger tenderness were evaluated using verbal pain scores and dolorimetry, vasomotor instability by questionnaire, finger stiffness by finger goniometry, hand and finger swelling by water displacement and arthrocircometry and grip strength using a grip dynamometer Patients with algodystrophy were entered into a prospective, randomised, double blind trial of serial intravenous blocks with either a 15 mg guanethidine in 30 ml prilocaine or b. 30 mls normal saline Following each block patients were assessed at 24 hours, 48 hours and one week Serial blocks were administered at weekly intervals until dolorimetry ratios returned to normal or a maximum of four blocks had been administered Patients were then followed up for six months

Results: 377 patients with Colles' fractures were assessed and 82 patients identified with algodystrophy 27 patients received serial intravenous blocks containing guanethidine and prilocaine and 30 patients received serial blocks containing normal saline. There was no difference in the number of blocks administered or in the proportion of patients who responded to treatment between to the two groups No significant difference was seen in the improvement of pain, finger tenderness, finger stiffness, swelling or grip strength between the two groups. Patients treated with guanethidine had significantly worse vasomotor instability scores at 30 weeks compared with the normal saline group

Conclusion: The results of this study suggest that intravenous sympathetic blockade with guanethidine has no significant effect on pain and does not alter the natural history of algodystrophy following Colles' fracture.

A.638 Effects of regional analgesia on long-term surgical outcome after knee surgery

Y. Barthelet, X Capdevila, P. Biboulet, J Rubenovitch, F. d'Athis.
Department of Anesthesiology and Intensive Care "A", Montpellier, France

Goal of Study: Answer to the question Can an analgesic technique influence the surgical outcome of knee joint surgery?

Materials & Methods: After informed consent and IRB approval, 56 ASA class 1 or 2 patients scheduled for knee surgery (arthroplasty or arthrolysis) were randomly divided into 3 groups according to the postoperative analgesic technique. Following a standardized general anesthesia, in group A (n:19), IV-PCA morphine was used (1 mg doses, lockout interval of 7 min). Continuous femoral block (CFB) was used in group B (n 20): an initial dose of 30 ml of 2% lidocaine with 1/200 000 epinephrine was administered via a femoral catheter, followed by a 48 hours continuous infusion of 1% lidocaine + 0.03 mg/ml morphine + 2 μ/ml clonidine (rate 0.1 ml/kg/hour). Epidural analgesia (EA) was used in group C (n:17): 2 mg morphine and 10 to 15 ml of 2% lidocaine were administered in the epidural space in order to obtain a T10 spread, followed by continuous infusion as group B Daily sessions of 10 hours of continuous passive motion

(CPM) were started on day 1. The intensity of pain was assessed, twice a day during mobilization, using a visual analog scale (VAS). The maximal knee flexing obtained during CPM was compared with the targeted level prescribed by the surgeon. The maximal amplitude of knee flexion was assessed on day 5 upon hospital's discharge and at the end of the first and third months. The stay in rehabilitation center (in days) was noted. Results are expressed as median values (range). P value < 0.05 was considered significant.

Results & Discussion: There was no demographic difference between groups. The VAS values in group A were significantly higher than those of groups B and C. Groups B and C performed significantly better postoperative knee mobilization than group A [Table I]. The resulting degree of knee flexion noted on day 5 and upon discharge from the hospital, was higher for the patients of groups B and C than those of group A, but there was no significant difference on first and third month [Table II]. However, duration of rehabilitation was significantly longer in group A [50 (30–80)] than in group B [40 (21–60)] and C [37 (30–45)]. Then, regional analgesia, by providing effective pain relief during CPM, improves early rehabilitation and convalescence.

Table I Quality of early rehabilitation $^{\#}p < 0.05$ vs CFB and EA

	PCA		CFB		EA	
	D1	D2	D1	D2	D1	D2
Mobilization (% of surgeon's prescription)	$75^{\#}$ (0–100)	$80^{\#}$ (0–100)	100 (66–100)	100 (66–100)	100 (92–100)	100 (95–100)

Table II Knee flexion (degree). $^{\#}p < 0.05$ vs CFB and EA

	Day 5	Discharge	Month 1	Month 3
PCA	60 (45–80)$^{\#}$	80 (60–100)$^{\#}$	90 (80–100)	125 (90–140)
CFB	80 (55–90)	90 (60–100)	95 (90–105)	125 (95–130)
EA	85 (40–105)	90 (60–105)	105 (100–130)	130 (110–140)

Conclusion: Following major knee surgery, both CFB and EA enhance the quality of early rehabilitation and contribute for hastening of convalescence and reduction in overall hospital stay. However, regional analgesia do not improve the long term surgical outcome when compared with IV-PCA. Cost saving should be assessed.

SUBJECT INDEX

3-In-1 Block, 112 (A.385)
3D reconstruction, 163 (A.565)

Abdominal aortic aneurysm, 59 (A.199)
Abdominal aortic surgery, 1 (A.1), 1 (A.4)
Abdominal wall retractor, 76 (A.256)
ACEI therapy, 58 (A 197)
N-Acetylcysteine, 64 (A.214), 157 (A.538)
Acidosis, 49 (A 168)
Acoustic neurinoma, 136 (A.464)
Active oxygen species, 88 (A.299)
Acupuncture, 170 (A.592)
Acute brain injury, 101 (A.346)
Acute inflammation, 125 (A.428)
Acute lung injury, 69 (A.233), 73 (A.247), 160 (A.551), 161 (A 556)
Acute myocardial failure, 51 (A 174)
Acute normovolaemic haemodilution, 82 (A.277)
Acute pain, 182 (A.633)
Acute pain management, 183 (A.634)
Acute renal failure, 6 (A 22)
Adenosine, 170 (A.588)
Adenosine, trauma, 98 (A.334)
Adenotonsillectomy, 143 (A.490), 146 (A 498)
Administration, epidural, 121 (A.417)
Administration, epidural: IV PCA, 182 (A.631)
Administration, inhalation, 162 (A.561)
Administration protocol, 36 (A.122)
Admission, 3 (A.11)
Adolescents, 144 (A.491)
α_2-Adrenergic agonists, clonidine, 27 (A.93), 110 (A.376), 167 (A 578), 167 (A.579), 173 (A 600)
Adrenomedullin, 85 (A.288)
Adult respiratory distress syndrome, 163 (A 562), 163 (A 563), 163 (A.564)
Adverse effects, 147 (A.502)
Age, gender, 33 (A 114)
Ageing, 104 (A.356)
Airway management, difficult, 23 (A 79)
Airway pressure, 73 (A.247)
Airway separation, 23 (A.80)
Airways, 74 (A.250)
Akinesia, 105 (A 359)
Alcohol, 13 (A 45)
Alfentanil, 64 (A.217), 71 (A.238), 130 (A.447)
Algodystrophy, 185 (A.689)
Allergic reactions, 81 (A 274)
Allergy, tryptase, 129 (A.442)
Allogeneic blood transfusion, 82 (A.277)
Alveolar oxygen partial pressure, 77 (A.262)
Ambulatory, 142 (A.487)
Ambulatory anaesthesia, 12 (A.40), 171 (A.595)
Ambulatory practice, 147 (A.503)
Ambulatory surgery, unanticipated admissions, 14 (A.48)
Anaesthesia, 7 (A.25), 14 (A.47), 19 (A.64), 28 (A.94), 32 (A.109), 34 (A 116), 44 (A.149), 51 (A.175), 61 (A 207), 80 (A.273), 76 (A.256), 106 (A 362), 112 (A.384), 117 (A 402), 117 (A 403), 147 (A 502), 151 (A.516)
Anaesthesia, ambulatory, 11 (A.38)
Anaesthesia, complications, 100 (A.341)
Anaesthesia, continuous, 116 (A.398)
Anaesthesia, day case, 10 (A 36), 11 (A 39), 12 (A.42), 15 (A.53), 16 (A.56)
Anaesthesia, day case: premedication, 17 (A.58)
Anaesthesia, depth, 37 (A.125), 37 (A.126), 39 (A.134)
Anaesthesia, difficult, 22 (A 77)
Anaesthesia for elderly patients, 2 (A 6)
Anaesthesia for laparoscopy, 2 (A 6)
Anaesthesia, general, 19 (A.65), 22 (A.76), 29 (A.98), 61 (A.206), 62 (A.210), 70 (A.234), 70 (A 235), 72 (A.244), 87 (A.296), 120 (A.414)
Anaesthesia, general: epidural, 182 (A.631)
Anaesthesia, general: intubation, 130 (A.445), 130 (A.446)
Anaesthesia, Inhalation, 26 (A.90)
Anaesthesia, inhalation, 99 (A 338)
Anaesthesia, intubating conditions: Infants, children, 139 (A 477)
Anaesthesia, Intubation, 22 (A.77)
Anaesthesia, low flow, 18 (A.61)
Anaesthesia, obstetric, 150 (A.512), 151 (A.519)
Anaesthesia, outpatient, 10 (A.34), 15 (A.50), , 15 (A.52), 16 (A 55)
Anaesthesia, paediatric, 142 (A.486)
Anaesthesia, regional, 16 (A 55), 109 (A 372)
Anaesthesia, retrobulbar, 105 (A 360)
Anaesthesia, spinal, 107 (A 366), 107 (A.367), 115 (A 396), 174 (A.604)
Anaesthesia, spinal: bupivacaine, 115 (A 395)
Anaesthesia, spinal: bupivacaine, mepivacaine, prilocaine, 115 (A.394)
Anaesthesia, sub-Tenon, 105 (A.360)
Anaesthesia, target controlled system, 100 (A 340)
Anaesthesia, technique, 22 (A 77)
Anaesthesia, tracheal, 22 (A.77)
Anaesthethics, local, 16 (A 55), 109 (A.373), 117 (A.401), 149 (A 510)
Anaesthetic concentration, rapid change, 52 (A 176)
Anaesthetic depth, 40 (A.137), 97 (A.332)
Anaesthetic equipment, 20 (A.69)
Anaesthetic gas, xenon, nitrous oxide, 137 (A 469)
Anaesthetic gases, xenon, halothane, 90 (A 306)
Anaesthetic induction, 58 (A.197)
Anaesthetic morbidity, 9 (A 31)
Anaesthetic record keeping, 6 (A.19)
Anaesthetic technique, caudal, 174 (A.603)
Anaesthetic technique, combined epidural-general, 91 (A 310)
Anaesthetic technique, epidural, 179 (A 621)
Anaesthetic technique, epidural, 174 (A 606), 175 (A.607)
Anaesthetic technique, extradural, 151 (A.519)
Anaesthetic technique, general, 91 (A.310)
Anaesthetic technique, interescalene brachial plexus block, 108 (A 370)
Anaesthetic technique, laryngoscopy, 23 (A 81)
Anaesthetic technique, laryngoscopy, 40 (A.135)
Anaesthetic technique, regional, 114 (A 392)
Anaesthetic technique, regional: ankle block, 173 (A 600)
Anaesthetic technique, regional. brachial plexus, 114 (A 391), 172 (A 599)
Anaesthetic technique, regional. intravenous, 110 (A.376)
Anaesthetic technique, subarachnoid, 119 (A.408)
Anaesthetic technique. combined spinal-epidural, spinal, 153 (A.525)
Anaesthetic techniques, I.v. infusion, 35 (A 120)
Anaesthetic, volatile: desflurane, 11 (A 39)
Anaesthetics, 89 (A.303), 138 (A 474)
Anaesthetics, gases xenon, nitrous oxide, 137 (A 470)
Anaesthetics, I.v.: fentanyl, 36 (A 123)
Anaesthetics, I.v.: propofol, 10 (A.36), 11 (A.38), 12 (A.42), 15 (A 51), 15 (A.53), 16 (A.56), 29 (A.99), 35 (A.120), 97 (A.330), 132 (A.451), 137 (A.470), 150 (A.515), 174 (A.606), 175 (A.607)
Anaesthetics, i.v.: remifentanil, 12 (A.42), 36 (A 123)
Anaesthetics, I.v.: target controlled infusions, 12 (A 42)
Anaesthetics, i.v.: thiopental, 150 (A.515)
Anaesthetics, inhalational: isoflurane, 88 (A.302)
Anaesthetics, intravenous, 18 (A.62), 34 (A.116), 36 (A 124), 184 (A 298)
Anaesthetics, local: bupivacaine, 144 (A.494), 149 (A.511), 153 (A.525), 171 (A 594), 173 (A.601)
Anaesthetics, local: lidocaine, 110 (A.376)
Anaesthetics, local: lidocaine, bupivacaine, 114 (A.391)
Anaesthetics, propofol, 13 (A.43)
Anaesthetics, remifentanil, 13 (A.43)
Anaesthetics, volatile, 25 (A.85), 26 (A.88), 27 (A 91), 63 (A.213)
Anaesthetics, volatile, 18 (A.62), 34 (A 116), 136 (A 465)
Anaesthetics, volatile: desflurane, 46 (A.156), 65 (A.219)
Anaesthetics, volatile: desflurane, 36 (A.123), 134 (A 457)
Anaesthetics, volatile: desflurane, isoflurane, 30 (A 101)
Anaesthetics, volatile: halothane, 88 (A.300)
Anaesthetics, volatile: isoflurane, 11 (A.39), 15 (A.53), 38 (A 131), 135 (A.462)
Anaesthetics, volatile: isoflurane, desflurane, sevoflurane), 27 (A.93), 28 (A.95), 28 (A.97)
Anaesthetics, volatile: Isoflurane45 (A.153)

Anaesthetics, volatile: sevoflurane, 10 (A.36), 11 (A 38), 15 (A.51), 15 (A 53), 16 (A 56), 29 (A.99), 37 (A.127), 37 (A 128), 38 (A 129), 40 (A.135)
Anaesthetics, enflurane, isoflurane, halothane, 63 (A.213)
Analgesia, 112 (A.382), 125 (A.430), 138 (A 472), 149 (A.510), 153 (A.526), 168 (A.583), 170 (A.588), 180 (A.624), 181 (A.628)
Analgesia, epidural: ketamine, 173 (A.602)
Analgesia, epidural: morphine, 173 (A 602)
Analgesia, obstetric, 149 (A.511), 153 (A.525)
Analgesia, patient-controlled: epidural, 179 (A 620)
Analgesia, patient-controlled, 150 (A.512), 178 (A.618), 179 (A.621), 180 (A.623)
Analgesia, postoperative, 174 (A.603)
Analgesic, extradural: fentanyl, 150 (A 512)
Analgesic, intravenous: morphine, 150 (A.512)
Analgesic techniques, 170 (A 592)
Analgesic techniques, extradural, 149 (A 511)
Analgesics, clonidine, 38 (A 129)
Analgesics, fentanyl, 97 (A.330)
Analgesics, fentanyl, tramadol, 96 (A 329)
Analgesics, morphine, 168 (A.580), 175 (A.608)
Analgesics, opioid. fentanyl, 89 (A.303), 153 (A.525)
Analgesics, opioid morphine, 171 (A.594), 174 (A.606), 175 (A.607), 183 (A.637)
Analgesics, opioid: morphine, tramadol, 178 (A.618)
Analgesics, pethidine, 179 (A.620)
Analgesics, pethidine, meperidine, 179 (A.621)
Analgesics, tramadol, 168 (A 580)
Analgosedation, 184 (A.639)
Angioplasty, 119 (A.410)
Ankle-brachial pressure index, 59 (A.199)
Antagonism, 123 (A 422)
Antagonist, naloxone, 174 (A.606)
Anterior approach, 111 (A.379)
Anti-edema effects, 125 (A.428)
Anti-inflammatory effects, 125 (A.428)
Antiemetics, ondansetron, cyclizine, 134 (A.459)
Antihistaminic, 133 (A.455)
Antinociception, 125 (A.428), 126 (A 433)
Antioxidant enzymes, 64 (A.214)
Anxiety, 47 (A.161), 133 (A.454)
Anxiolysis sedation, patient-maintained, 17 (A 58)
Aortic dissection, 164 (A.567)
Aortic surgery, 9 (A.30), 31 (A.106)
Approximate entropy, 97 (A.332)
Aprotinin, 80 (A.270), 80 (A.273), 81 (A.274), 81 (A.275)
Aprotinin administration, 80 (A.271)
ARDS, 71 (A 240), 184 (A 242), 73 (A.248), 74 (A.249), 78 (A.263), 161 (A 556)
Argon, 52 (A.178)
Arrhythmia, 66 (A 222)
Arterial catheter, 158 (A.544)
Arterial ketone bodies, 156 (A 534)
Arteries, 54 (A.185), 83 (A.282)
Arteries, aorta, 59 (A.200)
Arteries, aorta, 88 (A.300)
Arthritis, 125 (A.428)
Aspiration, 20 (A 67), 20 (A.68), 165 (A.571)
Aspiration pneumonitis, 162 (A.558)
Aspirin, 106 (A 361)
Assessment, 44 (A 149)
Atelectasis, 70 (A.235)
ATP depletion, 155 (A 533)
Atracurium, 122 (A.420), 123 (A 423)
AudioEP, 37 (A.126)
Audit, 5 (A.18), 140 (A.478)
Autologous blood transfusion, 79 (A.269), 95 (A.323), 89 (A 304)
Automated tonometry, 53 (A.179), 53 (A.181)
Autonomic nervous system, 61 (A 206)
Autoregulation, 62 (A.208), 98 (A.336), 103 (A 351)
Autotransfusion, 79 (A.268)
AVDL, 102 (A 349)
Axillary block, 108 (A.369), 144 (A.493)

B-mode echography, 160 (A 553)
Bacteria, 158 (A 543)
Bacterial clearance, 155 (A.531)
Bacterial infections, 158 (A.543)
Bacterial killing, 154 (A.527)
Balanced anaesthesia, 36 (A.122)
Bariatric surgery, 70 (A.237)
Barotrauma, 73 (A 247)
BIS, 38 (A 130), 40 (A.136), 96 (A.327)
Bispectral, 39 (A 132), 39 (A.133)
Bispectral index, 37 (A.125), 37 (A.126), 40 (A 137), 95 (A 325)
Bleeding, 68 (A.230), 80 (A 273)
Bleeding time, 85 (A.290)
Blood, 50 (A.170), 86 (A 292)
Blood, artificial oxygen carrier, 81 (A.276)
Blood, circulation, 103 (A 354)
Blood coagulation, 84 (A.285)
Blood flow, 99 (A.337), 155 (A.532)
Blood flow, coronary, 55 (A.186)
Blood-gas monitors, 49 (A.168)
Blood, haemodilution, 84 (A.285)
Blood loss, 80 (A.271), 83 (A 280)
Blood pressure monitoring, 142 (A.485)
Blood saving techniques, 95 (A.324)
Blood transfusion, 49 (A.168), 81 (A.276), 83 (A.280)
Blood transfusion, autologous, 82 (A.279), 84 (A.287)
Blunt trauma, 166 (A 576)
Body temperature, 8 (A.26)
Brachial plexus anaesthesia, 108 (A.369)
Brachytherapy, 141 (A.483)
Bradykinin, 86 (A.293)
Brain, 98 (A.333)
Brain, blood flow, 98 (A.336)
Brain contusion, 101 (A.343)
Brain injury, 103 (A 352)
Brain map, 100 (A.342)
Brain, perfusion, 56 (A.190), 56 (A.191)
Brain spectroscopy, 41 (A.138)
Brain tissue oxygenation, 102 (A.348)
Brain tumours, 99 (A.339)
Brainstem, 125 (A 431)
Breathing pattern, 71 (A.238)
Bronchoconstriction 74 (A.251)
Bupivacaine, 105 (A.358), 110 (A.378), 112 (A.385), 113 (A.388), 118 (A.407), 141 (A.482), 144 (A.494), 171 (A 595)

C4d and Bb fragments, 89 (A 304)
C7E3, 49 (A.169)
C7E3-fab, 42 (A.143)
C-Fos immunohistochemistry, 167 (A 577)
Ca^{2+} influx, 65 (A.221)
CABG surgery, 55 (A.187), 55 (A.189), 78 (A.265), 81 (A.275), 160 (A.552)
Cadaver donors, 101 (A.343)
Caesarean section, 151 (A.516)
Calcium, 104 (A 353)
Calcium channel blocker, 114 (A.393), 181 (A.628)
Cancellation, 44 (A.149)
Candida spp , 159 (A.547)
Capnography, 4848 (A.165)
Carbamazepine, 128 (A.440)
Carbon dioxide, 52 (A 178)
Carbon dioxide absorbers, 25 (A.85), 26 (A.88), 27 (A.91)
Carbon dioxide analysis, 49 (A 166)
Carbon dioxide elimination, 24 (A 83)
Carbon dioxide, end tidal, 48 (A.164), 146 (A.499)
Carbon dioxide reactivity, 68 (A.229)
Carbon monoxide, 25 (A.86), 25 (A.87), 26 (A.88), 26 (A.89)
Carboxyhaemoglobin, 25 (A 87)
Cardiac, 31 (A.105)
Cardiac anaesthesia, 79 (A 268)
Cardiac arrest, 166 (A.574)
Cardiac index, 185 (A 345)

BRITISH JOURNAL OF ANAESTHESIA

VOLUME 80, No.1 JANUARY 1998

EDITORIAL I

75 years ago

In 1998, the *British Journal of Anaesthesia* celebrates its 75th birthday. The first issue was published in July 1923. It was followed by a second issue in October of that year, and two more in 1924; together they became volume 1 of this international journal. The first editor, from 1923–1928, was Hyman Morris Cohen, a general practitioner and anaesthetist in Manchester. Born in New York on Christmas Day, 1875, Dr Cohen underwent military training and then studied medicine at Harvard University.[1] On graduating in 1896, he served as a Surgeon Lieutenant in the Philippines, where he studied both Spanish and the native language, and compiled an English–Spanish Visayan dictionary.[2] When he returned to New York in 1904, he married Etta Rothband, a Manchunian lady. Realizing that he too had relatives in Manchester, in 1913 Cohen resigned his commission from the military and the couple came to live in the city. Somewhat surprisingly, his medical qualification was not recognized in Great Britain and so without hesitation, Cohen retrained at St Bartholomew's Hospital Medical School, London. Here he is thought first to have come under the influence of the anaesthetist, H. Edmund Boyle, who encouraged Cohen to take up the specialty. On his British graduation in 1916 at the age of 40 yr, Dr Cohen began medical practice in Withington, Manchester and was appointed honorary anaesthetist at the St Mary's Hospitals, then the name of the Manchester teaching hospitals. The idea of a journal devoted to anaesthesia was probably conceived by Cohen, Boyle and another Manchester anaesthetist, S. R. Wilson. They arranged for guarantors and for a Manchester firm of printers and publishers, Messrs. Sherratt and Hughes, to publish the journal. This firm continued to produce the journal for the next 52 yr. But the *British Journal of Anaesthesia* failed by one year to be the first anaesthetic journal in the world; *Current Researches* (now *Anesthesia and Analgesia*) was launched in the USA in 1922.

Because of ill health, Dr Cohen retired as editor of the journal in 1928, and died from heart failure while driving through the Derbyshire countryside, in 1929.[2] Dr Wilson died in the same year. Dr Joseph Blomfield, a consulting anaesthetist at St George's Hospital, London, became the second editor. Dr Blomfield was a past president of the Royal Society of Medicine, Anaesthetic Section; he had been chairman of the anaesthetic committee of the Medical Research Council and was a founder member and a future president of the Association of Anaesthetists. Dr Blomfield was to remain editor until his death almost 20 yr later in 1948.[3] By this time, after the stringencies of the Second World War, the journal was only published infrequently; each volume was thin and the quality of production was inferior. The next co-editors, E. Falkner Hill of Manchester and T. Cecil Gray of Liverpool (1948–1958), were to begin the transformation of the *British Journal of Anaesthesia* into the form we know today. The continued development of the journal has been supported vigorously by its subsequent editors: T. C. Gray, by himself (1958–1963); J. E. Riding (1963–1973); A. A. Spence (1973–1983); W. Fitch (1983–1987); and G. Smith (1987–1997).

Volume 1 of the journal now makes interesting, albeit light, reading; it is a marked contrast from its present day descendant. But nevertheless the anaesthetists of the 1920s could teach us much about clinical practice; their technical and observational skills were, probably of necessity, greater than many of us possess today. In this issue, Drury describes anaesthetic practice in that decade in detail.[4] Pharmacological enthusiasts were as commonplace as they are now, but perhaps more adventurous. There are articles in volume 1 discussing potential new inhalation agents, such as that by Langton Hewer on acetylene,[5] which was a popular agent in Germany at the end of the last century. Langton Hewer noted that this gas was odourless (although many anaesthetists thought that acetylene, in common with ethylene, smelt of garlic).[4] Acetylene produced good muscle relaxation; rapid recovery could be relied upon and it was thought to be free from "side-effects". Its explosive properties caused less concern in the days when diathermy was only just being introduced. But it is interesting that rapid induction and awakening were as attractive features of an inhalation agent then as they are today. Concern was expressed about the difficulty in preventing postoperative nausea and vomiting, which were more frequent in those days when ether, chloroform and ethyl chloride were the main potent inhalation agents in use. No satisfactory drug treatment was available. Much discussion was continuing as to whether nitrous oxide alone was a satisfactory agent. It was appreciated that, if surgical anaesthesia was to be obtained, cyanosis was almost an inevitable accompaniment of such a technique, but to many anaesthetists, this did not cause the concern it would today.[6]

Details of local anaesthetic techniques are found in volume 1. Sacral extradural anaesthesia is described by Blomfield (the future editor).[7] Convulsions were a well recognized side effect of this technique. But it was not considered that these might be caused by the toxic effect of the local anaesthetic agent, which was usually procaine. It was generally agreed, however, that the majority of patients survived this experience without any long-term sequelae! The beneficial effect of alkalinization of local anaesthetics on the intensity of block was also appreciated at that time, as was the need to use aseptic techniques to avoid irreversible neurological complications: a topic in which there has recently been much renewed interest.[8]

Anaesthetists in 1923–1924 were concerned to keep patients warm, especially during prolonged surgery, and possibly made more effort in this respect (by wrapping all four limbs in cotton wool) than we do now. "Exposure" was thought to be responsible in part for postoperative pneumonia.[9] Actually, perioperative mortality is given serious consideration in this first volume. The causes are similar to those today: postoperative pneumonia; massive haemorrhage; and cardiac arrhythmias. But the incidence was greater, in the order of 0.3%. It was thought that anaesthetic deaths were much more common in the public than in the private sector, and this was explained by the greater skill of those practising in private hospitals.[9]

A. G. Levy, a London physician who was an early exponent of internal cardiac massage, exhorts anaesthetists to attempt massage through the left pleural cavity if cardiac arrest occurs during anaesthesia. Even today, there may be a reluctance to make this vital decision in a life-threatening situation. Levy warned that cardiac massage from below the diaphragm is insufficient.[10] He was later to stress the risk of cardiac arrest during chloroform anaesthesia.[4]

Tracheal tubes were just beginning to be experimented with in 1923; perhaps this is one of the biggest contrasts from present day practice.[6 11] They were used to protect the airway when it was threatened by malignant disease or a thyroid goitre; such tubes were not developed to allow artificial ventilation. The lack of mention of a neuromuscular blocking drug, or even the need for one, is almost incredible. But undoubtedly it was appreciated at that time that straining during an abdominal procedure not only caused difficulties for the surgeon, but also increased postoperative morbidity, especially in obese patients or those with pulmonary disease. Equipment enthusiasts give descriptions of improved ether masks,[12] and discuss the questionable benefits of warming ether before administration; much doubt was expressed by Shipway about its validity.[13]

Not surprisingly with an American editor, there is a significant American contribution to the first volume; even in 1923, this was an international journal. Various remedies for treating pain during childbirth are presented from the New York lying-in hospital; most are given by the rectal route and consist of mixtures of opioids, hyoscine, ether and today's panacea, magnesium sulphate.[14] One author of these articles was a founder and first president of the American Association of Anesthesiologists, James Gwathmey. Indeed, administration of drugs or fluids by the i.v. route is scarcely mentioned, another marked contrast from present day practice.

It is heartening that some anaesthetists, even in 1923, were acutely aware of the need to teach undergraduates about anaesthesia, for a healthy recruitment to our specialty. Wesley Bourne of McGill University, Canada, describes in detail the teaching of anaesthesia to his final year medical students[15]; oh, that we had the same opportunities today! The students had anaesthesia demonstrated first in the animal laboratory, where they were taught to make basic physiological estimations, using for instance, a pneumograph to measure respiratory rate. Non-invasive arterial pressure was measured in the hind leg of dogs receiving the inhalation anaesthetics of the day at varying concentrations. Only after this experience were students allowed to enter the operating room, where they were taught the need for detailed recording of physiological variables during anaesthesia. But there is no mention of undergraduate students being examined in anaesthesia or being required to administer a minimum number of anaesthetics. McGill University has often led the way in teaching medical undergraduates: how fortunate those students were to receive such individual tuition.

The historical reviews in volume 1 are, perhaps, of the greatest interest; surely all anaesthetists will be curious about the lives of Joseph Clover and John Snow. Clover's reserved character is succinctly described by D. W. Buxton; the author believed that it was this facet, together with poor health, that prevented Clover from being a successful surgeon![16] A discussion of anaesthesia from distant times to date was given by the eminent historian, Sir D'Arcy Power (who later wrote H. M. Cohen's obituary)[2]: he points out that, in the middle ages, perioperative nausea and vomiting were even common amongst surgeons![17]

Interestingly abstracts, the loathing of many contemporary editors, appeared in significant numbers, although not just from presentations at learned societies, but also as summaries of original articles from other scientific journals; copyright legislation must not have been the threat it is today. Notices and letters concerning political matters were also common; in fact, in those days, this journal resembled an official journal of an anaesthetic society, in a way that would now be inappropriate! The need for an official association of anaesthetists is mentioned in the opening editorial.[18] Not only the Scottish Society of Anaesthetists (second to the Royal Society of Medicine, Anaesthetic Section as the oldest British anaesthetic society),[19] but also the Canadian, and American and Pacific Coast Anaesthetists, had reports on their recent meetings. Book reviews were scattered through the text but, in addition, bibliographies of recent anaesthetic literature were supplied. One unnamed author argues, in a notice, of the need for a postgraduate diploma in anaesthesia. A minimum of 6 months is thought necessary for training: 3 months at any specified hospital, followed by 3 months spent at one teaching hospital by all candidates. The University of Cambridge is recommended.

Volume 1 makes easy reading because the articles are short and anecdotal. The use of references is uncommon; statistical analysis does not exist and thus the flow of words is uninterrupted. When I borrowed it from the Liverpool Medical Institution, volume 1 had not been lent out for over 25 yr; the last date due for return was May 1, 1971. May I recommend that readers browse through it again; as well as being of enormous interest, it has many salutary lessons for us to learn.

In his opening editorial of volume 1,[18] H. M. Cohen said: "it is hoped to be able to keep abreast of the times in all that appertains to anaesthesia, and to reflect the progress our speciality (sic) is making everywhere". As the ninth editor-in-chief of this international journal, such is my task for the next 5 yr.

EDITORIAL II

BJA citation classics 1945–1992

It is perhaps a common fault of the British that they spend too long looking at their distinguished past rather than planning for an innovative future. Nevertheless, 1998 marks the 75th anniversary of publication of the *British Journal of Anaesthesia* and the editorial board asked the Institute for Scientific Information (ISI) to undertake a search for the 50 most cited publications from 1945 until the end of 1992. These citation classics are listed in rank order at the end of this editorial (51 publications are cited as there was a joint 50th position).

There is considerable debate about the value of citation indices. The simple assumption is that citations reflect the use of the document and its impact on the specialty. Furthermore, they are used increasingly to assess scientific performance and even as an aid to determining scientific policy. There is little doubt that authors are increasingly aware of the "ratings" of the anaesthetic journals when submitting manuscripts. Sceptics argue that citation counts provide no estimate of the quality of a publication, emphasize that there is no satisfactory theory to explain citation indices and doubt the evaluations based on them. In spite of these opposing views, I believe that the *BJA* citation classics provide a fascinating insight into the development of anaesthetic practice since 1945.

Some of my preconceived ideas about the probable content of the list had to be revised. I was surprised by the international nature of the contributions at a time when the journal did not seek deliberately a global role. Citation classics originated from the USA, Canada, Australia, South Africa, Germany, Denmark, Sweden, Finland and Israel: in total approximately one-third of manuscripts. I also expected that there would be many review articles in the citation classics. However, basic research articles predominated, although there were reviews on: the pharmacokinetics of local anaesthetic drugs (No. 9); solubility coefficients for inhaled anaesthetics (No. 14); clinical assessment of neuromuscular transmission (No. 38); benzodiazepines (No.42); and the physiology of cerebral blood flow (No. 49). Several citation classics describe the introduction of important new drugs: halothane in 1956 (No. 4); pancuronium in 1967 (No. 33); propranolol in 1967 (No. 27); diazepam in 1970 (Nos 16 and 42); Althesin in 1971 (No. 8); and atracurium in 1981 (No. 6 and 12). The importance of unpredictable adverse responses to commonly used anaesthetic agents is highlighted by the classic articles on malignant hyperthermia (Nos 2, 11 and 13), histamine release after i.v. drugs (Nos 19, 25 and 26) and nitroprusside metabolism (No. 30).

Nearly 25% of the articles describe investigations into respiratory and cardiovascular aspects of anaesthesia. This probably reflects the importance of these subjects in past decades, but it is also coincident with the observation that citation classics occur most commonly 20–25 yr after publication. It is interesting, therefore, to examine those classics which have achieved recognition over a prolonged period of time or very quickly.

Three classics were published more than 35 yr before the end of the search, that is before 1957 (Nos 4, 5 and 47). These articles describe the clinical evaluation of halothane (1956), elimination of rebreathing in various semi-closed anaesthetic systems (1954) and EEG changes produced by thiopental (1951), respectively. The citation search revealed that all three articles were quoted in 1992, and Mapleson's paper on five occasions. Indeed, the sustained contribution of Mapleson to anaesthetic research is remarkable; he last published in this journal in 1997. At the other end of the time scale, six articles achieved classic status within 12 yr of publication, 1980 or later. Two describe the pharmacology of atracurium (Nos 6 and 12) and two are concerned with the efficacy of extradural morphine (No. 7) and its complications (No. 3). The remainder are a review of the monitoring of neuromuscular transmission (No. 38) and the pharmacokinetics of fentanyl and alfentanil (No. 48). There are some obvious similarities between the old and new classics: clinical evaluation of new agents, description of the elimination of anaesthetic drugs (gases) and the novel central nervous system effects of existing drugs. The importance of extradural opioids in modern practice is mirrored by the rapid achievement of classic status of the contributions from Sweden (No. 3) and Israel (No. 7).

This list defines the top 50 cited publications at the end of 1992 and so must be considered a "snapshot" of the *BJA* literature. Changes are inevitable, and the search showed that some classics had not been cited in the past 2 yr. It was notable, however, that many publications in the top half of the list were cited frequently in 1992 (Nos 1, 3, 4, 5, 8, 9, 14, 16 and 17) and so are likely to remain classics for some time.

It was an enjoyable task to read all the manuscripts. I was struck not only by the marked changes in anaesthetic and surgical practice, but also in the design and conduct of clinical research. Gastric surgery was commonplace and used frequently as a model for upper abdominal procedures. In one study, 90% of patients were smokers (No. 36). Ethics Committees and informed consent were rarely mentioned, randomization and blinding often omitted, and when statistical analysis was undertaken it was unusual for the test to be described. Conversely, great emphasis was often placed on the accuracy and precision of the physiological measurements, and the number of patients studied was usually large (173 in No. 31 and 265 in No. 46). The articles were often lengthy, with a discussion that ranged freely around the subject and so allowed the development of further ideas. In contrast, Harrison succinctly described the successful use of dantrolene in malignant hyperthermia in five pigs in two pages (No. 13). It is probable that some of these classics would not survive rigorous assessment in 1998 and yet they represent the standard of the time, and their value to anaesthesia is beyond doubt.

The editor-in-chief has chosen 12 articles from the list of citation classics and one will be reproduced in each issue of the journal in 1998, followed by a short commentary on the importance of the work. The editorial board hope that this brief bout of nostalgia will be an interesting addition to the usual articles. The board will strive to continue to serve both readers and authors as we work towards the centenary in 2023.

CLINICAL INVESTIGATIONS

Comparison of continuous and intermittent administration of extradural bupivacaine for analgesia after lower abdominal surgery

L. A. DUNCAN, M. J. FRIED, A. LEE AND J. A. W. WILDSMITH

Summary

We have compared intermittent bolus and continuous infusion of extradural local anaesthetic for pain relief in a randomized, double-blind study of 48 patients who underwent major abdominal gynaecological surgery. Each patient received 5 ml of 0.375% bupivacaine hourly, either as a bolus over 5 min or as a constant infusion. Patients who received the intermittent administration technique maintained a more extensive sensory block, reported marginally better analgesia and had a lower requirement for rescue medication. The intermittent bolus technique was not associated with an increase in side effects. (*Br. J. Anaesth.* 1998; **80**: 7–10)

Keywords: analgesic techniques, extradural; anaesthetics local, bupivacaine; surgery, gynaecological

Extradural administration of local anaesthetic is now well established in the management of acute pain. Constant rate infusion from an electromechanical pump is generally used, mainly to minimize medical and nursing workload. In addition, there is a perception that constant infusion produces an unchanging block to maintain analgesia and minimize cardiovascular disturbance.[1] With constant infusions of local anaesthetic, sensory block has been shown to regress with time resulting in a requirement for supplementary analgesia,[2, 3] and even in the presence of an apparently effective extradural block there may be a need for additional medication (usually an opioid) in as many as 50% of patients.[4]

Intermittent injections of extradural local anaesthetic may provide more reliable analgesia than that obtained by continuous infusion,[5] but the lack of suitable pumps implied that this method could not be used widely. The development of devices which can deliver bolus injections at regular intervals has now made this method of administration practicable. This study was designed to compare constant infusion and intermittent injection of extradural bupivacaine after major gynaecological surgery.

Patients and methods

After obtaining approval from the area Ethics Committee and informed consent, we studied 48 ASA I, II or III patients. All were undergoing major gynaecological surgery via a lower abdominal incision and were premedicated with temazepam 10–30 mg, 1 h before operation. On arrival in the anaesthetic room a peripheral i.v. infusion of Hartmann's solution was commenced and an extradural catheter was inserted at a lower thoracic or upper lumbar spinal interspace. A test dose of 4 ml of 2% lidocaine was administered to exclude intravascular or intrathecal catheter placement and was followed by 16 ml of 2% lidocaine with epinephrine 1:200 000. General anaesthesia was induced with either thiopental 250–375 mg or propofol 100–200 mg i.v. and maintained by inhalation of either enflurane or isoflurane (1–2%) and 70% nitrous oxide in oxygen. Patients breathed spontaneously via a laryngeal mask or a tracheal tube, and succinylcholine 1 mg kg^{-1} was used to facilitate intubation if required.

At 1 h or skin closure, whichever occurred first, 0.5% bupivacaine 10 ml was injected extradurally. Patients were then allocated randomly to one of two postoperative extradural regimens. Every patient received 0.375% bupivacaine 5 ml hourly, either at a constant rate infusion (control group) or as an hourly bolus delivered at 1 ml min^{-1} (study group). A Medfusion 2001 syringe pump (Medex Medical) was used in all patients and was programmed by an anaesthetist who was not one of the investigators, all of whom were unaware of the mode of administration until the end of the study. All patients received i.v. patient-controlled analgesia from an Abbott Lifecare PCA system set to deliver a 1-mg bolus doses of morphine with a lockout time of 5 min.

As soon as the patient was able to co-operate after recovery of consciousness, the upper and lower levels of block to pinprick and the degree of motor block (Bromage scale) in the legs were assessed, together with pain (10-cm visual analogue scale (VAS)) at rest, on coughing after deep inspiration and on moving from the supine to the sitting position. These assessments were repeated 2, 4, 6, 9, 12, 21 and 24 h after surgery. At 4, 9 and 24 h, cumulative morphine consumption was recorded and patients were asked to rate pain control to date using a four-point verbal rating scale (VRS: 1 = poor, 2 = fair, 3 = good, 4 = excellent). Routine measurements of heart rate, arterial pressure, ventilatory frequency (hourly) and volume of extradural solution infused were carried

out by the nursing staff according to normal ward practice.

Comparisons between groups were made using chi-square and Mann–Whitney with Bonferroni correction tests, as appropriate.

Results

Eight patients were excluded from the study, two as a result of technical problems with either the extradural or the infusion pump, and six as a result of design violations by the ward nursing staff. In patients who completed the study, there were minimal differences between the two groups in patient characteristics, level of extradural catheter insertion, type of incision and duration of surgery (table 1). At the first assessment after surgery there were no differences between groups in the degree of sensory or motor block, but those patients who received intermittent boluses had, as a group, more extensive sensory (pinprick) blocks thereafter. The difference was significant at 2, 4, 6, 9 and 24 h (fig. 1), but there was no difference in the degree of motor block at any time (fig. 2).

An obviously unilateral block developed in two patients in the intermittent bolus group and five in the continuous infusion group. Three patients in the intermittent group (including one with a unilateral block) received a single bolus injection of 0.5% bupivacaine 5 ml because of poor analgesia. In the continuous group, six such patients (including one with unilateral block) required a total of 19 single bolus injections for breakthrough pain (table 2). Unilateral blocks were treated only if pain relief was poor. Mean bupivacaine consumption for the 24-h study period was 456 mg in the intermittent bolus group and 473 mg in the infusion group ($P < 0.001$). Morphine consumption tended to be lower in the group receiving intermittent bolus administration, but the difference was not significant (table 2).

Both VRS and VAS results (figs 3–5) suggested that the quality of analgesia was somewhat better in the intermittent bolus group. If a VRS score of good or excellent is taken as satisfactory then 74%, 89% and 84% of patients in the intermittent group had acceptable pain relief at 4, 9 and 24 h compared with 55%, 71% and 67% of patients in the continuous group. The difference between the groups in VRS was significant at 24 h ($P = 0.05$). VAS results at rest and during movement were significantly better in the intermittent group at 4 and 6 h, but there was no difference in pain during coughing at any time (figs 4 and 5).

There were no differences in cardiovascular variables between the groups, and there were no episodes of hypotension requiring treatment in any patient.

Discussion

Extradural administration of local anaesthetic drugs provides useful analgesia after surgery, but supplementary analgesia (usually an opioid) is often required.[6] This study confirms these findings, with patients in both groups reporting low pain scores while consuming moderate amounts of morphine. Median VAS pain scores were less than 30 mm in the intermittent group at all times and, although higher, were still satisfactory in the continuous group. Patient satisfaction was assessed using a four-point VRS and was greater in the intermittent bolus group (fig. 3).

Previous investigators have suggested that continuous extradural local anaesthetic infusion is associated with less hypotension, less motor block and uninterrupted analgesia compared with intermittent bolus injection.[7] Similar results have been obtained when extradural block was used to provide analgesia in labour.[8] However, in those studies the bolus injection was administered only when the patient had developed pain and requested relief. The advantage of constant infusion techniques is that the level of block does not change acutely and the aim of this study was to see if a similarly constant block could be produced by intermittent, but regular, bolus injection. In a previous study, Scott, Schweitzer and Thorn found that this method of extradural local anaesthetic injection produced more predictable analgesia than continuous infusion without any increase in side effects.[5] However, the injections were made by nursing staff and it was not always possible to give them frequently enough to maintain analgesia.

In this study a modern electromechanical pump was used to deliver regular hourly bolus doses of bupivacaine and the findings confirm those of the earlier study. Heart rate and arterial pressure were recorded hourly by the ward staff and there was no cause for concern with either intermittent or continuous injection. However, these were relatively healthy patients who were assessed by routine clinical methods after straightforward lower abdominal surgery. A more definitive comparison of the cardiovascular effects of the two modes of extradural administration is in progress in older patients undergoing upper abdominal surgery.

In both groups the sensory level of analgesia regressed progressively during the first 6 h after operation and then remained relatively stable, a feature of continuous extradural block noted previously.[2 9 10] The initial regression has been ascribed to either tachyphylaxis or changes in local blood flow altering the uptake of local anaesthetic, but it is most likely that this represents regression of the larger bolus doses used for surgery. The block remained more extensive in the intermittent group and this is consistent with the latter interpretation.

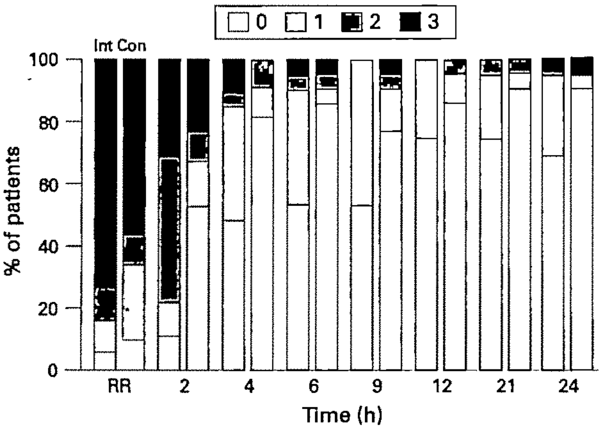

Figure 2 Degree of motor block (Bromage scale) in the intermittent bolus (Int.) and continuous infusion (Con.) groups. Most dense block recorded when motor block differed between legs. RR = Recovery room.

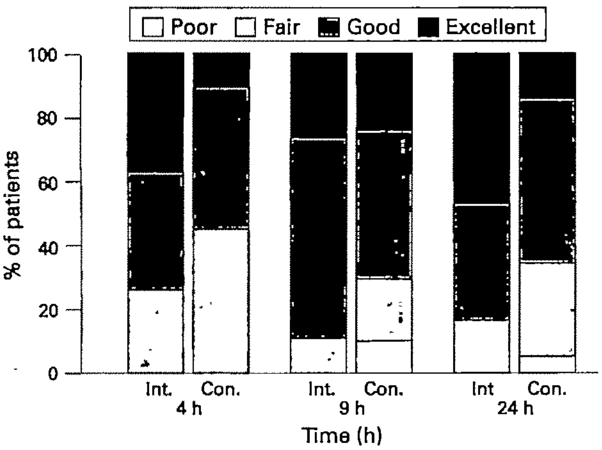

Figure 3 Verbal rating score (VRS) of overall satisfaction with pain control in the intermittent bolus (Int.) and continuous infusion (Con.) groups.

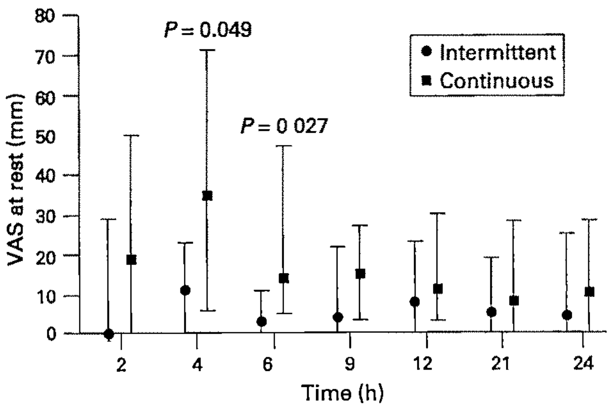

Figure 4 Visual analogue scores (VAS) at rest (median, interquartile range) in the intermittent bolus and continuous infusion groups.

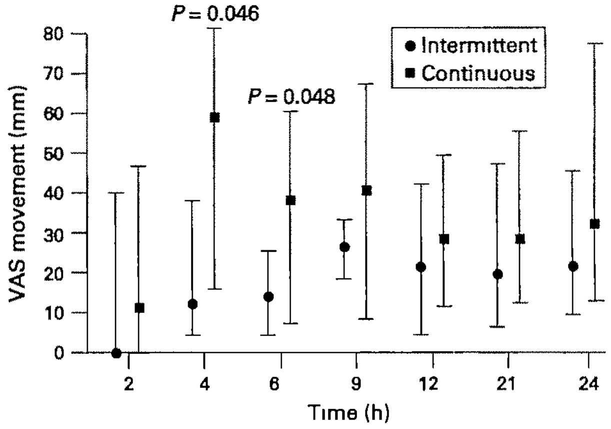

Figure 5 Visual analogue scores (VAS) on movement (median, interquartile range) in the intermittent bolus and continuous infusion groups

The faster bolus injection may create a higher pressure in the extradural space and cause the solution to spread further. In contrast, a low volume continuous infusion may be less likely to spread far from the extradural catheter, so that regression of block is more likely.

All patients in the study received opioid analgesia in addition to extradural local anaesthetic. This was by i.v. PCA, although there may be advantage in administering the opioid extradurally with the local anaesthetic.[11] One of the advantages claimed for mixtures is that reduced local anaesthetic dosage decreases the incidence of lower limb motor block. However, lower limb paralysis was minimal by 4 h in both groups (fig. 2), perhaps reflecting the level of catheter insertion as much as local anaesthetic dose. Motor block may be more of a problem with continuous lumbar extradural block after lower limb surgery.

The addition of opioid to an extradural infusion also carries the risk of producing profound respiratory depression and the underlying theme of this project was to see if modification of the technique of administration produces better quality analgesia with local anaesthetic alone, and so minimize the need for opioid supplementation. PCA with morphine was used primarily to provide another method of comparing the effectiveness of the two techniques. The supervision of both extradural and PCA infusion pumps caused no practical problems, although it may be difficult to provide both in the routine clinical setting. This is one of the reasons for trying to minimize opioid requirements by developing the method of extradural injection.

It may seem surprising that there was little difference between the groups in morphine consumption, despite lower pain scores and better patient satisfaction with the intermittent technique, but there are two possible explanations. First, a recent study has cast doubt on the reliability of PCA as an assessment technique, noting that patients use it for reasons other than pain relief.[12] Second, the aim was to provide good analgesia for all patients in the study. As a result, several patients in pain, despite the use of PCA, received supplementary bolus injections of bupivacaine from investigators who did not know which method was in use. Nineteen such injections were administered to those in the continuous group, in comparison with only three to the intermittent group and this almost certainly masked any potential increase in morphine requirement in the continuous group. An increased local anaesthetic requirement has also been shown when continuous infusion is compared with intermittent injection by patient-controlled extradural analgesia in labour.[13]

We conclude that regular, intermittent extradural administration of local anaesthetic provided better quality analgesia after surgery and reduced the need for supplementary medication compared with constant infusion of local anaesthetic. This study only compared two specific injection techniques and a wide range of combinations of volume, drug concentration and infusion rate is possible. However, the results suggest that a reappraisal of intermittent injection techniques for extradural analgesia using modern devices to ensure fixed time intervals of administration is merited. Variations in the volume, concentration and time interval of injection might reduce further the need for supplementary medication and for a separate PCA device.

Minimum local analgesic concentration of extradural bupivacaine increases with progression of labour

G. Capogna, D. Celleno, G. Lyons, M. Columb and P. Fusco

Summary

We have used the technique of double-blind sequential allocation to quantify the minimum local analgesic concentration (MLAC) of extradural bupivacaine for women in early (median cervical dilatation 2 cm) and late (median cervical dilatation 5 cm) labour. The first bolus was 20 ml of the bupivacaine test solution. The concentration was determined by the response of the previous woman to a higher or lower concentration of bupivacaine according to up and down sequential allocation. Efficacy was assessed using a 100-mm visual analogue pain score (VAPS). The test solution had to achieve a VAPS of 10 mm or less to be judged effective. In early labour, the MLAC of bupivacaine was 0.048% w/v (95% confidence intervals (CI) 0.037–0.058% w/v), and 0.140% w/v (95% CI 0.132–0.150% w/v) in the late group. The MLAC of bupivacaine in late labour was greater by a factor of 2.9 (95% CI 2.7–3.2) compared with the MLAC in early labour ($P < 0.0001$, 95% CI difference 0.08–0.11). We conclude that advancing labour requires an increased concentration of extradural bupivacaine for pain relief. (*Br. J. Anaesth.* 1998; **80**: 11–13)

Keywords: pregnancy; analgesia, obstetric; analgesic techniques, extradural, anaesthetics local, bupivacaine

Bupivacaine is used widely to provide extradural pain relief in labour in a wide range of doses, concentrations and volumes. The paucity of data on the dose–response relationships of extradural analgesics in labour has led to the development of a benchmark for extradural local anaesthetics, the minimum local analgesic concentration (MLAC). This is defined as the effective concentration in 50% of women in the first stage of labour (EC_{50}).[1]

The impact of advancing cervical dilatation on the MLAC has never been assessed, and we sought to take advantage of differing obstetric policies within a single maternity unit. Because one obstetric team discouraged extradural pain relief in early labour, two groups of women, one in early labour and one in late labour with minimal overlap with regard to cervical dilatation, were created. Our aim was to measure and compare the MLAC of bupivacaine at different stages of labour in these two groups of women.

Patients and methods

Our hospital Ethics Committee approved this double-blind sequential allocation study. After obtaining informed consent, we studied 61 women, ASA I or II, with singleton pregnancies and vertex presentation, requesting extradural pain relief in the first stage of labour. We excluded women who had received opioid or sedative drugs. Use of transcutaneous electrical nerve stimulators and Entonox before extradural request was not regarded as a need to exclude.

The extradural technique was standardized. I.v. Ringer's solution was infused via a forearm cannula. The extradural space was found, either at L2–3 or L3–4 interspace, in the sitting position. Loss of resistance to saline was used to identify the extradural space, limiting the injection to 2 ml in order to minimize dilution of local anaesthetic. The extradural catheter was advanced 3 cm into the space and then aspirated. For the purpose of the study, the test dose was omitted.

The first administration of bupivacaine was from a freshly prepared syringe containing 20 ml of test solution given over 5 min; bupivacaine was diluted with 0.9% w/v saline to achieve the desired concentration at room temperature.

We recruited two groups of 30 women each. Each group was comprised of women from a single obstetric team, one in early and one in late labour, creating two groups with different ranges of cervical dilatation at the time of extradural insertion. The diagnosis of labour was confirmed by the obstetric team before extradural request. Entry into the study required an initial visual analogue pain score (VAPS) greater than 30 mm.

The first woman in each group received 0.1% w/v bupivacaine, in common with the starting point of an earlier study.[2] Thereafter, the concentration of the test solution in each individual syringe was determined by the response of the previous patient to the higher or lower concentration in her test syringe, according to up and down sequential allocation. Maternal pulse, arterial pressure, frequency of contractions and fetal heart rate were monitored.

ASSESSMENT

Efficacy of the first dose was assessed using a 100-mm VAPS. The side presented to the woman in labour portrayed faces depicting happiness (0) to misery (100) in five stages. A movable cursor

Table 1 Patient characteristics (mean (SD)), median (interquartile range) or number). Women in late labour had greater dilatation of the cervix (P<0.0001) and higher initial visual analogue pain scores (VAPS) (P<0.0001) than those in early labour

	Early (n=30)	Late (n=30)
Age (yr) (mean (range))	28.2 (22–35)	29.3 (23–38)
Weight (kg)	75.5(6.53)	74 1(6.95)
Height (cm)	166.4(4.20)	168.3(4.95)
Gestation (weeks)	40 (40–41)	40 (40–41)
Nulliparous	23	25
Multiparous	7	5
Oxytocin	8	12
Cervix (cm)	2 (2–3)	5 (5–5)
Initial VAPS (cm)	68 (59–70)	90 (85–94)

provided a numerical selection on the rear of the scale. Observations were made at 0, 15, 30 and 60 min after injection of the first bolus containing study solution. Three outcomes were possible.

Effective

This required that the VAPS decreased to 10 mm or less at the height of contraction, within 60 min, and indicated the end of the study and directed a decrement of 0.01% w/v bupivacaine for the next woman.

Ineffective

This followed failure of the VAPS to reach 10 mm within 60 min of the test solution. If at 30 min the woman claimed satisfactory analgesia despite not reaching the VAPS target of 10 mm, the study period was extended to a possible maximum of 60 min. At 30 min, after failing to reach the VAPS target, rescue analgesia consisting of 0.25% w/v bupivacaine 12 ml was offered. After this, a reduction in VAPS to 10 mm or less indicated the end of the study and directed a 0.01% w/v bupivacaine increment for the next woman.

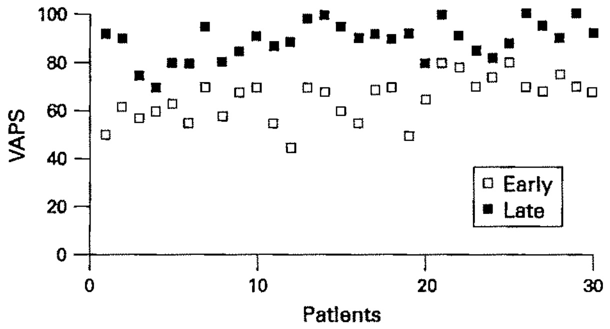

Figure 1 Visual analogue pain scores (VAPS) before extradural analgesia in the early and late groups. Median values (interquartile range) were significantly lower in the early labour group (68 (59–70) vs 90 (85–94); P<0.0001).

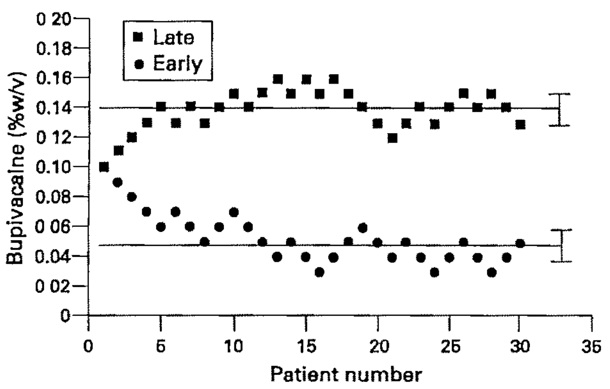

Figure 2 Minimum local anaesthetic concentration (MLAC) of bupivacaine in early and late labour, as determined by the technique of up–down sequential allocation. In the early labour group, the MLAC of bupivacaine was 0.048% w/v (95% CI 0.037–0.058% w/v) and in the late labour group, 0.141% w/v (95% CI 0.132–0.150% w/v) (P < 0.0001).

Repeat

Failure to achieve a VAPS of 10 mm after the rescue bolus implied a technical failure, and directed that the same concentration be repeated for the next woman.

For all women, age, weight, height, gestation, parity, cervical dilatation and use of oxytocin were recorded.

STATISTICAL ANALYSIS

Patient and obstetric data were collected and are presented as mean (SD) and median (interquartile range) as appropriate. The median effective concentration was estimated from the up–down sequences using the formula of Dixon and Massey which enabled MLAC with 95% confidence interval to be derived.[3] The data were also subjected to Wilcoxon and Litchfield probit regression analysis as a back-up sensitivity test. Further analyses included Student's t test, Mann–Whitney U test, Kolmogorov–Smirnoff test for Gaussian distribution and Fisher's exact test.[4 5] All analyses were carried out on two personal computers (Dell Dimension XPS P100c and Zenith Z-Star EX 486DX 50) using the following software: Microsoft Excel 6.0a for Windows, Statistical Package for the Social Sciences (SPSS) 6.1 for Windows, GraphPad Instat 2.05a for DOS and Pharmacologic Calculation System (PCS) 4.2 for DOS. Statistical significance was defined for an overall α error at the 0.05 level. All P values were two-sided.

Results

There were no significant differences in characteristics in the groups (table 1).

Women in late labour had greater cervical dilatation (median 5 (interquartile range 5–5) cm) than those in early labour (2 (2–3) cm) (P < 0.0001).

The first VAPS recorded in women in early labour (median 68) were significantly lower (P < 0.0001) than those recorded in late labour (median 90) (fig. 1).

One woman in late labour had unilateral pain that did not respond to the rescue bolus. This concentration was repeated for the next patient. The sequences of effective and ineffective analgesia are shown in figure 2.

The MLAC of bupivacaine in early labour was 0.048% w/v (95% CI 0.037–0.058% w/v) using the formula of Dixon and Massey, and 0.046% w/v (95% CI 0.038–0.056% w/v) by probit regression. The MLAC of bupivacaine in late labour were 0.141% w/v (95% CI 0.132–0.150% w/v) and 0.140% w/v (95% CI 0.132–0.149% w/v), respectively. This difference was significant (P < 0.0001, 95% CI difference 0.08–0.11). The MLAC of bupivacaine in late labour was significantly greater than that in early labour by a factor of 2.9 (95% CI 2.7–3.2).

Discussion

We have shown that the MLAC of bupivacaine increased with advancing labour. This implies that when low concentrations of local anaesthetic are used for extradural analgesia in order to achieve motor sparing and perhaps ambulation, the concentration may need to be increased as labour progresses to maintain satisfactory analgesia. Breen and colleagues reported that approximately 50% of women receiving an infusion of 0.04% w/v bupivacaine in combination with fentanyl 1.7 μg ml^{-1} and epinephrine 1.7 μg ml^{-1} went on to deliver without a change in regimen.[6]

The application of the two obstetric policies was not exact, and there was a minor degree of overlap with regard to cervical dilatation. One woman in late labour had a cervical dilatation of 3 cm; without this the two groups would have been distinct. The double difficulties posed by differing obstetric policies and consumer choice prevented randomization to the groups.

There was a significant difference in the two groups regarding the initial VAPS. This suggests that the obstetric policy was effectively applied to women in late labour who might otherwise have received extradural pain relief earlier.

The use of saline to detect loss of resistance implied that dilution of the test concentration of bupivacaine could have occurred within the extradural space. To minimize this, extradural injection of saline was reduced to a clinically insignificant volume. The alternative to saline would have been air. This was rejected because of a suggestion that pockets of air in the extradural space might obstruct the spread of local anaesthetic.[7]

The role of concentration of local anaesthetic in conduction block is in the production of differential nerve block.[8] The requirement for an increasing concentration as labour progresses prompts speculation that larger fibres are recruited as the cervix opens and the head descends. The term *visceral* is used to describe the pain of the contracting uterus and the dilating cervix, supplied by sympathetic afferent fibres, which characterizes the first stage of labour. As the presenting part distends and compresses pelvic structures during the second stage, the pain is described as *somatic.*[9] In reality the distinction between the two is not always clear cut, but it might be reasonable to speculate that at the earliest moment of labour, pain is purely *visceral* in nature. It might also be worth speculating that first stage pain is predominantly C fibre, with an increasing contribution from Aδ fibres as labour progresses. Our knowledge of spinal opioids, which block C-fibre discharge more effectively than Aδ fibres, and are more useful in the first than in the second stage of labour, supports this hypothesis.[10] [11] Such a hypothesis might explain our findings. An alternative explanation is that increasing concentration is required as the frequency of stimulation of individual pain fibres intensifies. This would be unlikely if frequency dependent block occurs in clinical practice. Studies with bupivacaine indicate that increased frequency of stimulation leads to more profound conduction block.[12]

In summary, we found that as labour progressed, there was a significant increase in the requirements for extradural bupivacaine.

Risk factors for cardiovascular death after elective surgery under general anaesthesia

S. J. HOWELL, Y. M. SEAR, D. YEATES, M. GOLDACRE, J. W. SEAR AND P. FOËX

Summary

A large epidemiological data set was used to identify 115 patients who died from a cardiovascular cause within 30 days of elective surgery under general anaesthesia. For each patient, a control was identified, matched for age (within 5 yr of the patient), sex, operation and consultant. Patients and controls were compared for cardiovascular risk factors in a matched analysis using conditional logistic regression, and a prognostic model was generated. Three risk factors were included in the final model: previous myocardial infarction (odds ratio 3.18 (95% confidence intervals (CI) 1.22–8.28), *P* = 0.018), history of hypertension (odds ratio 1.90 (0.99–3.62), *P* = 0.047) and renal failure (odds ratio 3.56 (1.04–12.10), *P* = 0.043). (*Br. J. Anaesth.* 1998; **80**: 14–19)

Keywords: anaesthesia, general; complications, death; complications, cardiovascular disease; anaesthesia, audit; records, anaesthesia

It is widely accepted that patients suffering from cardiovascular disease represent a particular challenge for the anaesthetist. With modern anaesthesia and perioperative care, major cardiovascular complications after anaesthesia and surgery are uncommon. Forrest and co-workers[1 2] reported 19 deaths and 23 myocardial infarctions in a population of 17 201 patients who underwent surgery under general anaesthesia. However, cardiovascular complication rates of 2–6% occur not infrequently in extant reports.[3–5] Such complications result from the intervention of anaesthesia and surgery rather than from any underlying disease, and even a relatively low complication rate is a cause for concern.

Study of the perioperative risk associated with cardiovascular illness is difficult. Most studies of cardiovascular risk factors and perioperative cardiovascular complications have been prospective or retrospective cohort studies.[3 5–11] The relatively low frequency of complications implies that such studies have to include a large number of patients in order to achieve adequate statistical power. An alternative approach is that of the case-control study. This study design is particularly useful for studying rare outcomes and for examining several risk factors simultaneously. Because most of the available studies are cohort studies it could be argued that they may be subject to some form of systematic bias. A case-control study which achieved similar results to the cohort studies would add weight to the validity of findings from each type of study.

We have used the Oxford Record Linkage Study (ORLS), which is a large epidemiological data set, to conduct a case-control study of risk factors for cardiovascular death after elective surgery under general anaesthesia.

Analysis of a subset of the data taken from the ORLS has been undertaken previously to examine the effects of admission arterial pressure and diagnosed hypertension on cause of death.[12] In this article some of these patients have been included together with more patients from the same data set, but all have been re-analysed with regard to this extended list of variables that we have included in our analysis. Overall, we have included 75 patients from the previous dataset, with 40 additional patients.

Patients and methods

DATA COLLECTION

The Oxford Record Linkage Study (ORLS) covers approximately 1.9 million people within the former Oxford Regional Health Authority area. It includes routine data on all hospital admissions for individuals treated within the study area. All stays in hospital, both by in-patients and day cases, are recorded and entered in the database. Patient characteristics and diagnostic data are recorded. All operations are noted and coded. Hospital records are linked to death certificates. For the current study we obtained data on patients who underwent surgery between 1979 and 1990. Patients studied underwent surgery at one of three hospitals in Oxford, or at hospitals in Banbury or Kettering. The choice of hospitals was determined by the availability of case notes in medical records departments for detailed study. The overall population of the study area was approximately 800 000. In the years covered by the study, the SMRs for circulatory disease in general and for ischaemic heart disease in particular were both approximately 88 for men and 93 for women in 1979 and were in the mid-80s for both men and women by 1990.

The ORLS was analysed to identify patients who died within 30 days of anaesthesia and surgery and

Correspondence to S. J. H.

whose death certificates included ICD9 codes (9th International Classification of Diseases) in the range 401–438 inclusive, at any position on the death certificate. The diseases covered by these codes are hypertensive disease (401–405), ischaemic heart disease (410–414), diseases of the pulmonary circulation (415–417), other forms of heart disease (420–429) and cerebrovascular disease (430–438). Patients who died after a pulmonary embolism (code 415.1) were excluded, as were those undergoing cardiac or neurosurgery. It was recognized that there are specific codes available within ICD9 for complications associated with anaesthesia (e.g. 995.4 for shock as a result of anaesthesia). These codes had not been used as certified causes of death on death certificates for any patient in the study population.

CONTROLS

For each patient at least one control was identified. Where possible two controls were identified to allow for the possible non-availability of the medical records of the first control examined. Controls were matched with patients on the following criteria:

- underwent the same operation as the patient,
- under the care of the same consultant as the patient,
- age within 5 yr of the patient,
- same sex as the patient.

When two controls were obtained, one was chosen at random and the notes obtained. If these were unavailable or if the control was excluded for any reason, the notes of the second control were examined.

EXAMINATION OF MEDICAL RECORDS

The medical records of patients and controls were obtained. As required by the local Ethics Committee, we obtained consent to examine the medical records from the consultant caring for each patient during admission for surgery. Where the consultant had died or retired, consent of his or her successor was obtained. The notes were examined in detail by a research nurse. Whenever possible, it was confirmed from the notes that the cause of death given on the death certificate was supported by the medical records. If a patient had clearly not died from a cardiovascular cause, he or she was excluded from the study. Patient data and data on cardiovascular risk factors were collected.

EXPOSURES OR RISK FACTORS

Data were collected on the following risk factors.1

Treated hypertension, angina and heart failure0

A patient was defined as having one or more of these conditions if they had been receiving medication for the condition in question. This was felt to be more reliable than depending on these diagnoses being mentioned in the notes as there was likely to be considerable variation between subjects as to whether systematic enquiry had been made for co-morbidity and as to whether this information was recorded. Drug history is recorded more consistently and can usually be corroborated from drug charts filed in the notes.

Where the term hypertension is used in this article, it refers to treated hypertension. It is important to note that this definition of hypertension was independent of admission arterial pressure.

Previous myocardial infarction, previous cerebrovascular accident, diabetes mellitus, peripheral vascular disease

Patients were considered to have one or more of these conditions if the medical records indicated this to be the case. For these conditions we believed that we could not rely on treatment history to indicate disease. Patients who have suffered a significant myocardial infarction or have peripheral vascular disease may not be receiving cardiovascular medications. Diabetes controlled with diet alone may cause significant end-organ damage.

Renal failure

Patients were said to have renal failure if they had a creatinine concentration >150 μmol litre^{-1} at admission for surgery.

DATA HANDLING

A computer database written using Microsoft Access 2.0 was used to store and examine the data. Microsoft Excel 5.0 was used to examine the tables produced by Access. Statistical analysis was performed using Stata version 4.0. Data were exchanged between the various programs using DBMScopy version 5.10.

STRATEGY OF ANALYSIS

Data were examined for errors and inconsistencies and descriptive statistics produced. Crude odds ratios were calculated and the data were examined using McNemar's test. Where one of the cells in the contingency table had a zero value, exact probabilities were calculated. Because the age difference within pairs could be up to 5 yr, there was potential for residual confounding by age within pairs. It was found that this was best adjusted for by including in the analysis each subject's deviation from the mean age of that matched pair. Adjustment for age difference within pairs was made using conditional logistic regression and these adjusted odds ratios are reported for each risk factor.

Multivariate analysis was performed using conditional logistic regression, the strata being identified by pair numbers linking the patients and matched controls. The aim was to produce a prognostic equation for perioperative cardiovascular death. Terms which were statistically significant at the 0.05 level using the log likelihood test were included in the final regression equation. We also report the result of the Wald test for each term in the final equation. This test is based on a normal approximation to the log likelihood. Terms which were significant on log likelihood testing were included in the final model, even if not quite significant at the 0.05 level by the Wald test.

Table 1 Results for individual risk factors. Concordant and discordant pairs

	No. of pairs			
	Case exposed/ control unexposed	Case unexposed/ control exposed	Case exposed/ control exposed	Case unexposed/ control unexposed
Myocardial infarction	25	6	5	79
Angina	24	7	3	81
Hypertension	39	16	15	45
Renal failure	18	4	0	93
Heart failure	24	9	1	81
Peripheral vascular disease	10	4	18	83
Cerebrovascular accident	13	6	0	96
Diabetes mellitus	13	14	2	86

As with the analysis for individual risk factors, a term for deviation of each subject from the mean age of that pair was included in the model. It was not possible to examine the main effects of exposures on which the subjects had been matched, that is age, sex, type of surgery and consultant. However, interactions between these exposures and hypertension were examined. Potential interactions between the various risk factors were also examined.

Results

We identified 177 patients who died from a cardiovascular cause within 30 days of elective surgery under general anaesthesia; 115 of these patients were selected for further study, together with the same number of individually matched controls. Thirty-seven patients were excluded because the notes of either the patient or the control, or both, were missing. Twenty-five patients were excluded because no matching control could be identified.

Mean age of the patients was 72.6 (range 45–93) yr and that of the controls 71.3 (43–90) yr. Mean age difference between the patients and controls was 0.63 (SD 1.82) yr. Pairs were matched for sex. In 74 (64%) of the pairs the patient and control were male.

Patients and controls were matched for operation. In 29 (25%) pairs, the patient and control underwent abdominal surgery, in 11 (10%) vascular surgery, in 12 (10%) hip replacement surgery and in 63 (55%) pairs other surgery. The other surgery group included patients undergoing endoscopic procedures, including TURP and cystoscopy, in addition to operations such as inguinal hernia repair and Keller's procedure.

Among the patients the mean time from operation to death was 8.4 days (median 6 days). Seventy-eight (68%) of the patients died of myocardial infarction or ischaemic heart disease, 23 (20%) died of heart failure and in 14 (12%) patients the cause of death was cerebrovascular accident. The number of concordant and discordant pairs for each risk factor is shown in table 1.

RISK ASSOCIATED WITH INDIVIDUAL RISK FACTORS

The crude odds ratios for perioperative cardiovascular death are reported for each risk factor in table 2. Table 2 also gives the odds ratios adjusted for residual confounding by age. After adjustment for residual confounding by age, histories of myocardial infarction, angina, hypertension, renal failure and heart failure were observed to have a significant effect on the risk of perioperative cardiovascular death. The odds ratio associated with a history of myocardial infarction was 4.04 (95% confidence intervals (CI) 1.60–10.19; P = 0.003). The odds ratio associated with a history of angina was 3.55 (1.48–8.82; P = 0.004). For a history of treated hypertension the odds ratio was 2.53 (1.38–4.69; P = 0.003). The odds ratio associated with renal failure, defined as a serum creatinine concentration >150 µmol litre^{-1}, was 4.23 (1.36–13.20; P = 0.013). For a history of heart failure requiring medical treatment the odds ratio was 2.80 (1.23–6.41; P = 0.014). The odds ratios for a history of peripheral vascular disease, cerebrovascular accident or diabetes mellitus were not statistically significant.

CONDITIONAL LOGISTIC REGRESSION

The data were then examined by forward stepwise conditional logistic regression. The final model is reported in table 3.

In the final regression model two risk factors (myocardial infarction and renal failure) were significant at the 0.05 level, and hypertension reached borderline significance at this level. The coefficient adjusting for residual confounding by age was also significant at the 0.05 level and its inclusion had a significant impact on the values of the other regression coefficients. No significant interaction terms were identified.

The coefficient for myocardial infarction in this equation was 1.16 (SEM 0.49), giving an odds ratio of 3.18 (95% CI 1.22–8.28) and a P value of 0.018 by the Wald test. The coefficient for hypertension was 0.64 (SEM 0.33), giving an odds ratio of 1.90 (95% CI 1.00–3.62). The Wald test for the effect of

Table 2 Results for individual risk factors. Crude and age-adjusted odds ratios

Peripheral vascular disease	2.5 (0.72–10.95)	2.57 P=0.1088	3.01 (0.84–10.80)	1.69 P=0.91
Cerebrovascular accident	2.67 (0.77–6.95)	2.58 P=0.1083	2.42 (0.86–6.85)	1.67 P=0.94
Diabetes mellitus	0.93 (0.40–2.13)	0.04 P=0.85	0.89 (0.40–2.00)	0.28 P=0.78

Table 3 Final conditional logistic regression model for risk factors for cardiovascular death after anaesthesia and surgery

	Regression coefficient (SEM)	Odds ratio (95% CI)	Chi-square (comparison of likelihoods)	*P* value (comparison of likelihoods)	*z* (Wald test)	*P* value (Wald test)
Myocardial infarction	1.16 (0.49)	3.18 (1.22–8.28)	6.50 1 df	0.011	2.37	0.018
Hypertension	0.64 (0.33)	1.90 (1.00–3.62)	3.95 1 df	0.047	1.95	0.052
Renal failure	1.27 (0.63)	3.56 (1.04–12.18)	4.75 1 df	0.029	2.02	0.043
Age difference	−0.19 (0.06)	0.83 (0.73–0.93)	10.1 1 df	0.0015	2.96	0.003

hypertension was not quite significant at the 0.05 level ($z = 1.95$, $P = 0.052$). The Wald test is based on the normal approximation to the log likelihood. A comparison of the log likelihoods associated with models including and excluding hypertension (log likelihood ratio test) yielded a value of chi-square = 3.95, P=0.047, 1 df. Hypertension was therefore retained in the model.

The coefficient for renal failure was 1.27 (SEM 0.63). This translated to an odds ratio for renal failure of 3.56 (95% CI 1.04–12.18). The Wald test for the coefficient for renal failure was significant at the 0.05 level ($z = 2.02$, $P = 0.043$).

Discussion

FINDINGS

When adjustment was made for residual confounding by age, but not for other confounding factors, five risk factors were found to be significantly associated with cardiovascular death within 30 days of anaesthesia and surgery. These were previous myocardial infarction, history of angina, history of hypertension, history of renal failure and history of heart failure. In the conditional logistic regression model derived by stepwise regression, myocardial infarction and renal failure were found to be significant risk factors ($P <$ 0.03), with hypertension at a borderline level of 0.052.

It was found that angina made a significant contribution to the regression model if a history of myocardial infarction was not included in the equation. When a history of myocardial infarction was included in the model the term for angina ceased to be significant. That is to say, most of the risk caused by ischaemic heart disease could be accounted for by the term for myocardial infarction.

Much of the heart failure reported in this population was probably a result of ischaemic heart disease or hypertension. The absence of heart failure in the final regression model may be accounted for by the inclusion of terms for myocardial infarction and hypertension. In the absence of these terms, heart failure made a significant contribution to the model.

Failure to find a perioperative risk associated with diabetes mellitus is difficult to explain. It may be that there was a bias in the recording of the cause of death in diabetics, such that some perioperative cardiovascular deaths of diabetics were coded as being caused by diabetes rather than by a cardiovascular event.

METHOD OF ANALYSIS

A predictive or prognostic equation, such as the one reported here, is useful for identifying patients at risk. However, a distinction should be made between predictive and explanatory models. A predictive equation aims to predict outcome on the basis of the patient's exposure to risk factors, but it does not necessarily give an accurate impression of the importance of individual risk factors. An explanatory equation is intended to give the best possible estimate of the effect of one or more risk factors.[13 14] The distinction can be illustrated using the current data. There is a complex interaction between various cardiovascular risk factors. One risk factor may lie on the causal pathway for the effect of another. For example, hypertension has a role in the pathogenesis of ischaemic heart disease and patients with hypertension are more likely to have suffered myocardial infarction. A history of myocardial infarction may account for some of the perioperative cardiovascular risk associated with hypertension. Our prognostic equation included both hypertension and myocardial infarction. Adjustment for myocardial infarction may reduce the effect of hypertension. Thus the regression coefficient for hypertension may not reflect the full impact of hypertension on risk.

COMPARISON WITH OTHER STUDIES

For the most part, our findings were similar to those of other workers. Many studies, including those of Goldman and colleagues,[6] Larsen and colleagues[5] and Fowkes and colleagues,[7] have identified an association between previous myocardial infarction and perioperative cardiovascular complications. An association between renal impairment and adverse outcome has also been demonstrated in other studies.[9 11]

There are some interesting contrasts with other studies. The effect of a history of hypertension on adverse outcome is not clearly established. Prys-Roberts, Meloche and Foëx demonstrated associations between poorly controlled hypertension, intraoperative cardiovascular instability and myocardial ischaemia.[15] The multicentre study of general anaesthesia conducted in North America found an association between preoperative hypertension and perioperative bradycardia, tachycardia and hypertension.[1] Browner, Li and Mangano identified an association between history of hypertension and mortality after major non-cardiac surgery.[11] In contrast, hypertension was not found to be a significant risk factor on multivariate analysis in the studies of Foster and colleagues,[8] Pedersen, Eliasen and Henriksen,[10] Larsen and colleagues[5] or Goldman and colleagues.[6]

We found heart failure to be a risk factor on univariate analysis, but not after adjusting for other risk factors. Other studies have found heart failure or poor left ventricular function to be a risk factor for adverse outcome on multivariate analysis.[5 8 10]

In trying to understand these differences it must be remembered that the various studies examined different populations in different locations, and that the study designs and methods of data collection varied. Goldman and co-workers, and Larsen and colleagues, studied patients more than 40 yr of age undergoing both elective and emergency non-cardiac surgery.[5,6] Fowkes and colleagues[7] examined outcome after all 108 878 anaesthetics given in Cardiff between 1972 and 1978. Pedersen, Eliasen and Henriksen studied all patients undergoing anaesthesia in one hospital over a 1-yr period, no lower or upper age limit being specified for the inclusion of patients.[9,10] Browner, Li and Mangano studied US veterans aged 38–89 yr undergoing major non-cardiac surgery.[11] Shah and colleagues studied patients who were more than 70 yr of age or known to have cardiac disease.[3] The observations of Forrest and co-workers were made in the context of a multicentre, randomized study of four different anaesthetic agents.[2] Also, the end-point used varied from study to study. We took cardiovascular death as an end-point. In the study by Shah and colleagues, the end-points were identified by review of the medical records and included angina, myocardial infarction, heart failure and cardiac death.[3] Goldman and colleagues[6] used adverse cardiovascular events as identified by the study observers and confirmed on diagnostic testing, while Foster and co-workers[8] used cardiovascular events reported to the CASS registry. Given these differences, the relative consistency of the different studies is encouraging, while the fact that there are some differences both between the studies and between our findings and those of other workers is not surprising. These differences may result in part from random error or in part from real differences between the populations studied.

WEAKNESSES OF THE STUDY

Patients in this study were selected from the Oxford Record Linkage Study on the basis of a cardiovascular cause of death recorded in any of the sections of their death certificate. It is well established that diagnoses recorded on death certificates often do not reflect the true cause of death.[16,17] Using the medical records it was possible to identify patients who had suffered a series of surgical and medical complications before death, and it appeared that a diagnosis of heart failure or cardiac arrest had been seized upon to simplify an otherwise very complex picture. Many of these misdiagnoses could be identified from the medical records and such patients were excluded. It is possible, however, that in some cases a diagnosis of cardiovascular death was mistakenly taken at face value.

The research nurse who examined the medical records could not be blinded to the patient/control status of subjects as outcome was usually clearly recorded in the notes. The question therefore arises of possible observer bias in the recording of data on hypertension. This problem was addressed by the use of a data collection tool which demanded specific responses to a series of questions rather than asking more general questions about the observer's impression of the course of events.

It could be argued that this study was overmatched in the manner described by Rothman.[18] That is, the matching criteria were demanding and it proved impossible to match 25 subjects, so reducing the efficiency of the study. Matching on type of surgery was probably justified in that this is a potential confounder which has many categories and is difficult to quantify more simply. Matching on consultant may also be justified. Matching on age was probably necessary to avoid the possibility of identifying controls who were appreciably younger than the patients. It would have been possible to control for age in the analysis and at the same time gain information on the association between age and adverse outcome. Frequency matching would have been sufficient. The effect of sex could possibly have been controlled in the analysis. Without matching on sex, information could have been gained on the effect of sex on perioperative risk. Finally, matching on date of surgery would have been useful and was attempted, but led to the loss of a large number of pairs through failure to match.

CONCLUSIONS

Our study is consistent with previous work in identifying myocardial infarction and renal failure as risk factors for perioperative cardiovascular complications. Unlike some previous studies, we did not identify heart failure as a risk factor on multivariate analysis. In this study, where data were examined by multivariate analysis, hypertension achieved a significance level of $P = 0.052$ for adverse outcomes. Although univariate analysis of this dataset and that of our previous publication suggested a strong association between hypertension and adverse outcome, such a statistical approach does not take into account other confounding factors.
